ABSTRACT

Founded on the teachings of Mevlâna Jalaluddin Rumi (1207-1273), the sufi order of Mevlevî dervishes existed for over 600 years. It spread from its centre in Konya by establishing Mevlevî dervish lodges called mevlevîhânes, which were divided into the two categories of asitânes and zaviyes according to their function and capacity. Asitânes were larger architectural complexes administrated by a shaykh and teaching staff of dervishes called dedes where dervishes could undergo a 1001 day of spiritual training, whereas zaviyes were smaller mevlevîhânes without this capacity and training programme. On the closure of all the dervish lodges in 1925, there were almost 200 mevlevîhânes and 14 asitânes in existence. This study focuses on the architectural site plan changes within the complex of the Bursa Mevlevîhâne Asitâne during the 19th century. By examining its rich supply of historical maps, archival plans and photographs, it is possible to trace the locations of units such as stables, gasilhâne, main kitchen, toilets, laundry-drying gardens etc. which are almost unknown in other mevlevîhânes. It is hoped that this study will also contribute to the documentation of the original data of the structures and layout of the site plan of Bursa's last functioning mevlevîhâne in 1925, so that a correct restitution and reconstruction of the complex can be made possible.

Keywords: Bursa Mevlevîhâne Asitâne, Asitâne, Mevlevîhâne Architecture.

1. INTRODUCTION

Due to its geographical location, Bursa became the first capital of the Ottoman Empire and the intersection of many civilizations and cultures. All the civilizations that occupied Bursa increased the value of the city which has many monumental and civilian architectural structures. The Bursa Mevlevîhâne Asitâne is one of these structures. Based on the teachings of Mevlâna Jalaluddin Rumi, the Mevlevî sufi order, was established in Konya in the late 13th century and spread throughout the Ottoman Empire. Smaller mevlevîhânes were called zawiya, while the larger ones equipped to provide the 1001 day of spirutal training were called *asitânes*. An asitâne was a building complex that included all the sections for the functions of worship, education, accommodation, nutrition, cleaning and visitation (Tanrıkorur, 2004, 468-471). Sometimes a structure within the complex was used for more than one function.

An asitâne built on a large plot of land, had a *semahâne*, a large assembly hall where the ritual ceremony of sema (whirling movements) called *Mevlevî Ayini Sherif* were held; a *meydan-ı sherif* where the meetings of the administrative staff were made after the morning prayer and important decisions were made; a *türbe-i sherif*, tomb area where the founding shaykhs were

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

buried; a *hamusan* (the graveyard of the silent ones) where dervishes and members of the mevlvihane were buried. As in residential architecture, accommodation units were divided into two main groups, *harem* quarters for the shaykh's family and female dervishes and *selamlık* quarters for male dervishes. The shaykh and his family lived in the harem quarters and female dervishes were given lessons there. The selamlık quarters was where male guests were hosted and male dervishes held meetings and practised music. In addition there was a row of cells for the *dedes*, those senior dervishes who had completed their 1001 days of spirital training and who had achieved the rank of "dede". One of the most important sections of an asitane (which was not found in a zaviye) was its *matbah-ı sherif* section which was designated solely to the 1001 day of training and housing of new initiates called *çilekeş canlar*. On the other hand, there existed a separate main kitchen, where a *somathane* (dining room), cellars, bakery and other facilities for daily food and beverage needs of the mevlvîhâne were met. In mevlvihanes, there were other elements such as a *hamam* (bathing areas), a *gasilhane* (for preparing the dead for burial), places for making ablutions ranging from simple taps to fountains, cisterns, wells and pools for water needs could be found (Tanrıkorur, 2000, 89-101). Since transportation was mostly by horse and donkey stables were available as well as boathouses in mevlvîhânes located by the sea (Tanman, 2013, 51-52).

The Bursa Mevlvîhâne asitâne is one of the 14 asitânes (Afyonkarahisar, Bursa, Eskişehir, Gelibolu, Aleppo, Cairo, Kastamonu, Kütahya, Manisa and Yenişehir and four –Galata, Yenikapı, Beşiktaş, Bahariye, Kasımpaşa- in İstanbul) which were built during the Ottoman period (Tanman, 1991, 487).

This study focuses on the site plan of Bursa's last functioning mevlvîhâne before its closure in 1925. Firstly, in the short historical introduction the founding, location of the geographical area of the Bursa Mevlvîhâne Asitâne will be explained. Secondly, with the available source data, the historical process involving the changes (expansion, reconstruction, repair) to the Mevlvîhâne up until 1925, when its functioning as a dervish lodge ended, will be discussed using maps, site plans and photographs. Next, the changes between 1925 to 1953, when the demolition process of the mevlvihane began, will be explained. Finally, all these sources will be evaluated and after bringing the site plans, maps and drawings all to the same scale and superimposing them one over each other, a site plan for the year 1925, when the Mevlvîhâne was last functioning, will be drawn and interpreted.

2. The Bursa Mevlvîhâne Asitâne

The Bursa Mevlvîhâne Asitâne was built by Shaykh Ahmet Cünunî Dede in the Veziri neighborhood of the Pınarbaşı district in 1615, during the reign of Sultan Abdulhamid I, who gave great support to the Mevlvî order. There is no detailed information about the first building of the Mevlvî lodge, but some information about the sections of the building can be obtained from its foundation charters. It consisted of three pir houses, two ovens, a garden with various trees and five wells. In addition, a semahâne, similar to a heavenly mansion was built in the garden. The wall between the donated houses was demolished and the other outbuildings of the mevlvihane were constructed¹ (Figure 1).

Figure 1. In 1861-1862 the Bursa Mevlevihâne Asitâne Site Plan (Suphi Bey ve Erkân-ı Harbiyye-i Şâhâne, Mühendishâne-i Berrî-i Hümâyûn, 1278)

3. The Historical Introduction (Widening, Rebuilding, Restorations) of The Bursa Mevlevihâne Asitâne Until 1925

The changes that the Mevlevihâne complex went through until its last period of activity in 1925 when the lodges and zawiya were closed, can be accessed from archival information and other sources. From these it can be seen that many repairs and additions were made to the Mevlevihane complex. In the 18th century Shaykh Ataullah Dede, who was the head of the lodge, applied to the Grand Vizier Derviş Mehmet Pasha in 1190/1776 and had the complex undergo a major repair (Ulusoy, 2020, 469, Kepecioğlu, 2009, 143).

The Mevlevihâne also underwent major repairs during the time of Shaykh Salih Dede (d.1246/1830). Even the semahâne took its final shape during these repairs (Öcalan, 2023, 39). In 1260/1844, when Ahçıbaşı Dede was the shaykh of the lodge, the Mevlevihâne was repaired and redecorated with some additions on the occasion of the arrival of Sultan Abdülmecid in Bursa (Ulusoy, 2020, 474).

In 1274/1857, during the reign of Shaykh Nizamettin Efendi, with the efforts of the Bursa Governor, Süleyman Refet Pasha, the kitchen of the lodge, some of its rooms and the türbe-i şerif (tomb section) underwent a major repairs (Ulusoy, 2020, 478) (Figure 2) (Figure 3).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 2. In 1862 the Bursa Mevlevihane Asitane Site Plan (Suphi Bey ve Erkân-ı Harbiyye-i Şahane, Mühendishane-i Berr-i Hümayun, 1278)

Figure 3. Bursa Mevlevihane Asitane in the 1879 Hisar Map (Elbas & Alkan, 2023, 13)

During the period when Mehmed Şemseddin Dede was the last shaykh, the Mevlevihane was extensively repaired on the request of Bursa's governor Mahmud Celaledin Pasha, and there exist detailed site plans and archival documents related to these repairs dated 1311/1895².

There were two site plans attached to the documents. The first of these is the site plan drawing of the then ("present") state of the dervish lodge in 1311/1895. The second repair site plan especially contained the plan of the buildings to be newly constructed or relocated. According to the first site plan³, on the east side of the mevlevihane's main entrance, there was the türbe-i şerif (tomb section), the mescid-i serif, then a gap that is thought to be a porch next to the

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

dedes cells. To the east of these cells was the courtyard and exit ("küstahan door" through which unsuccessful dervishes were dismissed from the Mevlevîhâne) of the matbah-1 şerif to the Pınarbaşı road. The rooms of the matbah-1 şerif section were located to the north of these. There were toilets to the north of the matbah-1 şerif section, followed by the "gasilhâne" (funeral washing room) and the unconnected "stables-carriage area" to the northeast. On the west side of the main entrance, were the cells of the dedes, the *selamlık* male dervish quarters and the harem quarters, respectively. To the north of these buildings a detached "ruined matbah" was to be found. In the middle, in the north of the main courtyard of the Mevlevihane complex, there was a "semahâne". An "ablution fountain" was located between the semahâne and the tomb area, and there were also several "decorative pools" in various parts of the courtyard (Figure 4).

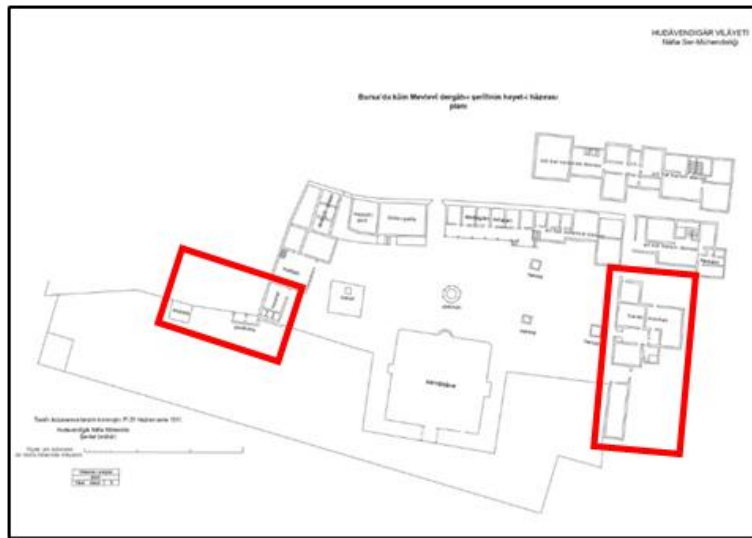

Figure 4. The first 1311/1895 Bursa Mevlevîhâne Asitâne Site Plan in the Ottoman Archives (BOA, Başbakanlık Osmanlı Arşivi, 1895)

In the second repair site plan⁴, on the east side of the Mevlevihane's main entrance from the Pınarbaşı Cemetery side of the mevlevîhâne, there was the türbe-i şerif and mescid-i şerif then the space thought to be a porch and the cells of the dedes.

To the east of these cells was the exit from the courtyard of the mathah-1 şerif to the Pınarbaşı road. To the north of these were located the units of the mathah-1 şerif section. However, the toilets, gasilhâne and stables-carriage area have been removed from this site plan. On the west side of the main entrance were to be found the cells of the dedes, the *selamlık* male dervishes' quarters and harem quarters. To the north of these were to be found a main kitchen and toilets which have been changed in design and dimensions from those in the previous site plan.

However, the semahâne, ablution fountain and decorative pools in the middle of the main courtyard were located in the same places as seen in the first site plan. Noticeable in this site plan are drawings on the west, of the traditional, home-type harem quarters' plans that was to be demolished. (Figure 5).

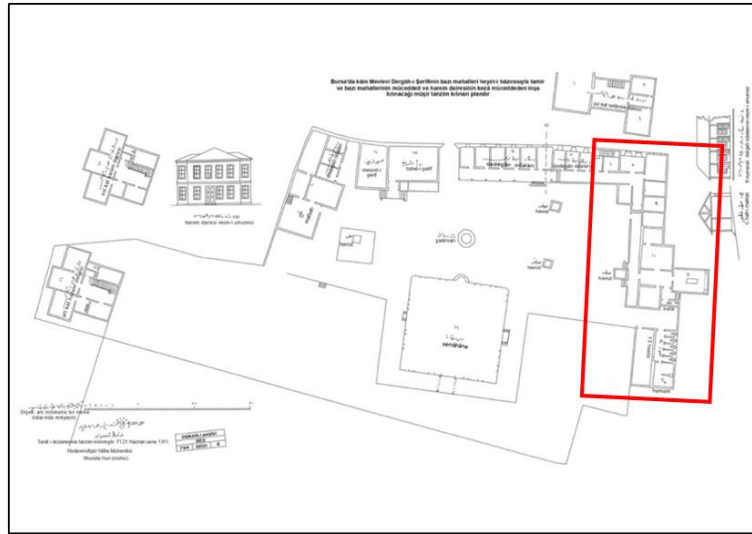

Figure 5. The second 1311/1895 Bursa Mevlevîhâne Asitâne Site Plan in the Ottoman Archives (BOA, Başbakanlık Osmanlı Arşivi, 1895)

4. The History of The Bursa Mevlevîhâne Asitâne After 1925, Until its Demolition in 1953

The Bursa Mevlevîhâne Asitâne continued functioning until 1925, when all dervish lodges were legally closed (Figure 6). After 1925, the *selamlık* quarters of the Bursa Mevlevîhâne were used as military barracks, and ownership of the *harem* quarters was left to the shaykh's family (Ulusoy, 2020, 480).

The semahâne was used as a masjid where the last shaykh, Mehmed Şemseddin Dede, who had been shaykh for 48 years, served as an imam and preacher. After the death of Mehmed Şemseddin Dede in 1931, the semahâne was at different periods of time used as a storehouse, a police station, hayloft and stable. Therefore, the Semahâne, from whose dome ney tunes had risen for almost three centuries, had become ruined due to neglect over time.

Except for the tomb section, the ongoing neglect of the various sections and their inappropriate functional use caused the building sections of the Bursa Mevlevîhâne Asitâne complex to become deteriorated and unusable over time (Öcalan, 2023, 49-51) (Figure 7a.-7b.-7c.).

Figure 7b. The Matbah-ı şerif section, the Meydanı- şerif and the Türbe-i şerif of the Bursa Mevlevîhâne before 1953 (Tanrıkorur, 2000, 178)

Figure 7c. View of the main coudyard, the Türbe-i Şerif, the Dedes' Cells, the Selâmlık Quarters and the ablution fountain of Bursa Mevlevihane before 1953 (Tanrıkorur, 2000, 179)

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

In the cadastral 1934 site plan of the Bursa Mevlevîhâne (Elbas & Alkan, 2023, 14), the borders of the türbe-i şerif and the mescid-i şerif located on the east side of the main entrance can be seen. However, here the cells of the dedes and the area thought to be a porch in the Ottoman archival 1311/1895 site plan, have been combined together and added to the matbah-1 şerif section. Although the borders of the toilets to the north of the matbah-1 şerif section can still be seen in this site plan, the *gasilhane* and stables-carriage units found in the Ottoman archival 1311/1895 site plan have disappeared as a result of the change in the boundaries of the north-eastern parcel (the sales, ownership change). The semahâne, the ablution fountain and decorative pools in the main courtyard can still be seen in this site plan. While the borders of the dedes' cells and the initial spaces of the selamlık quarters are visible on the west side of the main entrance, the harem quarters, main kitchen and toilet sections are not visible in this site plan due to the later changes which had been made to the parcel boundaries (Figure 8).

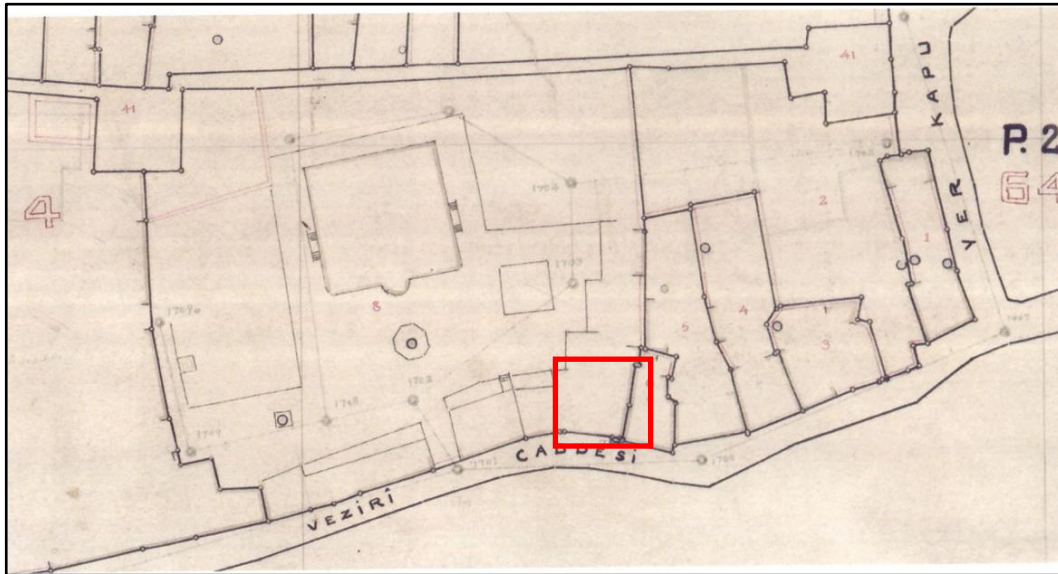

Figure 8. The 1934 Bursa Mevlevihane Cadastral Site Plan in the Bursa General Directorate of Foundations Archives (Elbas & Alkan, 2023, 14)

Although the Mevlevîhâne was in a ruined state, it had been able to survive until 1953 with the above-mentioned building units intact. However, upon the report prepared by Architect Ali Saim Ülgen on behalf of the General Directorate of Foundations in 1953, stating that the Mevlevîhâne was at risk of being ruined and that there was no budget for its restoration (Elbas & Alkan, 2023, 34), the Bursa Municipality informed the High Council of Historical Real Estate and Monuments that it wanted to build a water reservoir on the Mevlevîhâne plot of land. Although the legal process was still ongoing and the demolition decision had not been legally made, the Municipality started demolition works and constructed a water tank on the Mevlevîhâne plot of land (Öcalan, 2023, 51) (Figure 9).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Figure 9. The water tank construction works in the Bursa Mevlevîhâne garden, 1953 (Elbas & Alkan, 2023, 37)

When the site plans of the Mevlevîhâne before and after 1953, found in in the archives of the General Directorate of Foundations (Elbas & Alkan, 2023, 18-19), are compared and evaluated, it can be seen that before 1953 (1) the semâhâne, ablution fountain (2) türbe-i şerif, (3) dedes' cells, (4) meydan-ı şerif, and (5) matbah-ı şerif sections were still present in the complex, while in the site plan after 1953 the (1) semâhâne and ablution fountain have completely disappeared due to the construction of a water reservoir. Except for (2) the tomb unit and (3) ruined dervish cells all the other units have been demolished (Figure 10).

Figure 10. The Bursa Mevlevihane Site Plans before and after 1953 in the Bursa General Directorate of Foundations Archives (Elbas & Alkan, 2023, 18-19).

5. The Proposed Site Plan of the Bursa Mevlevîhâne Asitâne Around 1925

In the preparation of the site plan of the last functioning Bursa Mevlevîhâne Asitâne of around 1925, a meticulous study was made of all the archival records' information of the Mevlevîhâne, the site plans, maps, drawings and photographs which were evaluated historically.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

In the interpretation of the site plan of the Bursa Mevlevîhâne Asitâne around 1925, it can be seen that the connection of the Mevlevîhâne with Pınarbaşı Road is provided through 3 connections.

These are respectively (1) the main entrance of the Mevlevîhâne, (2) the matbah-1 şerif road exit (the küstahan door), and (3) the entrance to the harem quarters. After entering through the main entrance of the Mevlevîhâne, there is (4) the türbe-i şerif (tomb section) on the east side. Access to this building is from the porch, which is accessed from the main courtyard by three steps. There is also a small grave area called “*hamusan*”, in front of the tomb section facing the main courtyard. Next to the tomb section, there is (5) the rectangular planned meydan-1 şerif (labeled *mescid-i şerif* in the Ottoman archival plans) extending perpendicular to the courtyard. Then according to the information in the 1934 Cadastral site plan and 1953 photographs (6) the matbah-1 şerif section was drawn so that the dede cells and area thought to be a porch in the 1311/1895 site plan of Ottoman archival were combined and added to the matbah-1 şerif section. As seen in the 1311/1895 site plan of the Ottoman archives, (7) the toilets were drawn located to the north of the matbah-1 şerif section, followed by (8) the gasilhane while (9) the stables-carriages area were located independently from these units. (10) The arbor with a pool in the courtyard of the matbah-1 şerif section, (12) the semahâne and (13) the ablution fountain in (11) the main courtyard were drawn by evaluating all the archival site plans. On the west side of the main entrance, (14) 3 cells in a row with a front porch for the dedes, accessible from the courtyard were drawn with the help of old photographs (Photo 7c). At the end of these cells were located (15) the coffee preparation room and then (16) the *selamlık* male dervishes' quarters which was accessed by stairs from the porch. To the west of the *selamlık* quarters, (17) “the harem living quarters” for the shaykh's family and female dervishes was drawn according to the VGMA building survey plan drawings dated 1953, by R. Bediz and T. Kölük⁵.

In accordance to the data in the 1862 site plan map of Suphi Bey (Photo 2), the open area to the west of the harem quarters was drawn, with (18) the laundry-drying garden, the garden behind the harem with (19) its arbor and decorative pool and (20) rose gardens. To the northeast of the harem quarters, (21) the main kitchen, bakery-dining rooms for daily meals, (as seen located in the ruins, in the 1311/1895 site plan) and the outside (7) toilets were drawn.

The open area north of the *selamlık* male dervish quarters was drawn (22) as a courtyard with its three (23) decorative pools. The open area located on the embankment to the north of this courtyard was determined as (24) the vegetable and fruit gardens of the Mevlevîhâne in accordance with the data in the 1862 site plan map of Suphi Bey.

Finally, (25) the Bursa City fortress wall found in all the archival site plans was drawn in its location as the northern boundary of the Mevlevîhâne plot of land (Figure 11).

6. CONCLUSION

The Bursa Mevlevîhâne Asitâne, which had been a major part of the spiritual and artistic life of the Mevlevî sufi order in Bursa for almost three centuries, was an important asitâne building complex in Anatolia, whose sections fulfilled the functions of worship, education, visit, shelter, eating-drinking and cleaning. The Mevlevîhâne, which had functioned from the date of its first building in the 17th century to 1925 had undergone many changes of expansion, repair and restoration. After 1925, while some of the construction units continued to function, some of them were used for other different functions. However, over time, they too became ruined due to neglect and abandonment. In 1953, it was claimed that the Mevlevîhâne was in ruins and that it was a risk and that there was no budget for its restoration. Therefore the demolition of the Mevlevîhâne began with the decision to build a water tank in its site area.

This study, aimed to create original data about the structures and site plan of Bursa's last Mevlevî Lodge, while it was still functionally active around 1925. To this end, the architectural site plan changes in the Bursa Mevlevîhâne Asitâne complex were evaluated by examining the rich supply of historical site plans, maps, drawings, and photographs available in the archives. Then all the site plans were brought to the same scale and superimposed one over each other, from which our proposed original site plan of the functioning Bursa Mevlevîhâne complex around 1925 was drawn. In the drawing, were placed the stable-carriage area, the *gasilhâne*, the main kitchen, the toilets, the laundry-drying garden, the rose, fruit and vegetable gardens, which were all in use at that time. It is hoped that this study will act as a guide to the correct restitution and reconstruction process of the complex; as well as revealing original data about the structures and site plan of Bursa's last actively functioning Mevlevîhâne around 1925.

Thanks and Information Note:

We would like to thank the staff of the Bursa Metropolitan Municipality Social Services Department, for their information and help regarding the Bursa Mevlevîhâne Asitâne.

ABSTRACT

Woodwork, which came to the fore in the Turkish-Islamic architecture of the Seljuk and Principalities periods, also manifested itself in the Ottoman period. In these periods, advanced examples of woodwork are encountered both in terms of construction technique and ornamentation. Kundekari has an important place in traditional woodwork. There are types such as real künde-kari and imitation künde-kari in the art of künde-kari, in which a geometric composition is created by interlocking small geometric pieces. Real künde-kari examples, in which wooden pieces are interlocked without the use of nails or glue, are found in different parts of many historical buildings. Historical mosques are among the most important buildings where künde-kari examples are seen. Kundekari art is frequently encountered in the doors, pulpit and window shutters of historical mosques. The aim of this study is to provide restoration suggestions for the preservation of the door of the Behram Pasha Mosque in Diyarbakır and to transfer it to the future. The scope of the study consists of the wooden door wings of the Behram Pasha Mosque made with kundekari technique. In the study, the wooden door wings were examined on site. During the examination, photographs of the door wings were taken and measurements were taken. Using the measurements and photographs, a drawing of the door was made in computer environment. As a result, the missing geometric parts required for the integration of the wooden door wings of Behram Pasha Mosque were identified and a restoration proposal was developed for the door wings.

Keywords: Behram Pasha Mosque, Woodwork, Wooden Door Wings, Kundekari, Restoration.

1. INTRODUCTION

In the early periods when wood was used as an ornamental element in buildings, geometric patterns were drawn on one-piece wooden panels, and depth was given to the drawings. These panels were brought together on the surface where the wood would be used, and the surface was covered. The wooden panel, which was a single piece, was cracked into pieces in the historical process, and the integrity of the panels was disrupted by moving away from each other. This problem was solved by the künde-kari technique, in which large surfaces are formed by bringing small pieces of wood together using a channel system without any binder (Eyigün and Metin, 2007).

Defined as ornamentation consisting of small interlocking timbers, künde-kari is a production technique used in Seljuk and Ottoman period woodwork (Söğütü, 2004; Sözen and Tanyeli, 1986; Ödekan, 1997; Tufani, 1980).

The main purpose of using the künde-kari technique is to prevent problems arising from the expansion and narrowing of wood, which is an organic material, by being exposed to external influences (Soysal, 2007; Büyükçanga, 2000).

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Söğütlü (2004) defined künde-kari as *"the construction technique applied in the interlocking joining of geometrically shaped, small-sized parts such as triangles, squares, stars, and pentagons in order to obtain large and decorative surfaces with reduced internal stresses in order to enable the work that can be carried out with the effect of the relative humidity and temperature change of the environment in which it is used"*. According to the production method, künde-kari is divided into two categories: real and imitation.

In the real künde-kari technique, the pieces are joined by means of grooves without using fixatives such as nails (Kürklü, 2011; Yüksel et al., 2016). In imitation künde-kari, where the construction method in real künde-kari is ignored and visual success is imitated to obtain a künde-kari appearance, the parts are connected to each other with fasteners, requiring less mastery (Özdemir, 1999; Söğütlü, 2004; Soysal 2007).

The künde-kari examples that have survived from the old periods to the present day reveal the durability of the products made with this technique. These artefacts reflect the transition from eastern culture to western culture as well as the aesthetic characteristics of their periods.

The use of the technique, which was extensively used in Seljuk and Ottoman mosque doors, minbars, and shutters, has decreased in recent years. In addition to the benefits it provides in construction, the fact that few works produced with the künde-kari technique have survived to the present day makes the künde-kari technique valuable (Yüksel et al., 2016; Sönmez, 2001).

The entrance door of Behram Pasha Mosque, which is an Ottoman period building, is a work made with the künde-kari technique. The door, which has survived from the period when it was built to the present day and continues its existence in its original place, is important in terms of reflecting the style of the period and being an example where the künde-kari technique is applied. When the studies in the literature were examined, no study on the documentation and restoration of the door of Behram Pasha Mosque was encountered.

Documenting the door and transferring it to the future is important for the sustainability of our cultural heritage. For this reason, the study aims to document the wooden door of Behram Pasha Mosque and develop a restoration proposal for the door to be transferred to the future.

2. MATERIALS and METHODS

Behram Pasha Mosque, located close to the Mardin Gate within the Diyarbakır Walls, is located on Bayrampaşa Street in the Abdaldede neighborhood (Figure 1).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Figure 1. Behram Pasha Mosque location (Google Earth)

It is known that the building was built between 1564 and 1572 by Behram Pasha, the 13th Ottoman governor of Diyarbakır. According to *Tuhfetü-l Mimarın*, the building is known to be a work of Mimar Sinan (Sözen, 1971).

The garden of the mosque is entered through the gates in the north, east, and west directions. In the center of the garden is an octagonal fountain sitting on eight columns. To the south of the fountain is the main structure of the mosque. The building has a square plan and is covered with a single dome sitting on an octagonal pulley. To the north of the harim is the last congregational place. This area has a double portico. This feature distinguishes the building from other Diyarbakır mosques (Karaca, 2017). While the inner portico consists of five domes, the outer portico was built in a flat shape (Figure 2).

Figure 2. Behram Pasha Mosque plan (www.archnet.org)

There is a symmetrical order on the north wall of the harim, opening to the porticoes. This symmetrical order is according to the crown door in the center of the wall. The door protrudes from the facade. The inner surfaces of the door niche were built with black and white stones in alternating patterns. A flattened arch is formed in this system. There is a niche with muqarnas on the molding. This niche is covered with a five-slice arch. On the outer corners of the niche, under the arch, there are recessed columns. The bodies of the columns are plain, and their capitals are muqarnas. After the arches, there is a border surrounding the door. Above this is a pointed arch.

The scope of the study consists of the wooden door wings made with the künde-kari technique of the Behram Pasha Mosque belonging to the Ottoman period located within the historical city walls of Diyarbakır. Since the door wings of Behram Pasha Mosque are made with the künde-kari technique and the door is in danger of disintegration due to the missing geometric parts on the door wings, it is necessary to present a restoration proposal for the door wings.

In the study, wooden door wings were examined on site. During the examination, photographs of the door wings were taken, and measurements were taken. Using the measurements and photographs, a drawing of the door was made on the computer. Then, the missing geometric parts required for the integration of the wooden door wings of Behram Pasha Mosque were identified, and a restoration proposal was developed for the door wings.

3. FINDINGS and DISCUSSION

When the door wings of Diyarbakır Behram Pasha Mosque are analyzed, it is understood that the door is made of wooden material. It is evident that the real künde-kari technique was applied

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

in the construction of the door. It is seen that the door wings are basically composed of inner filling pieces and spine slats derived from three ten-pointed stars in the vertical direction. In addition to the ten-pointed star, the inner filling pieces consist of five-pointed stars, hexagons, deltoids, and new pieces formed by cutting these pieces as a result of coming to the edges (Figure 3).

Figure 3. Behram Pasha Mosque entrance gate

In the study, measurements of the door were taken and drawings were made. By comparing these drawings with the door, missing parts on the door wings were identified (Figure 4). The production of these parts and their placement on the door wings will contribute to the integration of the door.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 4. Drawings of the door wings of Behram Pasha Mosque

The door wings, which are formed by taking the ten-pointed star as the centre, have inner filling pieces and spine laths in different geometric forms (Figure 5).

Figure 5. Drawings of the inner filling parts and spine laths of the door wings of Behram Pasha Mosque

On the wooden door wings of the Diyarbakır Behram Pasha Mosque, it is seen that pattern differences are formed as a result of the opening of the ten-pointed star in the center and its intersection with the parts derived from other ten-pointed stars (Figure 6).

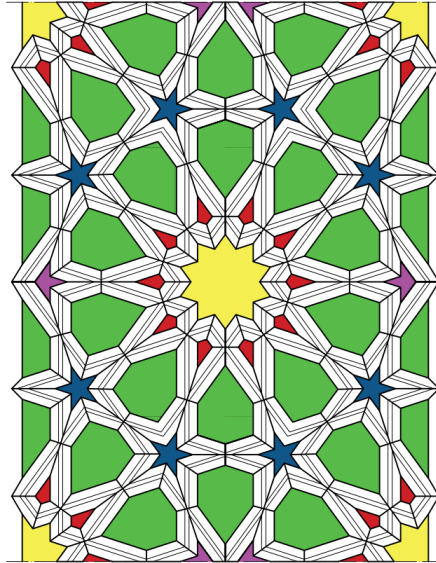

Figure 6. Pattern differences of the door wings of Behram Pasha Mosque

On the wooden door wings of Diyarbakır Behram Pasha Mosque, there are different metal accessories that function as locks and knockers. Although deterioration is also observed on these metal accessories, the presence of missing parts draws attention (Figure 7).

Figure 7. Metal accessories on the door wings of Behram Pasha Mosque

4. CONCLUSION and RECOMMENDATIONS

Diyarbakır Behrampaşa Mosque is important both for its historical value and for being a work of Mimar Sinan. Due to the fact that the mosque has a double portico, the structure stands out among Diyarbakır mosques. In the historical process, deterioration has occurred in the structure. One of these deteriorations is the entrance door, which is important in terms of construction technique. The door is made of wooden material, and the künde-kari technique was used in its construction. On the door wings, there are three ten-pointed stars in the vertical direction and internal filling pieces and spine laths derived from these ten-pointed stars. Although the spine

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

laths on the door wings show very different dimensions, the filling pieces consist of deltoids, five-pointed stars, hexagons, and new forms formed by the cuts on the edges of these pieces. There are also metal accessories on the door wings. These metal accessories are used as locks and knockers.

The kundekari door of the Diyarbakır Behram Pasha Mosque has missing pieces due to fragmentation. Since the door was made with the Kundekari construction technique, the missing pieces reveal the possibility of the door falling apart. The door wings are missing, both in the filling pieces and the spine laths. The missing parts on the door are not limited to wooden parts. There are also deficiencies in the metal accessories on the door. In this context, a proposal to integrate the door was developed in the study. In the study, a drawing of the door was made by taking the measurements of the door and photographing it. Depending on these drawings, missing parts in both wooden sections and metal accessory sections were identified and drawn. In this context, it is important to complete the door in line with the drawings made in the study in order to protect and transfer the wooden entrance door of Diyarbakır Behram Pasha Mosque, a work of Mimar Sinan, built with the kündekari construction technique, to the future. Since the door wings were constructed with the real kündekari technique, nails, etc. were not used in the joining of the parts, but it is seen that nails were added later to prevent disintegration from the parts with missing parts. These nails need to be removed during the integration. In addition to the integration of the missing parts in the wood on the door wings, other deterioration in the wood should be detected and removed; harmful insects in the wood should be removed. At the same time, the removal of rust on metal accessories is also important for the protection of the door.

ABSTRACT

With the increase in population in cities, there is a need for new residential areas in urban areas, and in order to meet this need, the use of open-green areas in cities is one of the biggest reasons for micro-scale climate change in cities. Increasing building density creates a heat island in cities and has negative effects on the urban thermal environment. Changes in urban microclimatic conditions have negative effects on the health of urban residents. Increasing health problems lead people to take into consideration factors such as ecological balance, urban comfort, proximity to nature and clean environment, which were not considered important in the past, when determining their living places. Another factor that has gained importance recently is "Thermal comfort". Thermal comfort; These are urban climate conditions where people feel healthier, happier and more dynamic. When the thermal comfort value is within appropriate ranges, people feel healthier, happier and more peaceful. In this context, when creating new living spaces for people, it is necessary to design and plan by taking into account the comfort values of the place. Therefore, in recent years, thermal comfort has become one of the issues that need to be taken into consideration in urban landscape planning studies. In this context, suggestions are made in the study about the importance of thermal comfort, environmental factors affecting thermal comfort in cities, points to be considered in thermal comfort-oriented urban design and planning with different climate types. These suggestions can make a significant contribution to the creation of sustainable cities.

Keywords: Urban Heat Island, Urban Climate, Thermal Comfort, Urban Planning, Urban Design.

1. INTRODUCTION

The factors affecting the establishment of the first permanent settlements of humankind in the world have been subject to many changes until today. It is known that in the early days, the feeling of solidarity was effective in resisting external attacks and fighting against nature. Thus, settlement models have emerged where people live together more in order to resist dangers. agriculture and later the industrial revolution, which greatly influenced human history, played a major role in the establishment of cities. After the agricultural revolution, when cities were established, geographies with a more suitable climate for agriculture and with sufficient rainfall were preferred. The first settlements established in these geographies were in the form of models called simpler village settlements. With the Industrial Revolution, cities developed

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

rapidly and gained a new form, and the population in these places increased more than ever before and continues to increase today. With the increasing need for housing with the industrial revolution, urban areas began to be needed for different uses. To meet these needs as soon as possible, an unplanned, un-programmed, and rapid urbanization process has begun. Due to this unplanned and un-programmed urbanization, natural green areas have been destroyed and the density of dysfunctional buildings in these areas has increased, ignoring the benefits they provide to the world and people. In addition, the change in the morphological structure of the urban fabric the decrease in vegetative surfaces, and the increase in hard surfaces pave the way for the formation of negative microclimatic conditions, causing significant environmental problems in cities. As a result, people living in cities that grow uncontrollably are faced with cities whose functions decrease and pose problems for human health. To reduce the problems caused by unplanned urbanization; Some terms such as ecological balance, clean environment, and comfort conditions are taken into consideration by planning experts. With the increasing income level, these factors come to the fore and are seen as the most important factors in planning the cities where people will live. Based on this, we will focus on the thermal comfort factor, which is effective in carrying out recreational activities in Anatolian cities, and the issues that need to be taken into consideration in urban planning and design.

a. The Importance of Thermal Comfort in Urban Planning and Design

In many developed and developing countries, rapid urbanization and cities that are far from ecological concerns and shaped without any planning have caused individuals to be faced with cities that are far from comfortable and useless. Recently, the number of people living per unit area in cities has increased. As a result, cities became crowded and gloomy structures formed in the focal points of the cities. In these areas, there are many thermal stress factors such as air temperature, humidity and wind currents resulting from excessive construction, which affect human productivity and human health and are environmental problems (Sevik and Belkayali, 2012; Topay and Parladir, 2015).

People living in urban areas where these thermal stress factors are highly exposed feel uneasy and move away from these areas or create their own solutions to live more comfortably there. However, the solutions people produce often harm the environment. For example, the energy used inside buildings for heating or cooling is one of the most important causes of environmental pollution. However, in recent studies on this subject, it has been determined that open spaces have a positive effect on the city's microclimatic conditions, that is, thermal comfort levels (Nikolopoulou et al. 2001). In order to prevent people from finding solutions on their own, thermal comfort-sensitive planning should be made in order to increase the thermal comfort level and prevent environmental problems. Landscape Architects have a great responsibility in thermal comfort-sensitive planning.

b. Thermal Comfort Focused Urban Design in Cities and Aspects to Consider in Urban Planning

One of the most important points to consider in thermal comfort-sensitive planning in cities is the urban climate. When the relationship between climate and planning is mentioned, the situation that comes to mind should be improving the quality of life in outdoor spaces. Some recent studies reveal that thermal environmental factors such as outdoor air temperature, wind speed, relative humidity and solar radiation affect the thermal comfort, perception and therefore satisfaction levels of individuals living in these areas (Alpay et al., 2013). Most people feel

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

comfortable in the temperature range of 20-25.5 °C and 30-60% relative humidity (İlten et al., 2017). Therefore, in order for people to be comfortable in their environment, they must be within a certain temperature, wind and humidity range. This range is called the comfort zone (Boz, 2017). Although there are different climate types exhibited in the world, the comfort range is always the same. In order to achieve this comfort range, plans and designs are made according to each region and each climate type. According to the monthly and annual temperatures and amount of precipitation, the distribution of precipitation throughout the year, and the relationship between precipitation and temperature and natural vegetation, the letter system was used to determine Köppen-Geiger climate types and the climates were grouped into 5 main types (Erlat, 2014; Türkeş, 2010). (Figure 1.). According to the Köppen Climate Classification, B, C and D type climates are observed in Turkey (Peel et al., 2007). (B) type climate; It is seen in the inner parts of Turkey and a part of Southeastern Anatolia, and its most distinctive feature is that it is far from water sources such as seas and lakes and is dominated by dry hot summers and dry cold winters. (C) type climate; It covers the coastal areas and most of Southeastern Anatolia and exhibits a mid-latitude climate with mild humid winters.

In (D) type climate; It is the second climate type with the largest impact area in the world and has cold winters. It generally exhibits continental climate characteristics (Peel et al., 2007). In cities with different climate characteristics, it is necessary to determine local-specific design criteria in order to ensure thermal comfort. These criteria should be climate-sensitive, that is, they should be aimed at protecting urban residents from extremely hot or cold air and surface temperatures, humidity rates and wind currents that will negatively affect thermal comfort.

Tablo 1. Characteristics of basic climate types according to the Köppen-Geiger climate classification (Peel vd., 2007) Table Description: T: Annual Average Temperature, P: Total Annual Precipitation

Harf	Tanım	Temel özelliği
A	Nemli tropikal	Kış mevsiminin yok ve tüm ayların ortalama sıcaklığı 18°C'nin üstündedir. $T_{min} \geq +18^{\circ}\text{C}$
B	Kurak	Buharlaşma yağıştan fazladır ve sürekli su eksikliği vardır $P_{yillik} < 10 \times P_{eşik}$
C	Kışları ılıman nemli orta enlem	En soğuk ayın ortalama sıcaklığının 18°C'nin altında ve 0°C'nin üstünde, en sıcak ayın ortalama sıcaklığı 10°C'nin üstündedir $T_{maks} > 10^{\circ}\text{C}$ ve $0^{\circ}\text{C} < T_{min} < +18^{\circ}\text{C}$
D	Kışları soğuk nemli orta enlem (Karasal iklim)	En soğuk ayın ortalama sıcaklığı 0°C'ye eşit veya altındadır ve en sıcak ayın ortalama sıcaklığı 10°C'nin üstündedir $T_{maks} > 10^{\circ}\text{C}$ ve $T_{min} \leq 0^{\circ}\text{C}$
E	Polar	Yaz mevsimi yoktur ve en sıcak ayın ortalama sıcaklığı 10°C'nin altındadır. $T_{maks} < +10^{\circ}\text{C}$

In the study, suggestions were made on what to pay attention to in planning and design in order to improve thermal comfort in the climate types exhibited in Turkey, and suggested designs were developed by using the same space plane for these climate types. Climate types exhibited in Turkey;

(B) Arid climate zone: In this climate region, which is seen in the inner parts of Turkey and a part of the Southeastern Anatolia Region and where the continental climate prevails, it is similar to the desert climate due to the high temperature differences during the year and day. The

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

summers are very hot and the winters are very cold. is mentioned (Dizdar, 2009). It should be known that, as in every climate zone, there are summer and winter months in these climate zones, and accordingly, planning and design should be made considering the 4 seasons.

- In this context, while making a design suitable for thermal comfort in the arid climate region;
- In cities with an arid climate, surface and air temperatures should be reduced during the summer months and the humidity rate should be increased by exposing urban residents to less solar radiation.
- In order to increase air circulation in these climatic regions, buildings should be designed in a separate order, with different heights and widths so that they do not block each other's wind flow (Chan et al., 2003).
- In order to be protected from the negative effects of the sun, care should be taken to ensure that the plantings in these places have shade and cooling properties. For this purpose, deciduous, densely leafed and large-diameter trees should be included in the summer months in order to both reflect some of the sunlight reaching the place and provide shading at street level and low parts of building facades (Gaitani et al., 2007; Lin, 2009).
- In order to prevent excessive heat increases that may occur indoors and outdoors during the summer months, the east, west and south facades of the buildings surrounding the space should be surrounded by broad-leaved trees and tall shrubs or materials with low heat storage capacity. In addition, building facades and floors should also be planted. For the winter months, the opposite should be done.
- To increase humidity values in these climate zones; It is necessary to plant plants that will increase the humidity level at street level, on building facades and roofs. In addition, water surfaces can be used in spaces to increase the humidity level.
- In order to maintain humidity values, the sky visibility of the space should be increased without ignoring sun exposure (Johansson and Emmanuel, 2006).
- Since they have a cooling effect on water surfaces and affect the humidity in the environment, their use should be increased in summer months and the use of these items should be avoided in winter months (Gaitani et al., 2007; Xu et al., 2010).
- These elements should be designed in the direction of the prevailing wind in order to benefit more from the cooling effect of water surfaces during the hot period. Establishing this relationship should be avoided for the cold period (Yu and Hien, 2006).
- If it is present in hot climate regions, flows coming from areas with water surfaces such as seas and lakes should be provided to reach the space (Johansson and Emmanuel, 2006).
- Urban canyons should be oriented on east-west or similar axes to benefit more from sunlight during the winter months. During the summer months, canyons extending on north-south and similar axes should be designed (Toudert and Mayer, 2004; Johansson and Emmanuel, 2006; Toudert and Mayer, 2007).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

- It is important to increase the surface and air temperatures of the place during the winter months and to ensure that urban residents have access to more sunlight. In addition, air flows that will cause discomfort by causing cooling both in the space and on the human body should be restricted. For this purpose, urban canyons should be oriented as parallel as possible to the dominant wind flow (Georgakis and Santamouris, 2006; Johansson and Emmanuel, 2006).
- The use of green surfaces and permeable surfaces that will absorb water at street level should be increased.
- Materials with high reflectance values should be preferred on building facades and floor coverings in order to prevent the storage of incoming sunlight in areas with arid climate characteristics. In the study, a design was developed for the summer months of arid climate regions in order to be a recommendation.

These climatic regions experience dry summer months, and people who spend time here feel uncomfortable due to conditions such as low humidity and excessive exposure to sunlight. In the draft developed to prevent these problems (Figure 2);

- Buildings were planned far from each other to avoid obstructing wind currents.
- It was used inside the space to benefit from the cooling properties of water surfaces. At the same time, the water surfaces were planned parallel to the prevailing wind direction to provide more cooling properties.
- In order to be protected from sunlight during the summer months, plants with broad leaves and high shading function were used in the space.
- Green surfaces that provide water absorption were used on the street surface.
- Roof gardens and water surfaces were used on building roofs to increase the humidity level.
- In order to increase the humidity value, species that increase the humidity value of the plant species used on the roofs and inside the space were used.
- Spaced broad-leaved trees and shrubs were used to ensure the distribution of wind movements within the space.
- In order to prevent sunlight from being stored in the area, materials with high reflectance values were used on building facades and floor coverings.
- In order to prevent overheating in both exterior and interior spaces during hot periods, it was planned to have broad leaves in front of the western and southern facades of the buildings surrounding the space.

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Figure 2. A design example that increases the thermal comfort level for summer in type B climate zones

C- Temperate-humid climate zone: It is seen in the Black Sea and Marmara regions, where there are large water bodies such as seaside or lakes and rivers that increase the humidity in summer and winter. These are regions where temperature differences between day and night are small, summers are mild and winters are cool, and the amount of precipitation and humidity is high. In order to ensure the thermal comfort of people living in these regions, attention should be paid to reducing surface and air temperatures during the summer months and ensuring appropriate air circulation in the design of spaces. During the winter months, arrangements should be made to provide sunbathing opportunities and reduce wind current. Since the amount of humidity has a great impact on thermal comfort in this climate type, care should be taken to reduce humidity levels in every season.

In this context; while planning and designing in accordance with thermal comfort in the temperate-humid climate region;

- The height/width ratio of urban canyons should be designed at a rate (lower than two) that will not hinder the prevailing wind flow in order to keep the amount of humidity at comfortable levels in all seasons (Johansson and Emmanuel, 2006).
- In order to distribute the existing humidity in the air and prevent its excessive increase, the space should be oriented parallel to the prevailing wind in summer and winter months, and the use of plants that will increase evaporation in the space should be avoided (Johansson and Emmanuel, 2006).
- In order to reduce the amount of moisture, natural green surfaces or permeable surface coatings that will not hinder the absorption of water at street level should be used (Kottmeier et al., 2007).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

- In order to prevent users from feeling uncomfortable due to excessive humidity increase, the use of water surfaces in the space should be avoided at all times (Gober et al., 2010).
- Residences are positioned so as not to interfere with each other's sunlight, air movement and solar radiation.

The biggest problem of this climate zone is that the humidity is high and therefore people living here feel hotter than the current temperature. In this case, it causes the people living here to feel uncomfortable. In the draft developed to prevent these problems (Figure 3);

- The canyons within the venue are planned to be less than 2 meters high in order not to hinder wind movement.
- Since humidity is a big problem here, the place was planned parallel to the prevailing wind in order to disperse the existing humidity.
- Again, in order to reduce the humidity factor, the plant species used in the space should not increase evaporation and permeable materials were used with plant surfaces that allow the absorption of water at street level.
- In order to prevent increased humidity, water surfaces were not used in the space.
- Finally, it was designed to ensure that there is sufficient distance between the residences so that they do not block each other's wind and sunlight.

Figure 3. A design example that increases the thermal comfort level for the summer season in type C climate zones

D- Continental (Cold) Climate Zone: These are regions where the temperature difference between summer and winter and night and day is high, and precipitation generally occurs in spring and winter. In this climate type, the vegetation that usually blooms in spring dries out during the dry summer months and takes on a steppe appearance. The dominant season of these regions is winter because winter comes very early to these regions and the most precipitation is in the form of snow. In order to ensure the thermal comfort of urban residents in these regions, it is necessary to reduce surface and air temperatures in summer, reduce humidity and ensure proper air circulation within the space. During the winter months, the surface and air temperatures of the place should be increased, urban residents should be provided with more

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

sunlight, and wind currents that may cause people to feel uncomfortable should be restricted and the humidity rate should be reduced. Although it is called a cold climate region, it should be taken into consideration that summer months are also experienced in these regions. In this regard, winter and summer months should be considered when making design decisions. Of course, since the winter months are longer, this should also be taken into consideration in decisions.

In this context, when designing for thermal comfort in the continental climate region;

- South should be preferred as the orientation direction.
- Water surfaces have a cooling effect in the place where they are used. Due to the harsh winter months, the use of water surfaces that will increase the cooling effect in outdoor areas should be avoided.
- The dominant wind direction should be determined and planting should be done to reduce the effect of the wind. High-tall coniferous trees should be planted in the first row, preferably by adopting the staggering method. In the planting works to be carried out in the north-west direction, coniferous vegetation should be used more intensively to block the wind, and the southern direction should be left open or deciduous plants should be used to ensure the passage of sunlight that will warm the region during the winter months.
- In order to restrict air circulation in cold climate regions, the surrounding buildings should be adjacent to each other and have close heights and floor areas (Chan et al., 2001; Chan et al., 2003).
- Urban canyons should be oriented as perpendicular as possible to the prevailing wind flow (Johansson and Emmanuel, 2006).
- Wind currents disturb people and reduce their comfort level. Especially in the winter months, this level of discomfort increases even more. In order to prevent this, the gaps where the prevailing wind comes should be identified and passages or plants and street furniture should be used to prevent this wind flow from affecting the users.
- In order to store the sun rays during the winter months and make the evenings warmer, care should be taken to choose dark colored floor coverings used outdoors to have more heat retention.
- In order for people living in these climate zones to increase their use of outdoor spaces during the summer months, solutions should be provided to increase the humidity level. For example, plantings that increase the humidity effect can be made at street level.
- Deciduous, densely leafed and large-diameter trees should be used in order to reflect some of the sunlight coming into the place during the summer months and to provide shading at the street level and in the low parts of the building facades. If artificial materials are to be used, care should be taken to ensure that these materials have low heat storage capacity and high reflectivity. The use of these materials should be avoided during winter months (Toudert and Mayer, 2004).
- If it is present in cold climate regions, the access of flows coming from areas with water surfaces such as seas and lakes into the space should be restricted. In the hot period, blocking the access of these flows should be avoided (Johansson and Emmanuel, 2006).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

The biggest problem of this climate region is the high temperature differences between day and night and the high number of cold days. For this reason, people living here feel uncomfortable with cold weather conditions and wind movements that cause cold weather conditions to be felt more. In the draft developed to prevent these problems (Figure 4);

- Wind movements were restricted by considering planting in the form of screening in the direction of the prevailing wind.
- It was thought that people could benefit from sunlight in winter by using deciduous plants in the east and west directions.
- By positioning the buildings vertically to block the prevailing wind, wind movements are prevented from reaching the interior areas.
- In addition, planting was done between the buildings to prevent wind movements that may come between the buildings.
- In order to absorb the sun's rays and make the nights warmer, dark colored coatings and floors that absorb the sun's rays were used on the building facades, roofs and floors.
- Since water surfaces have a cooling effect, they were not considered to be used in this design.

Figure 4. A design example that increases the thermal comfort level for the winter season of D type climate zones

Apart from these, the points to be taken into consideration when planning and designing in accordance with thermal comfort in urban spaces in all climatic regions are;

- Establishing new residential areas in comfortable areas in terms of thermal comfort will significantly save the energy that will be spent to transform uncomfortable areas into comfortable areas. For this reason, it is recommended to use comfortable areas to create comfort maps of the region before planning new residential areas (Alpay et al., 2013; Çalı, 2018).
- In order to prevent heat islands, which have a great impact on thermal discomfort, hard floors should be reduced and permeable surfaces should be created or green areas should be increased to prevent the temperature increase in urban areas. Additionally, the use of vertical gardens and roof gardens should be increased.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

- In regions where the urban heat island is very high, light-colored materials should be used to reflect the sun's rays.
- Sky visibility should be reduced by increasing planting efforts in the city, and overheating at street level should be prevented by the shading function of trees.

2. CONCLUSION and RECOMMENDATIONS

Thermal comfort is an element that should be taken into consideration in today's city planning. Planning and designs made in cities by taking thermal comfort into consideration are for the citizens to live more comfortably and healthier. Planners and designers, that is, us, have a great responsibility in ensuring this. The most important point that planners and designers should know is that each living space has its own specific climatic conditions and that the climate factor must be taken into account first in the planning to be made. In addition, the identity and natural structure of the city should also be taken into consideration. It should not be forgotten that when wrong planning and design decisions are made, it causes the formation of urban heat islands, which is one of the reasons why people feel uneasy. More attention should be paid to the points mentioned above to prevent the creation of areas that are not suitable for comfort, which increases the level of dissatisfaction among urban residents.

As a result of Turkey's geographical location and landforms, it has many complex climate types. Due to Turkey's complex climate types, cities will be negatively affected, especially due to global warming. In order to reduce this effect, designing urban green areas with urban comfort in mind will increase the living comfort of the city.

ABSTRACT

One of the biggest causes of global climate change is the rapidly growing cities in order to meet the increasing population. Due to urban sprawl and increasing automobile use in these cities; carbon footprint increases, agricultural and forest areas are destroyed, water resources, natural environment and air are polluted. This causes irreversible climate disasters. In order to learn from climate disasters and to take precautions against new disasters, studies are carried out in the context of "sustainable cities and societies" from the individual level to the national level. "Walkability" is a basic concept for ensuring sustainability in cities. Walkability is a concept that has gained importance especially with the recent Covid-19 pandemic in order to prevent the negative effects of urban sprawl, suburbanization, expanding road network and increasing vehicle ownership in cities and to provide a "pedestrian-oriented design" approach in cities. During the pandemic period, the importance of walking at every walkable distance and the necessity of designing compact cities that can be walked within 15 minutes have emerged. University campuses with the characteristics of a small compact city; it combines different functions such as work, accommodation, recreation, education, health and sports areas. Therefore, people of various profiles spend time in these areas during the day, participate in different actions and activities, and pedestrian mobility occurs within the campus. For this reason, it is important to investigate the walkability on campus campuses. In this study, it is aimed to explain that sustainable urban life can be achieved with walkability in university campuses, which are small compact living spaces with common areas.

Keywords: Sustainability, Walkability, University Campus, Accessibility, Climate Change.

1. INTRODUCTION

Uncontrolled growing cities, at the expense of destroying green areas, agricultural and forest areas in order to quickly solve the housing problem in increasingly crowded cities, is one of the biggest causes of global climate change. The change in consumption styles compared to the past, such as people's tendency to use individual vehicles, also increases the rate of environmental pollution in cities. These changing consumption patterns not only cause air pollution or health problems, but also cause the world community to face new problems such as global climate change due to the increase in carbon footprint. The main reason for these problems is that people think that the natural environment and resources in the world are infinite, and the way they live their lives uses these natural resources in an unsustainable way.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

After many years of unconscious use of resources, societies have realized that these resources in the world are limited. As a result, the Brundtland (Our Common Future) Report (1987) and the subsequent Rio Summit and Agenda 21 (1992), the UN Conference on Human Settlements-Habitat II (1996) introduced the 'sustainable development' approach, the UN Millennium Summit (2010), Rio A sustainability approach that balances the protection of the natural environment and ensuring social development was also proposed at the +20 Summit (2012) conferences (Anonymous, 2012a).

In order to cope with the poverty, inequality, disease, hunger and climate change that people face today, the United Nations Sustainable Development Conference was held in 2012 and measures aimed at sustainable development were determined. The "Future We Want" document, signed by 193 member countries of this conference and containing 17 targets to eliminate poverty in the world, protect the world and ensure that people live in prosperity by 2030, came into force in 2016 (Figure 1). The goals included in the document called The Future We Want are; ending hunger, reducing poverty, ensuring a healthy life, eliminating economic inequality, sustainable energy use, sustainable architecture and urbanization, renewable production and consumption, and combating climate change (Anonymous, 2012a).

Figure 1. 17 Goals of sustainable development

In this study, the "Sustainable Cities and Communities" target, which is the 11th of the 17 goals of sustainable development, will be examined. Within the scope of this purpose, the points that need to be taken into consideration in urban planning to ensure sustainability in cities will be emphasized. In order to develop the understanding of sustainability in cities, the environmental, social and economic dimensions of sustainability must be addressed together and a holistic approach is required.

Environmental dimension of sustainability;

Environmental issues that need to be addressed in terms of sustainability are resource use, energy, water, waste, urban nature and environmental justice (Grove, 2009). Resource use is

TeMALab
 Department of Civil, Building and Environmental Engineering
 University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

the first dimension of environmental sustainability (Nijkamp and Opschoor), and the sustainability of resources depends on the sustainability of the city's production and consumption processes. In order to ensure environmental sustainability, attention will be paid to issues that will support the preservation of balance in nature, such as protecting biodiversity, using renewable resources, using environmentally friendly technologies with a zero waste and emission target, and supplying environmentally friendly products.

The basic principles of environmental sustainability can be listed as follows

Table 1. Environmental sustainability criteria (Moldan vd., 2012):

Environmental Sustainability Criteria	
Effective use of climate data	Climate data should be used in the planning and design of campuses in a way that will save energy.
Using non-renewable resources efficiently	Natural resources such as existing vegetation, streams, flora and fauna should be protected and used.
Energy and Waste Recovery	The use of renewable energy sources should be prioritized. Wastes such as paper, metal and glass should be separated on site and recycled and put into use. (Atıl, Gülgün and Yörük, 2005).
Effective Use of Topographic Data	Infrastructure and superstructure problems arising from the land should be minimized. In addition, erosion controls should be carried out, the land structure should be protected, a good planning should be made to meet the needs of all the structures to be built, pedestrians, all vehicle users and cyclists should be considered by paying attention to the adequacy of transportation routes within the land, the land habitat should be protected, a suitable environment should be created for the cultivation of natural species, and finally Control and use of water coming from rainfall should be ensured.
Use of Natural Vegetation	Expenses such as irrigation, disinfection and maintenance should be reduced by paying attention to the use of natural species of the region in the planting works to be carried out in the area.

Economic dimension of sustainability;

In order to ensure economic sustainability, it is possible to ensure that the services provided to the society are based on nature protection, that the continuity of goods and services is ensured, and that resource efficiency is within natural limits (Yazar, 2006). To put it more clearly, renewable energy should be used, recycling and recovery principles should be adopted, public transport-oriented transportation should be increased, and ecology-based production should be expanded.

An ideal and sustainable economy is one that provides the highest amount of general welfare by using the least amount of resources and ensuring the lowest level of environmental damage. To be truly economically sustainable, the overall demand for natural resources must be less than nature's supply of renewable resources (Anonymous, 2023).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Social dimension of sustainability;

Sustainability represents a social ideal as well as a concrete goal in terms of physical structure (Whitehead, 2003). Socially sustainable basically refers to projects that support the development of society by contributing to it. In this context, it can be observed that in a socially sustainable city, the quality of life is high, there are no discriminations, there is high human interaction and cultural development (Bramley and Power, 2009). In order to ensure social sustainability;

- Ensuring social integration,
- Health
- Access to public green areas and services,
- Nutrition,
- Sufficient housing stock,
- Transport,
- Education,
- Cultural services

are individual needs that must be met (Moldan et al., 2012)

It is seen that the environmental, economic and social dimensions of sustainability mentioned above are related to the subheadings of the "Sustainable Cities and Communities" target, which is the 11th goal of the "Future We Want" document. When we look at these related subheadings, we look at accommodating the increasing population, designing urban transformation in a renewable and environmentally friendly way, reducing environmental impacts in cities, reducing the negative effects of natural disasters, providing access to these areas by including more green and public areas in designs, resource efficiency and It can be seen that issues that will help develop the concept of sustainable cities by implementing policies to reduce disaster risk and protecting the world's cultural and natural heritage are discussed (Figure 2).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Figure 2. Goal 11 of sustainable development (Anonymous, 2012a)

The 11th goal of Sustainable Development is based on making residential areas inclusive, safe, durable and sustainable. In fact, cities and people are at the center of these goals. The biggest action that brings cities and people together is walking. Walking is a form of transportation that people use to meet their daily needs, go to work, school or parks, reach their destination or go to public transportation stops for a long-distance journey. This form of transportation is a part of our daily life, and when the physical environment allows walking, it creates walkable environments. The main purpose of walkable environments is to encourage people to walk and thus ensure sustainability in cities.

Walking and walkability are most important for the sustainability of natural and environmental resources. Walking is a clean form of transportation and helps reduce air pollution. In addition, the use of walking as a form of transportation enables cities to move away from the automobile-dependent setup (Yazıcıoğlu Halu, 2010). Thus, energy consumption, fossil fuel use, air pollution and carbon emissions in cities are reduced. Additionally, distances between destinations are close due to the compact design in a walkable environment. Having residences, workplaces, shopping, schools and entertainment areas close to each other prevents urban sprawl and sprawl; It prevents the destruction of fertile agricultural lands, wetlands and forest areas. The basis of all these environmental benefits is the increase in walkability and the resulting change in the urban development model (compact urban development model). For this reason, improving walkability is directly and indirectly beneficial in combating climate change.

Walkability also ensures economic sustainability as it creates pedestrian mobility and increases the efficiency of commercial activity. Since walking is a cheap form of transportation, it provides economic benefits for the individual. In addition, the time spent in walkable environments increases and therefore the money spent increases; Thus, the efficiency of urban commercial activities increases.

Walkability is a socially fair means of transportation that does not create class discrimination because it is open to the whole society (Forsyth & Southworth, 2008). In this respect,

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

walkability has public benefits such as ensuring social justice and eliminating social segregation. Walkability enables citizens to be included in urban life and at the same time provides many social benefits to the city.

Walkable environments are important for the sustainability of human health, the natural environment, the global economy and social structure. Walking is beneficial for the physical and mental health of individual people. The sustainability of walkability on human health emerges here. It has been scientifically proven that people who make walking a form of transportation and walk regularly are less exposed to chronic diseases such as obesity, hypertension, diabetes, cardiovascular disease and depression. It is also known that as walking and walkability increases, individual vehicle use and therefore air pollution decrease. Thus, the incidence of respiratory system disorders such as asthma caused by air pollution also decreases.

The issue of walkability has been brought to the agenda in terms of individual health during the Covid-19 epidemic and its importance has been re-understood. In this process, people spent time in public spaces where they could feel safe in terms of health, paying attention to both social distance and hygiene conditions. Additionally, individual modes of transportation were preferred to maintain social distance during this process. During this period, private vehicles were used for long distances as a mode of individual transportation; In close distances, transportation is possible on foot or by bicycle. For this reason, in this process, in order to increase walking and reduce carbon emissions, the concepts of "pedestrian-oriented design", "walkable cities" and "15-minute cities" have come to the fore and exemplary cities have been designed. One of these cities is Melbourne.

According to the target set for the city of Melbourne, each neighborhood will be able to reach all the units it needs within 800 meters, that is, a 20-minute walk. To achieve this goal; providing safe, accessible and well-connected spaces for pedestrians and cyclists, providing high-quality public spaces and open spaces, providing services and destinations that support local life, facilitating access to public transport connecting people to urban services, providing housing/population at appropriate densities that make local services and transport viable and strategies such as supporting developing local economies have been developed (The State of Victoria Department of Environment, Land, Water and Planning, 2019). In addition to Melbourne, many cities such as Paris and Shanghai have adopted the 15-minute city concept. In 15-minute neighborhood units, it is aimed to design many functions in people's daily lives, such as housing, education, health, work, shopping, entertainment and green areas, together and to be located within walkable distances.

At the heart of such walkable cities is a pedestrian-oriented urban design approach, and in this approach, priority is given to pedestrians and pedestrian areas. This approach includes many goals that separate pedestrians from vehicle traffic, encourage them to walk at walkable distances, and enable pedestrians to use public spaces not only to meet their essential needs but also to socialize and spend time. Another goal of the pedestrian-oriented design approach is the integration of pedestrian access networks with different transportation modes (tram, bicycle, bus, etc.). Thus, when the pedestrian wants to reach long distances, he will be able to find many modes of transportation that he can easily access and use on his own route.

In walkable cities, pedestrian spaces must meet walkable environmental criteria. Walkability is the degree to which the built environment supports and encourages walking by providing pedestrian comfort and safety, connecting people within a reasonable amount of time and effort,

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

and providing visual interest during the journey through the network (Southworth, 2005). As can be understood from this definition, walkability depends on the physical characteristics of the built environment. These qualities determine the walking demand for pedestrian space by affecting pedestrians' perception and walking preference. There are various definitions for these qualities by different authors. A literature review about the physical characteristics that a walkable environment should have is given below.

According to Dovey and Pafka (2020), the realization of walkability in urban space depends on DMA, that is; It depends on density, functional mix and access. Densities of buildings and people, the mix of different functions and attractions (places of interest), and the access networks we use to navigate between them are the basic tools of walkability.

In 2005, Alfonzo conducted a study in which he revealed the factors affecting walking behavior and the parameters affecting a person's decision to walk, and based on this study, he created a walking needs hierarchy model. This model suggests that there are five levels of needs that relate to urban form and are taken into account in walking decision-making. These; feasibility, accessibility, safety, comfort and pleasurability. There is no dominant need in this five-step hierarchy of needs created by Alfonzo, but each need is directly linked to the previous and next steps.

Another study to define a walkable environment was conducted by Ann Forsyth. Forsyth (2015) generally associates walkability with the physical environment and argues that a walkable environment should have four basic qualities: passable, compact, safe and physically attractive.

As mentioned above, these physical qualities can be questioned in settlements where there are campuses, neighborhoods, public spaces, pedestrian areas and mixed use of land within a 15-20 minute walking distance (within an average distance of 500-800 meters). At this point, university campuses, which are found in almost every city in our country, appear as small city models. University campuses host many different units and various social, cultural and sports activities within their large areas; ensuring integrity between buildings and open spaces; Since they have versatile functions such as allowing space use with outdoor arrangements, they form small city models in themselves. For this reason, the sustainability of university campuses through walkability will be discussed within the scope of the study.

2. DISCUSSION and SUGGESTIONS

According to the literature review, the "Sustainable Cities and Communities" target, one of the 17 Sustainable Development Goals; It includes studies that focus on humans. In this pyramid, whose cornerstone is people, individual, social and global changes can occur respectively. In other words, when individual sustainability is achieved, societies and cities develop and become sustainable. In order to increase individual sustainability, people should actually be on foot and walking in cities; It directly affects the physical, social, cultural and community life of cities. In this respect, it is important to investigate this effect in certain urban areas within cities. University campuses, which are a part of cities and contribute to the scientific development of the society, are important living spaces that need to be addressed in terms of sustainability and walkability.

Apart from the basic functions of education and research, universities also provide services as required by today's conditions; working, accommodation, eating, drinking, shopping, entertainment, sports, recreation, health, etc. They are campuses that have physical qualities to

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

meet many functions (Büyükşahin Sıramkaya & Çınar, 2012). In these campuses, there are planning criteria for common use spaces where staff and students from all institutions in the university can come together and exchange ideas. One of these criteria is to associate these functions mentioned above, create a systematic order and ensure that they work as a whole. At this point, the urbanism principles of walkability and sustainability need to be addressed in a holistic manner.

3. CONCLUSION and RECOMMENDATIONS

Achieving urban sustainability in university campuses is possible based on walkability and criteria. According to the literature review, for a campus to be walkable; first of all, it must be passable or walking action is possible. In other words, pedestrians should be able to reach the destinations they want to reach within the campus by walking, and the path should be suitable for walking. For this purpose, activities and units within the campus must be within walking distance of the residences or dormitories where pedestrians live, and the walking path must be allocated to pedestrians. Thus, every activity within a walkable distance encourages walking and contributes to the reduction of private vehicle use and therefore carbon emissions.

Secondly, in order for the campuses to be walkable, the campuses are compact; In other words, the functions within the campus should be intense and diverse. Since university campuses are developed within areas with certain boundaries, they are prone to the compact development model. And according to this development model, functions within campuses should generally be diverse and intense. Faculties, residences, sports complexes, health units and markets within the campuses should be designed close to each other and at walkable distances. Thus, pedestrians will be able to meet all their needs in areas close to each other and choose to walk to every destination they want to reach. Thus, urban sprawl will be prevented and the damage to nature and the damage caused to the environment due to the use of private vehicles will be reduced.

Another criterion for campuses to be walkable is physical accessibility. For this reason, human scale and pedestrians should be the priority within the campus. When pedestrians are mentioned, people walking may come to mind; However, disabled individuals and disadvantaged groups such as the elderly, children, etc. everyone should be considered on foot. For this reason, there should be special paths for every pedestrian within the campus; Pedestrian and vehicle traffic should be separated and, if possible, bicycle and public transport paths should be designed separately from private vehicle paths. In addition, all pedestrian access networks for pedestrians must be accessible to every activity and public transportation stops within the campus. Thus, there will be a mode of transportation that can be used by people from all walks of life, and people from all profiles will be able to access the function they need; The campuses will be places with high pedestrian accessibility, accessible by all segments of society and therefore preferred.

Another criterion for walkability is safety. The perception of security in campuses depends on factors such as high illumination at night, eliminating negative physical conditions related to comfort (shade, sun, rain, wind, etc.) and creating areas separated from vehicle traffic. Campuses are public spaces that are used actively throughout the day, thanks to their spatial diversity (Tatal, 2018). In order for these places to be safe, they must be alive at night as well as during the day. For this reason, pedestrians should be encouraged to use these spaces actively throughout the day. To achieve this, campuses must have good night lighting and the number

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

of activities suitable for night use must be high. Thus, social vitality and preferability will be ensured in the campuses.

Another criterion for walkability is comfort and, accordingly, satisfaction. Comfort refers to a person's level of comfort and satisfaction. Comfort criteria depend on many factors such as sun, shade, wind, landscape, climatic conditions, weather, urban design elements that provide protection from adverse or extreme weather conditions, and street furniture that provides convenience in urban spaces. To ensure this, according to Alfonzo (2005), the relationship between pedestrian and vehicle traffic should be balanced; The presence of traffic calming elements, speed limiters and buffers should be auditable; The status of the pedestrian crossing system should be shaped according to the urban form; pavement widths must comply with standards and pavement maintenance must be carried out regularly; Urban design elements such as canopies and passages that provide protection from adverse or extreme weather conditions and street furniture that provide convenience in urban spaces should be designed.

Finally, according to the literature review, it is important that campuses are attractive for walkability and provide visual interest to pedestrians while walking. A place that is physically attractive for this; It must provide a physical infrastructure, including wide and well-maintained sidewalks, lively street frontages, traffic calming measures, street trees and planted buffers, marked and signalized pedestrian crossings, benches, wayfinding signs and pedestrian-scale lighting. Thus, a physically attractive place is interesting, arouses curiosity and encourages people to walk. People walk because they want to see that place, not because they have to.

When the physical walkability criteria mentioned above are met, the walkability and therefore sustainability of university campuses will be ensured. Sustainability is a form of urban intervention that begins in urban areas such as universities or even at the street scale. Although sustainable development goals include upper-scale decisions, they also include decisions based on the street and human scale. In this study, walkability criteria that should be taken into consideration in university campuses, which are a small part of a city, are mentioned and suggestions are made. If university campuses are designed in line with the walkability criteria that should be taken into consideration in urban planning; It will contribute to urban sustainability with these design criteria.

ABSTRACT

Unique memory and local architectural understanding, have been transferred to the present throughout the history and bring the rural architectural heritage to the agenda. In this sense, Sille archaeological and urban site standing out with its historical settlement is noticed with its natural heritage and the historical urban pattern created by its traditional architectural heritage in Konya which is hosted many different civilizations throughout history. In this study, the architectural features of the house numbered 1-3, which is located on Hacı Ali and Nalpınar Streets, the remarkable streets of city of Sille, and dated back to the beginning of the 20th century with its traditional Sille house style and registered style, have been evaluated by focusing on the heritage from the past to the future. Therefore, it is aimed to understand the importance of this vernacular architectural heritage knowledge formed by the preservation of traditional houses by examining it with many parameters such as architectural features, spatial organization, material properties and with the information of its belonging to Hacı Ali Ağa, who gave his name to the street in the south of the house and had this house built for him.

Keywords: Konya/Sille, Traditional Housing, Rural-Vernacular Architecture, Architectural Heritage.

3. INTRODUCTION

Throughout history, humans have formed various living units to meet their basic life requirements such as nutrition and shelter. In the early periods, these living units were often created by utilizing natural elements like caves, but over time, humans developed their construction abilities, transitioning to settled life and starting to construct their own structures tailored to their needs. These structures not only fulfilled the basic needs of humans but also evolved into spaces reflecting their social and cultural needs. Over time, units of life such as streets, squares, and neighborhoods came together in a certain order to form larger settlements, becoming spaces where cultural and architectural connections were established. It can be said

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

that traditional Turkish houses bear traces of these settlements created in this context. Similarly, the use of flat roofs, among other architectural features, in the Çatalhöyük settlement, which dates back 7,500 years in the southeast of Konya province, along with its other similar architectural characteristics and its location on a circulation axis, serves as evidence that these architectural features had an influence in various regions of Anatolia (Kuban, 1995; Bektaş, 1996).

The topography and climatic conditions of Anatolia are among the factors influencing housing design. The stages that affect the architectural character, such as construction techniques, materials used, and facade designs, have been shaped under the influence of the region's geographical and climatic characteristics. Additionally, factors such as the regions economy, culture, and lifestyle have also influenced architectural design. The combination and interaction of all these factors have resulted in different architectural outcomes in various regions of Anatolia. These diverse architectural outcomes have enriched local architecture and added unique value to the regions (Küçükerman, 2007).

The formation of the characteristic features of traditional Turkish houses can be traced back to many years ago, and it is understood that the general characteristics of these houses have evolved over time as a result of accumulated cultural heritage and experiences. In this context, the emerging vernacular heritage, also known as traditional-rural architecture, plays an important role in transferring knowledge from the past to the present, depending on experiences, regions, and needs (Gül, Bostan & Akın, 2019; Canan, Kobya, Aköz & Temizci, 2020).

Within this framework, the concept of preservation emphasizes the need to protect all forms of cultural assets, created by human hands and natural elements, as unique and irreplaceable, in order to pass them on to future generations. This vernacular-rural heritage is seen as an accumulated treasure of knowledge and experience, and it is emphasized that this heritage can be used as a valuable and important resource (Yaldız and Asatekin, 2016).

Traditional Turkish House and Architectural Features

The Traditional Turkish House, with its origins tracing back to Anatolia and subsequently developing distinctive characteristics under the dominion of the Ottoman Empire, represents a house type rooted in a rich historical heritage (Eldem, 1995). The emergence of this architectural tradition was significantly influenced by numerous factors such as climate and geography, leading to variations in the traditional Turkish house concept across different regions of Anatolia (Sezgin, 2006). Cengiz Bektaş (2001) delineates ten fundamental principles that constitute the essence of the Turkish house (Table 1).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Table 1. The principles underlying the turkish house (Bektaş, 2001)

Number	Principles That Form the Traditional Turkish House
1	Suitability for Life, Nature and Environmental Conditions
2	Design Based on Realism, Rationality, Desires and Needs
3	Inside Out Solution
4	Internal-External Harmony
5	Frugality
6	Convenience Principle
7	Sizes Suitable for the Human Body
8	Climate Suitability
9	Choosing the Equipment Closely
10	Flexibility

One of the most distinctive and noteworthy features of the traditional Turkish house's architectural concept is the transformation and integration of rooms with a central space called 'sofa.' Different floor plan schemes can be observed, including those without a central sofa, with external sofas, and with internal central sofas. Traditional Turkish houses are typically constructed as single-story or two-story buildings. In two-story traditional Turkish houses, the lower floor typically consists of service areas or production units such as storage rooms and haylofts, while the upper floor serves as the main living unit. Another striking characteristic of Turkish houses is their design process, which is conceived from the inside out. This design approach aligns with the principle of form following function, as seen in modern architectural movements. Inside traditional Turkish houses, interior features include cabinets used for storage and decorative niches. These elements not only serve functional purposes but also contribute to the visual expression of the spaces through their craftsmanship in woodwork (Eldem, 1995; Uşma & Urfalıoğlu, 2018; Bektaş, 1996; Özcan & Güngör, 2019). (Figure 1).

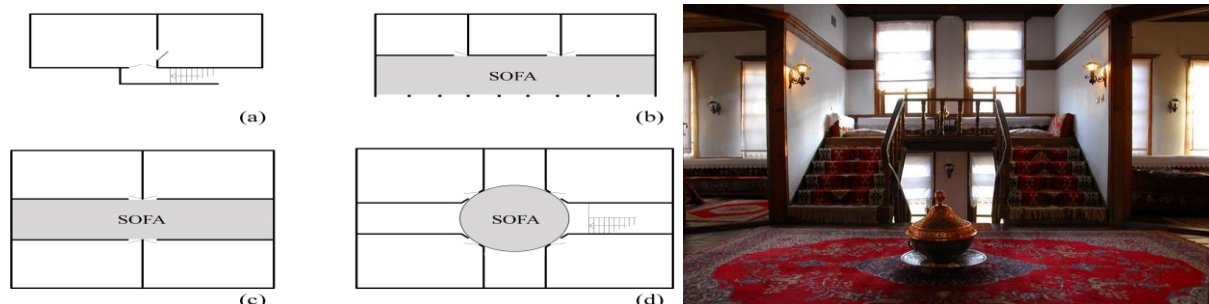

Figure 1. Examples from the traditional Turkish house plan scheme a) Plan type without sofa b) Plan type with outer sofa c) Plan type with inner sofa d) Plan type with middle sofa (According to Sedad Hakkı Eldem) and spaces specialized with the use of sofa (Binay, 2021)

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

In terms of construction techniques, the Traditional Turkish house commonly employs the use of wooden framework infilled with mudbrick or 'bağdadi' construction method. These construction techniques may vary depending on the size and ornamental features of the structures. The primary construction materials in Traditional Turkish houses consist of locally sourced materials such as wood and stone. In regions dominated by the Anatolian steppe, adobe, commonly known as 'kerpiç,' is preferred as a building material (Sezgin, 2006). (Figure 1 and Figure 2).

Figure 2. Examples of Traditional Turkish Houses from different regions are the Kütahya house example (Bektaş, 1996), the Safranbolu house example (Küçükerman, 1985), the Kayseri Erkilet house example (Bektaş, 1996), and the use of materials specific to the region and construction techniques

In the arrangement of facades in traditional Turkish houses, doors and windows play a significant role and are tailored to their environmental context, often featuring prominent wooden doors and windows. Some design solutions exhibit a tendency to open towards the external environment, the street, or the exterior of the building, highlighting the concept of projections that define the facade typology in traditional Turkish houses and establish a connection between the interior dwelling and the outside world. These projections, known as 'cumba' in some regions of Anatolia, are designed to extend the available space by projecting outward, particularly on upper floors (Özcan & Güngör, 2019). (Figure 1 and Figure 2).

4. MATERIALS and METHODS

The scope of this study revolves around contributing to the characterization of the traditional architectural fabric of Sille through the examination of specific parameters, such as land use and orientation, material usage, construction techniques, structural elements, architectural components, facade typology, space organization, and interior features. The study focuses on House No. 1-3, also known as Hacı Ali Ağa Mansion, located on Hacı Ali Ağa Street and Nalpınar Street within the historical center of Sille. This research aims to shed light on the reflection of architectural heritage from the past, emphasizing the importance not only of preserving this heritage but also of utilizing this vernacular architectural legacy.

The methodological framework of this study comprises four distinct phases. In the first phase, the focus was placed on the concepts of rural-traditional heritage and cultural heritage. The second phase involved the architectural definition of the Traditional Turkish House in terms of its functionality and spatial characteristics. The third phase, designated as the 'Findings and Discussion' section, entailed an examination of the study area, Sille town, and its present-day condition. Within this section, attention was directed toward Sille's urban settlement and the traditional residential fabric as a subtopic. In another subheading, the architectural features of Hacı Ali Ağa Mansion were scrutinized within specified parameters. The overarching objective

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

of these stages was to document the vernacular wisdom reflected in the traditional residential architecture of Sille, with the intention of passing it on to future generations. Furthermore, it is envisioned that this study will serve as a foundational reference for future research endeavors.

The literature review section of this study has been meticulously constructed, with a comprehensive approach. To achieve this, an extensive review of resources was conducted, encompassing master's theses, doctoral dissertations, and scholarly articles. Internet-based research methods were employed to gather diverse sources of information. Furthermore, various visuals, periodicals, books, documents, user-generated videos, surveys, and institutional reports were scrutinized in alignment with the objectives of this research. An archival search was conducted specifically for Sille urban settlement, wherein data related to projects, plans, drawings, survey-restoration efforts, preservation initiatives, and analyses, including Conservation-Oriented Zoning Plans, as well as various maps and photographs, were sourced from official institutions. On-site inspections of local examples allowed for direct observation of the surroundings and area analysis. The process was further enriched through on-site photography, contributing to the overall research endeavor.

5. FINDINGS and DISCUSSION

a. Field of Study and Its Current Situation

Within the scope of this study, the historical settlement of Sille, located approximately 10 kilometers from the city center of Konya in the Central Anatolia region of Turkey, was selected as the study area. This choice was made with a consideration of the rapidly changing environmental conditions affecting residential architecture, highlighting the traditional-rural architecture prevalent in the region. (Figure 3 and Figure 4).

Figure 3. Location of Sille city on Turkey map (Google Maps, 2023) **Figure 4.** Location map of Sille city (Google Maps, 2023)

The historical settlement of Sille has been a host to various civilizations throughout history and has emerged as one of the prominent urban areas today, owing to its rich natural heritage and historical fabric. Sille's historical urban settlement, with its amalgamation of traditional memory, urban identity, and regional lifestyle, along with its unique architectural approach, has the potential to transform the region into a focal point. (Kuyrukçu & Kuyrukçu, 2015; Aklanoglu and Erdoğan, 2011).

Due to its historical identity, traditional architectural heritage, cultural and natural riches, the historical settlement and urban fabric of Sille have been deemed worthy of preservation. For this purpose, in 1995, a decision was made by the Konya Cultural and Natural Heritage Protection Board to declare the southern slopes of the old ancient settlement area in Sille as a

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

1st Degree Archaeological Site, while the main settlement area was designated as an Urban Conservation Area. Additionally, in 2001, a Conservation-Oriented Zoning Plan was completed as per the Protection Board's decision (Aklanoğlu and Erdoğan, 2011; Sille Street Rehabilitation Survey Report, 2014). (Figure 5, Figure 6, and Figure 7).

Figure 5. Sille registered buildings map and representation of urban-archaeological protected areas (Çiçek, 2010)

Sille has been designated as both an archaeological and urban conservation area, a decision regarded as a significant step in the context of sustainable tourism. This measure not only contributes to the preservation of the region's cultural and historical treasures but also fosters the development of sustainable tourism activities. (Kuyrukçu & Kuyrukçu, 2015; Aklanoğlu and Erdoğan, 2011; Sille Street Rehabilitation Survey Report, 2014). (Figure 6).

Figure 6. Sille conservation zoning plan (Sille Municipality Culture and Tourism Archive) and **Figure 7.** Sille site impact transition area (Sille (Subaşı) Neighborhood Conservation Implementation Zoning Plan Study 1/1000 Scale Conservation Implementation Zoning Plan Explanation Report, 2022)

Presently, restoration and street rehabilitation projects are being carried out in the historical settlement of Sille in accordance with Law No. 2863 on the Protection of Cultural and Natural Assets. These initiatives aim to maintain a balance between the preservation and utilization of

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Sille, thereby contributing to the promotion and sustainable development of the town. Furthermore, the Sille urban settlement is included in the master plan of Konya Municipality, aligning with efforts to support the future development and organization of Sille (Solak, 2016).

b. Sille Historical City Settlement and Traditional Housing Texture

The settlement area of Sille, distinguished by its rich historical and cultural identity, has been known by various names throughout different periods, owing to its history of coexistence of diverse beliefs and cultures and hosting numerous civilizations. It carries a significant vernacular architectural heritage within its boundaries. This area serves as a bridge between the past and the present, functioning as a micro-level cultural tourism corridor within the Konya province and on a broader scale, as a national and international cultural tourism corridor. (Sönmez, Sadıklar, K. Torun & Torun, 2017; Erdem, Yıldırım, Çiftçi, Dülgerler, Çıbıkdiken, Levend & Erdoğan, 2010). (Figure 8).

Figure 8. View of Sille at the beginning of the 20th century (Selçuklu Research Center Archive)

Among the factors that played a crucial role in shaping the traditional urban fabric of Sille, the topography of the terrain stands out as a primary influence. The urban structure of Sille is situated on steeply sloped terrain. The presence of this sloped terrain has significantly impacted the settlement's character, necessitating architectural adjustments to accommodate the hilly and steep terrain. In particular, buildings, streets, and the urban fabric have been organized in a terraced manner to adapt to the topography. The passage of the Giret stream, a water source, through the area has facilitated a gradual elevation on the southern slopes of the buildings, streets, and inner neighborhoods. This architectural arrangement not only harmonizes with Sille's topography but also provides visual aesthetics and functionality to the structures. (Tapur, 2009; Akınoğlu & Erdoğan, 2011; Közoğlu, Canan, & Korumaz, 2022). (Figure 9).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Figure 9. Sille city settlement and topography (Sille Municipality Archive)

Another significant factor contributing to the formation of the traditional urban fabric of Sille is the continental climate, characterized by dry and hot summers, as well as rainy and harsh winters, along with the locally sourced building material known as Sille stone, also referred to as 'kan stone.' This material is integral to the region's specific construction techniques, particularly the rubble masonry construction method. Sille stone, a regional material, is extracted from quarries in the vicinity of Sille and is extensively used in the area. It is a preferred material in various types of structures and serves as a crucial component in the regional architecture. Employed in conjunction with traditional construction techniques, Sille stone holds a prominent place in the urban silhouette, imparting a distinctive identity to Sille's architecture and reflecting the experiences of vernacular architecture (Aklanoğlu, 2009; Öksüz & Bollukcu, 2021). (Figure 10).

The Turkish civilian architectural examples in the Sille urban settlement and its surroundings were predominantly constructed during the late 19th and early 20th centuries. These architectural specimens are observed to have evolved through interactions with the region's local culture, traditions, climate conditions, and topographical factors. Furthermore, it is evident that the functionality of the structures in Sille's urban settlement is emphasized, as they are designed on a small scale. These buildings are known to be constructed using traditional, indigenous materials such as Sille stone, wood, adobe, and earth (Aklanoğlu, 2009; Közoğlu, Canan, & Korumaz, 2022). (Figure 10).

Figure 10. View of narrow stone-paved Sille streets and Sille urban settlement (Sille Municipality Archive; Taş, 2013 and Ertaş, 2016)

The traditional Sille houses constitute one of the sub-scales that shape the Sille urban fabric and play a significant role in regional architecture. These houses have achieved their distinctive architectural identity through the skillful use of local materials, particularly Sille stone.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Traditional Sille houses, in addition to Sille stone, reflect the prominent characteristics of the region's architecture through the use of materials such as wood, stone, adobe, and iron, as well as their craftsmanship. Furthermore, Sille traditional houses share similarities with urban-scale Turkish houses that prioritize functionality in their design (Közoğlu, 2019; Közoğlu, Canan, & Korumaz, 2022).

Sille houses, constructed in harmony with the region's topography, are typically designed as two-story buildings with single or double-door entrances. While the traditional Turkish house plan type predominates in the upper floor, it is evident that this design approach varies in the lower floors. The primary living spaces of the house are usually located on the upper floor, whereas the ground floor commonly contains service spaces such as a stable, hayloft, kitchen, and pantry. Stairs are typically made of wood. The first floor, on the other hand, serves as the area where the sofa and rooms are arranged (B. Erkiş, 2016; Sille Street Health Survey Report, 2014). (Figure 11 and Figure 12).

Figure 11. Two-storey Sille houses and general view of Sille houses (Asilkan and Güneş, 2021)

Sille houses generally reflect the traditional Anatolian Turkish house facade typology and features as their facade concept. Windows, doors, wooden decorations, projections, and metal accessories are prominent elements on the facades. The window placements also mirror the traditional Turkish house window arrangement, featuring long and rectangular windows. Due to the influence of the Greeks who were active in the region for a time, some examples exhibit circular forms. The construction system of traditional Sille houses involves wooden lintel stone walls and the use of rubble masonry. Floors, doors, and windows are made of wood, and flat roofs are preferred (Karpuz, 2000; B. Erkiş, 2016; Sille Street Health Survey Report, 2014). (Figure 11).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Figure 12. The most common example of traditional housing plan in Sille urban settlement (Tapur, 2009)

In addition, Sille houses feature functional spaces designed according to local characteristics. Examples of such spaces include the guest room known as 'mabeyin,' the spacious courtyard called 'sofa,' the main living area of the house known as the 'hayat' section, the corridor referred to as 'tahtaboş,' and the small secluded room known as 'izbe.' Inside the rooms, wooden decorative elements such as 'yükçük,' 'ağzıaçıklık,' 'çiçeklik,' and carvings have been used. The absence of a sewage system in Sille houses reflects the construction techniques and infrastructure conditions of the past, indicating that water supply was sourced from wells, nearby springs, and fountains (B. Erkiş, 2016; Sille Street Health Survey Report, 2014). (Figure 12).

c. Hacı Ali Ağa Konağı ve Mimari Özellikleri

In the Sille region of Konya province, at the intersection of Hacı Ali Ağa Street and Nalpınar Street, stands the Hacı Ali Ağa Mansion with inventory numbers 1-3, comprising a basement, ground floor, and first floor, typical of the traditional Sille houses built on sloping terrain. Stylistic analysis dates the structure to the early 20th century. The main entrance of the building is located on the eastern side and is accessed through a double-winged door. It is known that in the past, camels used to pass through this large door, and the house is attributed to Hacı Ali Ağa, after whom the street to the south of the house is named. It is also documented that Hacı Ali Ağa had this house built for himself (Figure 13; Figure 14 and Figure 15).

Figure 13. The location of Hacı Ali Ağa Mansion within the building block (Konya Municipality Conservation-Oriented Zoning Plan Building Conditions Brochure) **Figure 14.**

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Different views of the eastern and southern facades of Hacı Ali Ağa Mansion at various time intervals (Sille Street Rehabilitation Survey Report, 2014)

The structure is privately owned today and is recognized as an authentic example of the architectural style in Sille. Moreover, being a registered building, it is preserved as a cultural heritage. This residence is considered one of the significant structures in the Sille region. Presently, it also reflects the characteristics of a Turkish house in terms of art and architectural history.

The primary material used in the construction of this building is Sille stone, and its roofing consists of a flat earthen roof. The structure is constructed with three floors, including the basement, and is equipped with a balcony extending along the upper floor. This balcony is supported by wooden handrails with wooden support columns. Access to the upper floor from the stone-paved courtyard is provided by a wooden staircase. The upper floor features a plan with an inner living area, and the rooms open up to this narrow, elongated living space. At the end of the staircase providing access to the upper floor, there is a kitchen section. The interior and decorative features of the rooms, while maintaining a simple appearance, include wooden shelves and cabinets, emphasizing woodworking and ornamentation. Wooden cladding is used for the floors of the rooms, and the ceilings are adorned with wooden round beams (See Figure 14 and Figure 15).

Figure 15. The ground floor features a double-winged wooden sentence door of the building, wooden handrails supporting the protrusion on the south facade, and the upper floor's inner living area with rooms (Sille Street Rehabilitation Survey Report, 2014).

Land Use and Orientation

It is observed that the residential units numbered 1-3, located at the intersection of Hacı Ali Ağa Street and Nalpinar Street, which are significant streets in the town of Sille, were designed in accordance with the climate and terrain conditions, aiming to enhance their relationship with the surrounding environment, much like traditional Sille houses. Constructed with vernacular architectural knowledge, the dwelling, like traditional Sille houses, is built in close proximity and in a compact form to prevent heat loss. In this way, an attempt has been made to create a microclimate at the desired level. It is evident that, similar to other traditional Sille houses, the residential unit numbered 1-3 is situated on sloping terrain in a manner that does not obstruct the air, light, and view of another dwelling. This emphasizes the importance of the residence in providing natural ventilation (Figure 16).

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Figure 16. The contiguous layout and orientation of Hacı Ali Ağa Mansion towards the south and east facades (Sille Street Rehabilitation Survey Report, 2014).

The locations of the structures play a significant role in shaping the settlement pattern in the town of Sille, depending on the topography of the land. In this context, residential units numbered 1-3 were constructed in a manner that harmonizes with the terrain by leveraging the land form, much like traditional Sille houses. It is designed in a gradual manner to accommodate the slope of the land, incorporating a basement level that conforms to the incline. Residential unit numbered 1-3 is oriented towards the south and east directions. The entrances to the structure are provided from the eastern facade. It can be observed that in the facades facing south, additional window openings have been created to harness sunlight, striving to passively utilize solar energy (Figure 16).

Spatial Organization and Interior Features

This structure is a three-story residence comprising a basement, ground floor, and first floor. The ground floor of the building follows an inner living area plan, and its square-shaped inner living area is used as a transition point providing access to different rooms and additional functions. The floor of the inner living area is covered with Sille stone, and its ceiling is supported by wooden round beams, a feature commonly seen in traditional Sille houses. The rooms arranged around the inner living area on the ground floor serve various functions. The walls of the rooms are adorned with wooden cabinets and openings, characteristic of traditional Sille houses. The floors of the rooms are wooden clad, and their ceilings are also decorated with wooden round beams (Figure 17 and Figure 18).

The first floor of the structure has a different floor plan compared to the ground floor, and access to the upper floor is provided through the stairwell located on the south facade of the building. Entry to the first floor is gained through a door opening into the inner living area, which extends in a north-south direction. The rooms are positioned in the east and west directions. Similar to the ground floor, the walls of the rooms on the first floor feature wooden cabinets and openings specific to traditional Sille houses. The floors of these spaces are covered with wooden cladding, and their ceilings are adorned with wooden round beams. Colored glass panels integrated into the round-arched windows are used to add movement to the interior of the space. Additionally, in the past, there used to be a protrusion on the southern side of the inner living area, which is now utilized as a balcony (Figure 17 and Figure 18).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

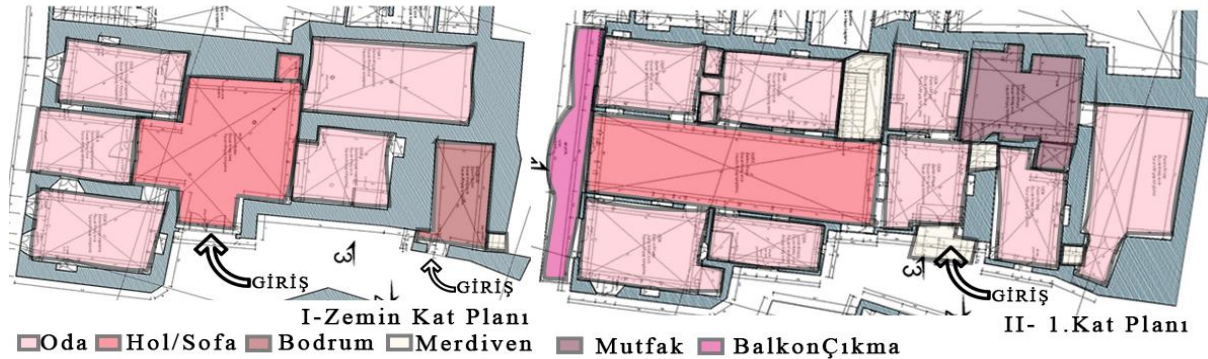

Figure 17. Spatial organization based on the ground floor and first-floor plans of Hacı Ali Ağa Mansion (Figure 17 and Figure 18)

The northern section of the inner living area, extending in a north-south direction, is separated by a three-arched section from the entrance onwards. This design approach is reminiscent of the vestibule areas in Turkish houses and aims to make the space more functional. The floor of the inner living area is covered with Sille stone, and these stones are arranged in an orderly manner, with an octagonal motif in the central section. This motif is typically seen as an ornamentation style in wooden ceilings, but in this house, it manifests itself as an original application made of Sille stone on the floor. The fact that this traditional Sille residence, known as Hacı Ali Ağa Mansion, is adorned with such detailed decorations is believed to be attributed to Hacı Ali Ağa's personal supervision of the construction, indicating that he had it built for himself. In terms of craftsmanship quality, it surpasses other traditional Sille houses and features more elaborate decorations. With these characteristics, Sille Hacı Ali Ağa Mansion constitutes a significant contribution to the region's traditional architectural heritage (Figure 17 and Figure 18).

Figure 18. The interior features and decorative elements of Hacı Ali Ağa Mansion, reflected in the woodworking and cabinets (Sille Street Rehabilitation Survey Report, 2014).

Material Usage and Construction Technique

The fundamental building material utilized in the construction of the structure is rubble stone. Wood and stone materials are prominently featured in the interior spaces. In the design of the outer facade, Sille stone is combined with adobe plaster, and in certain areas, wooden supports are added to ensure the load-bearing capacity of the walls. It has been observed that in recent times, cement plaster has been preferred in some areas. Additionally, in the interior ceiling finishes, apart from wooden round beams, it is evident that covering boards, similar to those on the floor, are employed.

The Use of Materials in Hacı Ali Ağa Mansion

Stone Wood Brick Adobe Earth Metal Concrete

Stone Material

The main construction material of the building is natural stone, and the facades exhibit a partially plastered appearance. Particularly in the basement, attention is drawn to the carefully processed rubble stones obtained from the surrounding quarries. While Sille stone is the preferred main building material, the basement of the structure is constructed with rubble stone. These walls are supported by small rubble stones placed between wooden elements arranged in a triangular pattern on the first floor, and the wall surface is covered with adobe plaster.

Furthermore, the upper part of the ceiling, supported by round wooden beams on the first floor, is covered with Sille stone paving, creating a unique floor. This distinctive stone paving is partially used in the basement and ground floors as well, but it is most prominently featured in the main floor's inner living area (Table 2).

Wood Material

In terms of wood usage in the construction, tree species such as poplar, juniper, and willow were generally preferred. Additionally, pine and pitch pine were used to a limited extent. The ceilings of the structure present a design created with wooden round beams. Furthermore, it has been observed that wood material is used in elements such as doors, windows, especially window sills in the rooms, mirrors, flowerpots, wooden floor coverings, and the lintels of load-bearing walls (Table 2).

Brick Material

In the recent renovation works of the house located at 1-3 Nalpinar Street, it is observed that brick material has been used in the sub-counter walls. (Table 2)

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Adobe Material

Adobe, the traditional building material of Konya, is specially kneaded, molded, and then obtained by drying. The preferred adobe material in Sille houses is observed to be used not only in Konya but also extensively in many regions of Anatolia, especially in the Inner and Southeastern Anatolian regions, due to its effective insulation against hot and cold weather conditions, maintaining moisture balance in indoor spaces, fire resistance, widespread availability, low cost, and environmental friendliness (Bektaş, 1996). In these structures, adobe material is used as plaster in indoor spaces, and it is also observed to be partially used as plaster material on the external facade (Table 2).

Earthen Material

In traditional residential architecture, especially in the Central Anatolia Region, earth is used as the primary roofing material, and the traditional roof design is generally implemented as a flat earthen roof. Over the beams, materials such as reeds (kandıra, saz) or branches (ağaç dalı), grass, specially kneaded torak, and others are spread. Additionally, earth is used in some mixtures as a plastering material on the wall surfaces. Earthen material is also used in the interior spaces of the structure as room plasters and in exterior claddings. (Table 2)

Metal Material

Metal material is observed in window and door frames, as well as in railings. Metal material has been used in the railings of the windows on the ground and first floors, as well as in the recently renovated main entrance door and balcony railings of the structure. (Table 2)

Reinforced Concrete

Material During a recent restoration process, this material was incorporated, particularly in the section later added to the north of the structure, where reinforced concrete material was used as plaster on the floor and walls. (Table 2)

Structural Elements and Facade Typology

The structural elements of Hacı Ali Ağa Mansion include wooden doors and windows, wooden and reinforced concrete stairs regulating inter-floor transitions and level differences, wooden flooring, and round wooden beams. In the traditional Sille residence known as Hacı Ali Ağa Mansion, the windows are made of wood and rectangular-shaped windows and round-arched windows are prominent on the facade, either individually or in groups of three. Additionally, for energy efficiency and to make better use of sunlight, it is observed that windows are mostly placed on the southern facade. (Figure 20 and Figure 21)

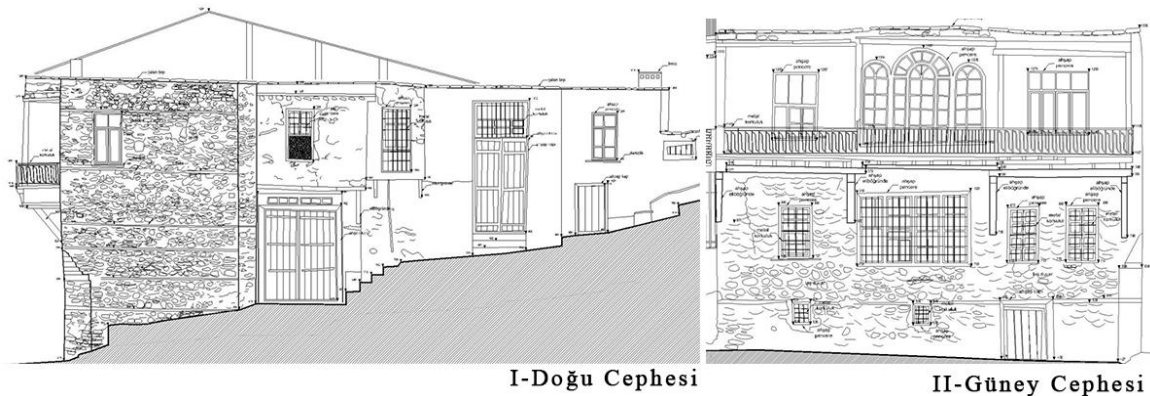

Figure 19. Eastern and western facade views of Hacı Ali Mansion (Sille Street Rehabilitation Survey Report, 2014)

In the past, the protrusion located on the southern facade has now gained the function of a balcony, and this balcony is supported by wooden brackets. The round-arched windows on the first floor feature colored glass, serving as an eye-catching decorative element. The doors in the outdoor and indoor spaces of the structure are made of wood, and it is observed that there are variations in their dimensions according to their respective areas. In this context, it is noted that the entrance doors are larger and more intricately crafted. (Figure 20 and Figure 21)

Figure 20. The Protrusion With Round-Arched Windows on the South Facade and the Eastern Facade of Hacı Ali Mansion (Sille Street Rehabilitation Survey Report, 2014)

6. CONCLUSION and RECOMMENDATIONS

As a result of the conducted research, it has been determined that the historical settlement of Sille, affiliated with the city of Konya, is remarkably rich and diverse within the scope of tangible and intangible heritage. The significance of this rural architectural heritage, formed by examining the traditional residential fabric, which constitutes the historical settlement and area of Sille, stands out prominently. In this study, the Hacı Ali Ağa Mansion, which exhibits the characteristics of a registered residence within the context of traditional Sille residential architecture, was evaluated by analyzing its plan and materials, reflecting its similarities with the Turkish House.

In conclusion, the historical settlement area of Sille and its traditional architecture, distinguished by its historical depth and cultural richness, not only sheds light on the past but also illuminates the present and the future. In this context, Sille city should preserve its status as an important tourist and cultural center, thanks to the rich atmosphere and historical fabric created by its traditional residential fabric.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Therefore, the rich historical heritage of Sille should be passed down to future generations and should be considered as a resource for future researchers. It should not be forgotten that traditional residences are immovable cultural assets, and in the context of preservation and utilization of the vernacular architectural heritage they create, they should be preserved and handed down to subsequent generations.

ABSTRACT

Frequent earthquakes in recent years have brought many problems, especially shelter. Since it takes a long time to meet the need for permanent shelter after an earthquake, the temporary shelter of disaster victims should be met in a short time. In order to meet this need, containers, which are faster to produce, transport and install, are more preferred because their spatial comfort is higher than other sheltering alternatives. Containers with mobile and modular structure also allow different space organisations in terms of design flexibility. However, when the temporary sheltering functions of the containers used after disasters disappear, these building elements are sent to storage areas in an idle manner. In order to prevent the idle storage of these structures with high design flexibility, suggestions have been made within the scope of the study for the re-functionalisation of the containers used after the disaster, especially in the public space after the emergency. These suggestions have emerged as a result of the examination of the examples obtained in the literature research conducted within the scope of the study. This study is intended to guide the practices for the re-functionalisation of the containers that are out of use after the emergency shelter need disappears after the disaster.

Keywords: Disaster, Container, Public Spaces, Recycling.

1. INTRODUCTION

Since the existence of mankind, disasters, which are events that negatively affect societies or the environment and can lead to loss of life and material damages, have been occurring, although their dimensions vary. Disasters are events that disrupt the normal life order of societies and cause damage and destruction.

It is possible to see that natural disasters occurring in the country cause serious damage to the normal functioning and daily life of a society in line with the researches conducted. It affects daily lives and such disasters not only cause human loss, but also can lead to financial, economic and environmental damages. Looking at the current situation, it is seen that the ability of society to overcome these difficulties with its own resources is no longer possible (Canatan, H. (2020).

In Turkey, although there are necessary regulations to reduce earthquake damages, it is clearly seen that the negative effects of earthquakes cannot be prevented. Factors such as rapid population growth, internal and external migration, irregular urbanisation and industrialisation, illegal construction, slum construction, lack of education and inadequate supervision have increased the risk of natural disasters. This situation is clearly seen with the recent disasters that

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

have occurred and finally, a great financial burden is imposed on the country. (UZUNÇIBUK, 2005).

Turkey is a country frequently exposed to natural disasters such as earthquakes, landslides and floods. (Seymen & Akın, 2014). Especially the Marmara Earthquake in 1999 caused great devastation for Turkey. In this earthquake, it is recorded that approximately 18 million people lost their lives, nearly 44 thousand people were injured and more than 20 million people were affected. In the 2011 earthquake in Van, 644 people lost their lives and more than 2,000 people were damaged by the earthquake. Our country also faces flood and landslide disasters every year and these disasters cause great loss of life and property (AFAD, 2014:20; İnal, Kaya & Altıntaş, 2018). Finally, it is stated in both local and international sources that the two separate earthquakes with a magnitude of 7.7 and 7.6, which occurred on 6 February, centred in Kahramanmaraş and were effective in 10 provinces, is one of the rare natural disasters. This disaster has turned into a great tragedy with more than 50 thousand casualties and more than 100 thousand injured according to official figures.

In Turkey, while recognising that natural disasters, especially earthquakes, are inevitable and it is becoming difficult to predict the magnitude, where and when an earthquake will occur, "Disaster and Risk Management" based on science and technology is gaining more and more importance in modern earthquake management. The perspective towards disaster management is changing worldwide and the concept and techniques of "Risk Management" are emphasised more than the traditional approach. In this context, disaster periods and normal periods are handled differently and techniques and managerial approaches specific to these periods are defined as "Disaster Management" and "Risk Management". In this perspective, the activities before, during and after the disaster are considered as different fields of expertise such as "Preparedness" - "Emergency Response (Rescue and First Aid)" and "Normalisation and Recovery of Society" - "Mitigation" activities (Uzunçibuk, 2005).

In disaster areas, people lose their homes and workplaces due to the shaking experienced. The needs of the people of the region who have lost their living spaces begin to arise in many areas. Containers can start to meet the needs of the people of the region in a short time because they are structurally very easy to transport and modular materials that can be shaped modularly. Containers, which can be both a health cabin and a dining hall, can easily return people's living spaces to normal life.

After a while, when the people living in the disaster areas return to their own homes and workplaces, the usage period of the disaster containers is over for that region. Containers have materials that are suitable for reuse in other areas and can also contribute to sustainable energy. They are rectangular and their surfaces are made of sheet metal.

The transport of containers is carried out by cranes and forklifts. With this technical feature structure, it can host a safe living space in every area.

Due to their durable structures and standard dimensions, they can be easily added side by side or on top of each other. It is preferred in modular structures due to its durability. Due to the ability of containers to be relocated, they can be used both as a structure in emergencies and as a structure in different designs.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

In this study, it is aimed to examine disaster containers within the scope of disaster management. It is aimed to pioneer innovative ideas by conducting researches in order to use them in the first aid moment and to make them sustainable in the future.

2. MATERIALS and METHODS

This study aims to be a different branch of a comprehensive research. At the same time, within the scope of this study, many suggestions are developed in order to prevent the containers from remaining idle after the first aid during the disaster. With this study, it is seen that the literature review is made and the existing applications related to this subject are seen within the scope of the study.

As a result of the literature review, it is seen that the containers used after many disasters are left idle in a certain part of the city after the recovery of the city and the transition to a settled order. In response to this situation, an improvement policy has been proposed. The design of new technological, energy-saving, different and social spaces will be examined and put into service in public spaces rather than the containers used in emergencies. In this way, it is planned to create social spaces that are both easy to recycle and sustainable. In the light of past studies, it is aimed to guide applications that are sustainable, open to new technologies and pay attention to energy saving.

3. FINDINGS and DISCUSSION

Turkey is constantly faced with earthquake risk due to its geographical location. More than half of the disasters in the last sixty years have been earthquakes. Many earthquake victim families have been confined to temporary housing solutions for long periods of time. Transition to permanent housing often requires a process that lasts for years. Factors such as the psychological effects experienced after the earthquake and the length of the transition to permanent housing, housing conditions and the design of temporary shelters are more important (Ünal & Akin, 2017).

While everything is progressing rapidly, the greatest need in disaster areas has emerged to create fast and reliable spaces. It has been determined that both green buildings and containers, which can be converted in a short time and easily transportable, are very accurate materials in terms of use (Yonar, 2009).

Containers are elements of high importance here. Accordingly, after the needs are met in the disaster areas, the design of the containers, which have expired, without leaving them idle in a corner, will provide savings in terms of economy and time and will serve people in public spaces.

From both an economic and durability point of view, a conventional building is under construction in order to create kindergartens, leisure areas, health cabins, kiosks in cities.

There is a significant difference between the cost of materials such as timber, bricks, mortar, etc. and the cost of a new container, and this difference is maintained in terms of durability. Not only the supply of materials, but also much more manpower and energy is needed in a traditional building. Since it requires manpower, cost of materials and licence during construction, it is inevitable to experience delays in delivery and completion time. On the other hand, work can be done to create a small house or office with one or two manpower in containers. In addition, licence etc. does not create a waste of time for permits. Another

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

prominent feature is that containers can be combined with each other and brought together and arranged in different shapes and sizes. It is possible to design and put into use in accordance with each area (Madkour, 2017).

For example, it is seen that a container serving as a health cabin in the disaster area reduces the indoor temperature up to eight per cent when we equip the roof with plants by making use of nature. When we choose the material that can absorb heat in the windows, it is possible to heat the interior space by making use of the outside temperature very easily. Using solar energy in lighting, heating and cooling systems with solar panels to be installed on the roof or outdoor unit will contribute to sustainable energy saving. When this container, which is insulated and whose windows are designed according to the climate, ends its service in the disaster area, it can be moved to another region without requiring any additional change and can be used not as a health cabin but as a venue hosting performing arts.

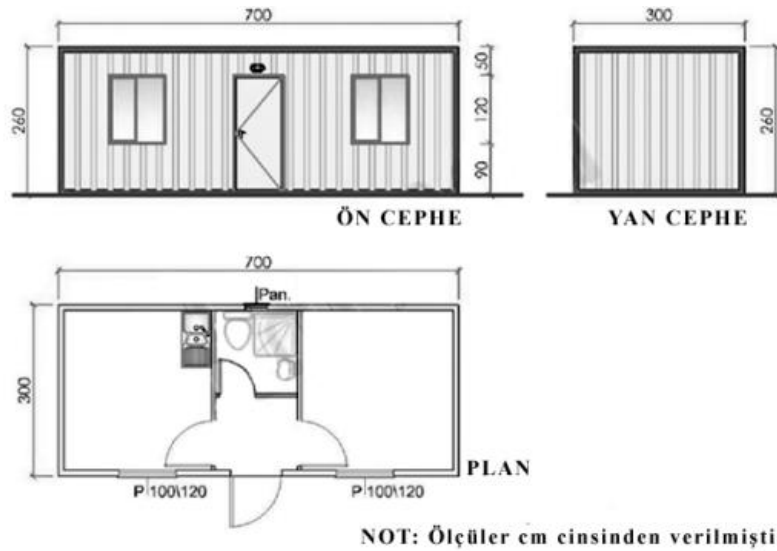

Figure 1. Temporary disaster housing plan and facades (Ünal & Akın, 2017)

The containers used to meet the need for temporary shelter consist of 21 m² seating area and contain 2 rooms, kitchen, bathroom and toilet (Picture 1) (Ünal & Akın, 2017).

It is seen that there is a 120 cm long kitchen counter/cabinet with a recessed steel sink in one room in order to meet the kitchen needs in disaster houses. Apart from the counter, there is no furnishing for the kitchen space (Picture 2, 3) (Ünal & Akın, 2017). It is seen that there is a 120 cm long kitchen counter/cabinet with a recessed steel sink in one room in order to meet the

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

kitchen needs in disaster houses. Apart from the counter, there is no furnishing for the kitchen space (Picture 2, 3) (Ünal& Akın, 2017).

Figure 2. Kitchen (Ünal& Akın, 2017) **Figure 3:** Kitchen (Ünal & Akın, 2017)

This bathroom is 1.5 metres wide and 1.5 metres long, with a total area of 2.25 square metres. The bathroom is equipped with a washbasin, shower cubicle, electric water heater (thermosiphon), an alufranga toilet and a ventilation window. However, there is no storage space in the bathroom. This space has the ability to receive natural light and a luminaire on the ceiling is used for night lighting (Ünal& Akın, 2017).

According to the available information, the two rooms, which are 2.8 metres wide and 2.6 metres long, cover a total area of 7.28 square metres. These rooms do not contain any furniture or items for sitting or resting. Victims of earthquakes or other disasters use the belongings they survived or were able to obtain. The walls and ceiling of both rooms are painted in white colour. Each room receives natural sunlight through windows on one side of the room, while overhead lighting is used at night. There is no storage space in this container dwelling (Ünal& Akın, 2017).

As a result of these, the project examined the design of new technological, energy-saving, different and social spaces and opening them to service in public spaces instead of leaving the containers idle after their use for emergency shelter and needs in both green building and disaster areas (Beyatlı, 2010).

The example in Figure 4 below is one of the best examples of how disaster containers can be combined, divided and resized. We can talk about their transformation into youth centres to be designed in similar ways and used in public spaces. Since it is deformed while being used only as a disaster shelter, after a few repairs, modifications and designs, it can be adapted to every area and put into service quickly.

Figure 6. Transformation of disaster containers into free service areas

In the picture below, it was used as a health cabin in the disaster area, and then it was transformed into free toilets, masjids, baby care rooms that can be used by many people in public spaces by installing installations inside.

4. CONCLUSION and RECOMMENDATIONS

The use of containers as an alternative to the need for emergency shelter after a disaster and the possibility of recycling the material makes them a rational choice for contemporary designers and users. It would be more economical than building a new traditional building to transform the containers, which can actually be reused after a little organisation and repair, into quality living spaces instead of waiting for them to rot in a corner in an idle state.

In disaster areas, containers are left aside for reasons such as expiry or wear and tear. Recycling of containers is important in terms of sustainable architecture. These transformations stand out as a rational choice for contemporary designers and users. Structural deficiencies, insulation, acoustics, natural lighting issues of containers can be eliminated with very simple architectural solutions. It would be more economical than building a new traditional building to transform the containers, which can actually be reused after a little organisation and repair, into quality living spaces instead of waiting for them to rot in a corner in an idle state.

The designed new spaces can be combined with each other like giant logo pieces and transformed into large social areas. It is known that such projects with traditional structures will be high in time, energy and economic terms. However, it can be transformed into social spaces in public spaces that can be easily transported from disaster areas to city centres where needs are met. Thus, it is expected that it will attract people's attention more and inspire sustainable energy.

ABSTRACT

With the increase in excessive rainfall due to climate change, cities and their citizens are exposed to floods. In this exposure, many factors play an important role in determining the vulnerability of city population. At this point, social, economic and demographic characteristics of the population are effective in determining the level of vulnerability to disasters. Socially vulnerable groups have inadequacies in terms of compensating the damages when exposed to disasters. On the other hand, the development patterns of cities are also very effective in terms of exposure to floods due to excessive rainfall. Although it is stated in the literature that socially disadvantaged groups live in disaster-prone areas, it can be argued as a hypothesis that such a generalization can't always be made due to the advantages offered by various regions within the city such as scenery and proximity to the center. In order to test this hypothesis, the study aims to determine the vulnerability levels of the spatial location choices of socially vulnerable groups. For this purpose, social and spatial vulnerability levels were determined at the neighborhood scale in Izmir, which was selected as the study area, and the levels obtained were examined comparatively. As a result, it was found that 35% of the socially vulnerable population is located in spatially disadvantaged areas. Therefore, it is seen that socially vulnerable groups don't always choose to live in spatially disadvantaged areas.

Keywords: Climate Change, Excessive Rainfall, Social Vulnerability, Spatial Vulnerability.

1. INTRODUCTION

Climate change is one of the most important problems of our time, affecting all systems of nature and posing a serious threat to human life. Climate change has many impacts that increase in intensity over time and damage ecological and social systems. Excessive rainfall is one of the most important impacts of climate change. According to IPCC (2021), since the 1950s, there has been an increase in the frequency, intensity and severity of extreme rainfall in terrestrial areas due to climate change. The increase in the intensity and duration of precipitation leads to flooding disaster events in cities. Flood disasters caused by excessive and sudden rainfall adversely affect cities and the population living in cities. Flooding in cities causes many vital, physical, social and economic problems such as property damage, destruction of livelihoods, destruction of urban infrastructure systems, disruption of transportation, mixing of clean water and sewage water, spread of water-borne infectious diseases, injury and death.

September 14-15, 2023, Naples, Italy

Cities, where population, structural assets and economic activities are concentrated, are highly vulnerable to the impacts of climate change. Today, cities and their inhabitants are frequently exposed to disaster events caused by excessive rainfall. Many factors play an important role in determining the vulnerability of urban population when exposed to disasters caused by excessive rainfall. At this point, social, economic and demographic characteristics of the population are very effective in determining the level of being negatively affected by flood disasters. In terms of social characteristics; children, the elderly, women, the disabled and the poor are the disadvantaged groups that are most affected by disaster events that develop with excessive rainfall (Cutter, Emrich, Webb, & Morath, 2009; Baker, 2012). Socially vulnerable groups are most likely to be harmed and affected by disasters associated with excessive rainfall (Rufat, Tate, Burton, & Maroof, 2015). When exposed to disasters, these groups have inadequacies in terms of compensating for the damages incurred and consequently have a low capacity to recover from damages. In this context, it is frequently stated that the urban poor are the most vulnerable groups (Gökçe, 2017).

On the other hand, the spatial development patterns of the city in the context of location selection are also very effective in terms of exposure to disasters that may occur in case of excessive rainfall. Location characteristics such as the height of the city from the sea, its topographic structure, coastal length, and settlement status in stream floodplains play an important role in determining the level of spatial vulnerability to excessive rainfall. People living in stream floodplains, seashores and low-slope areas face flood disasters more frequently.

In general, it is stated in the literature that socially disadvantaged groups live in disaster-prone areas such as river floodplains and coastal areas (Dodman & Satterthwaite, 2008; Dangol & Carrasco, 2019). However, it can be hypothesized that the opportunities offered by various regions within the city, such as views and proximity to the center, cause socially advantaged groups to choose locations in disaster-prone areas, and therefore such a generalization can't always be made. In order to test such a hypothesis, this study evaluates the location choices of vulnerable groups based on their social characteristics in vulnerable regions in terms of their spatial characteristics. In order to make this assessment, indicator-based vulnerability analysis was conducted at the neighborhood scale in Izmir, which was selected as a sample area, and social and spatial vulnerability levels were determined and the obtained levels were examined comparatively.

2. MATERIALS and METHODS

Case Area

The 11 central districts of Izmir province constitute the study area (Figure 1a). In the neighborhood scale study, a total of 388 neighborhoods, including Balçova (8 neighborhoods), Bayraklı (24 neighborhoods), Bornova (45 neighborhoods), Buca (47 neighborhoods), Çiğli (27 neighborhoods), Gaziemir (16 neighborhoods), Güzelbahçe (12 neighborhoods), Karabağlar (58 neighborhoods), Karşıyaka (27 neighborhoods), Konak (113 neighborhoods) and Narlıdere (11 neighborhoods) were included (Figure 1b).

Explanation of the Indicators

Social and spatial indicators were utilized to determine the levels of social and spatial vulnerability to excessive rainfall (Table 1). Each social and spatial indicator identified to identify vulnerabilities is explained below, along with the reasons for their selection in accordance with the purpose of the study.

Table 3. Indicators used in vulnerability analysis

Name Of Indicator	Indicator Factor	Abbr.	Unit	Definition	Data Sources	Type Of Indicator
Female Population	Social	SO _F	person	Number of women and girls	TUIK	Sensitivity
Child Population	Social	SO _C	person	Number of children (0-14)	TUIK	Sensitivity
Elderly Population	Social	SO _E	person	Number of people aged 65 and older	TUIK	Sensitivity
Disabled Population	Social	SO _D	person	Number of people with disabilities	TUIK	Sensitivity
Education Status	Social	SO _{ES}	%	Literacy rate of neighborhoods (15 years and older)	TUIK	Adaptive Capacity
Access to Health	Social	SO _{AH}	m	Proximity to the nearest hospital from the very center of the neighborhood	Measured by the authors using Google Earth Pro	Resilience
Socioeconomic Development Level	Social	SO _{SD}	person	Socio-economic development ranking of districts	Republic of Turkey Ministry of Industry and Technology	Adaptive Capacity
Slope	Spatial	SP _S	%	Average slope of the neighborhood	Measured by the authors from SRTM digital elevation map	Resilience

Rate of Construction in Stream Floodplain	Spatial	SP _{RC}	%	Rate of construction in the stream floodplain to the size of the neighborhood	Measured by the authors using Open Street Map (OSM)	Exposure

Social Indicators

Floods caused by excessive rainfall make urban population vulnerable, causing many injuries, deaths and damage to property and assets. At this point, social, economic and demographic characteristics of the urban population are very important in determining the vulnerability of population exposed to disasters. Age, gender in terms of demographics; income, poverty, education level and health in terms of socioeconomics are among the main factors affecting social vulnerability (Rufat, Tate, Burton, & Maroof, 2015; Kirby, et al., 2019). In this context, women, children, the elderly, the disabled, and the poor stand out as vulnerable groups most affected by disaster events (Cutter, Emrich, Webb, & Morath, 2009; Baker, 2012; Rufat, Tate, Burton, & Maroof, 2015). These vulnerable groups create evacuation difficulties during disasters due to their household dependency and limited mobility. Therefore, socially vulnerable groups have a high likelihood of being harmed and affected by disaster risks due to excessive rainfall and a very low capacity to cope with the economic damage costs caused by disasters.

The level of socioeconomic development is also important in terms of the potential to cope and adapt to disaster risks. In societies with more economic assets and material resources, the capacity to cope with floods is higher and vulnerabilities are lower (Herslund, et al., 2016). In other words, the capacity of poor households to cope with damage costs from flood disasters is much lower compared to rich households (Rufat, Tate, Burton, & Maroof, 2015). Factors such as education level, literacy rate and health also affect social vulnerability (Rasch, 2016; Rufat, Tate, Burton, & Maroof, 2015). The high level of education of societies increases the level of consciousness and awareness against disaster risk. Societies with previous disaster experience are considered to be less vulnerable as they are more cautious against disasters (Herslund, et al., 2016). Access to health is very important in terms of the capacity to cope with health problems that may occur during and after a disaster. For these reasons, child, elderly, women and disabled population, socioeconomic development level, education level and health access were used as social indicators in the study (Table 1).

Spatial Indicators

Environmental risks and climate-related disasters have inequalities in their geographical spatial distribution (Chuang, Chen, & Lin, 2020). For this reason, the extent to which different urban regions are negatively affected by climate change-related disasters varies according to the geographical characteristics of the area where they are located (Aydın & Kahraman, 2022). Therefore, in case of exposure to disasters caused by excessive rainfall, spatial development patterns in the context of the city's location characteristics are important. For this reason, factors such as the city's elevation above sea level, slope and settlement status in stream floodplains are considered as indicators of spatial vulnerability. As the altitude of a city decreases, its

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

susceptibility to flood disasters increases. Low slope is also identified as an indicator that increases spatial vulnerability. Floods are more common in flat areas with low slopes. Another spatial indicator is the rate of construction in stream floodplains. As a result of the opening of naturally flowing stream beds to construction, the inability to drain excessive amounts of rainwater during precipitation leads to flood disasters in cities. Thus, the rate of construction in stream floodplains is considered as an indicator that increases vulnerability.

METHOD

In the literature, there are various vulnerability calculation formulas that are defined as a function of vulnerability, taking into account components such as impact, exposure, sensitivity, resilience and adaptive capacity. The basic approach in vulnerability calculations is that impact severity, exposure and sensitivity have a positive effect on vulnerability, while resilience and adaptive capacity have a negative effect on vulnerability (see Luers, 2005; Gbetibouo & Ringler, 2009; Balica, Wright, & Meulen, 2012; Aydın & Kahraman, 2016). Therefore, as impact, exposure and sensitivity increase, vulnerability increases; as resilience and adaptive capacity increase, vulnerability decreases. Accordingly, in this study: $Vulnerability = (Exposure \times Sensitivity) / (Resilience \times Adaptive \ Capacity)$, social and spatial vulnerability levels were calculated.

$$\text{Social Vulnerability Formula} = \frac{SO_F \times SO_C \times SO_E \times SO_D}{SO_{ES} \times SO_{AH} \times SO_{SD}}$$

$$\text{Spatial Vulnerability Formula} = \frac{SP_{RC}}{SP_S \times SP_E}$$

Before applying the social and spatial vulnerability formulas, the values were normalized so that indicators obtained from different types could be examined together. After normalizing the indicator data, social and spatial vulnerability calculations were made. The results of the calculations were spatialized using the ArcGIS program. The results were categorized in 5 levels as very high (level 1), high (level 2), medium (level 3), low (level 4), very low (level 5) using the Geometric Range Classification Method in Geographic Information Systems (GIS). Thus, maps of social and spatial vulnerability levels were produced.

3. FINDINGS

As a result of the calculations based on the indicators, maps of social and spatial vulnerability levels were created. These vulnerability maps contribute to the examination of the relationship between social and spatial vulnerability levels. When the vulnerability levels in terms of social characteristics against excessive rainfall are examined, it is seen that 12% of the neighborhoods are in the very high (level 1), 21% in the high (level 2), 23% in the medium (level 3), 19% in the low (level 4) and 25% in the very low (level 5) vulnerability category. Accordingly, 33% of the neighborhoods have very high and high vulnerability levels, while 67% have very low, low and moderate vulnerability levels.

The most socially vulnerable areas were determined to be parts of coastal areas (Bayraklı, Karşıyaka, southwest of Konak) and city centers (Buca, Bornova, Gaziemir, Karabağlar). The results show that, in general, vulnerability decreases from the urban built-up area to the periphery. Therefore, the peripheries of the city have the lowest social vulnerability as the least populated areas (Figure 2).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

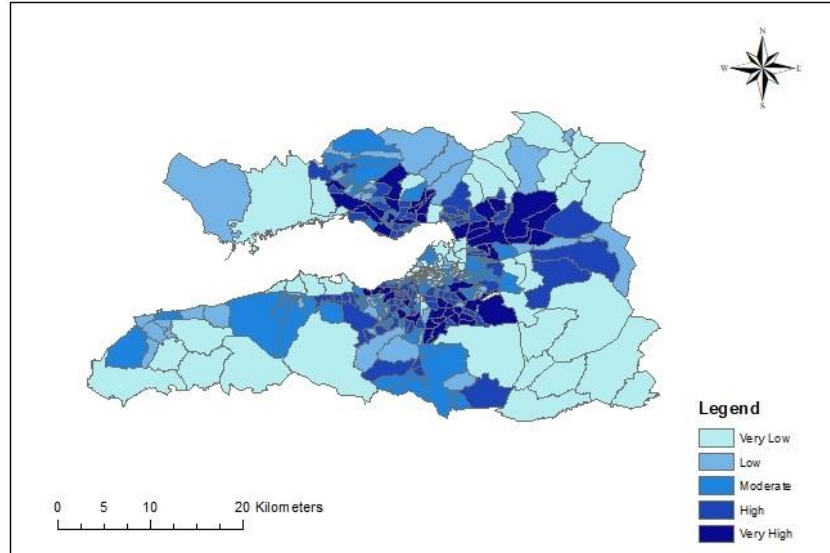

Figure 6. Social vulnerability levels of neighborhoods to excessive rainfall

When the spatial vulnerability levels based on location characteristics against excessive rainfall are examined, it is seen that 15% of the neighborhoods have very high (level 1), 15% have high (level 2), 4% have moderate (level 3), 7% have low (level 4) and 59% have very low (level 5) vulnerability levels. Therefore, 30% of the study area has very high and high spatial vulnerability levels, while 70% has very low, low and moderate spatial vulnerability levels.

In terms of spatial characteristics, some of the coastal areas (Çiğli, Karşıyaka, Bayraklı, Balçova, Narlidere, Güzelbahçe) and stream flooding areas within the built-up area (Bornova, Buca, Karabağlar, Gaziemir) were identified as areas with very high and high vulnerability (Figure 3).

Figure 7. Spatial vulnerability levels of neighborhoods to excessive rainfall

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

In line with the purpose of the study, a matrix table was created to understand the relationship between social vulnerability to excessive rainfall and spatial vulnerability based on location characteristics and to make a comparative analysis (Table 3). Table 3 below presents the distribution rates of social vulnerability levels in terms of spatial vulnerability levels.

Table 4. Distribution of social vulnerability levels in terms of spatial vulnerability levels

		Levels of Spatial Vulnerability				
		Level 1 (%15)	Level 2 (%15)	Level 3 (%4)	Level 4 (%7)	Level 5 (%59)
Level of Social Vulnerability	Level 1(%12)	%28.3	%19.5	%6.5	%2.2	%43.5
	Level 2(%21)	%12.2	%15.8	%3.6	%7.3	%61
	Level 3 (%23)	%10	%15.5	%3.3	%12.2	%59
	Level 4(%19)	%13.5	%20.3	%4	%4	%58.2
	Level 5(%25)	%16.7	%9.4	%2.1	%8.3	%63.5

When the distribution of vulnerability levels is analyzed, it is interesting to note that 43.5% of the population with the highest social vulnerability (Level 1, 12%) live in the most spatially advantageous regions. On the other hand, 35% of the population exhibiting very high and high social vulnerability (Level 1 and 2), 35% of the population exhibiting very high and high social vulnerability (Level 1 and 2), 5% of the population exhibiting moderate social vulnerability (Level 3), and 60% of the population exhibiting low and very low social vulnerability (Level 4 and 5). Therefore, 35% of the socially vulnerable groups were found to be located in areas with vulnerable spatial characteristics such as coastal areas (Bayraklı, Karşıyaka), areas just behind the coast (Çiğli, Bayraklı, Karşıyaka) and stream flood areas (Buca, Bornova and Karabağlar city centers). It is seen that 60% of the socially vulnerable groups chose to live in areas with very low and low spatial vulnerability such as the coastal edge (southwest of Konak) and urban centers (Gaziemir, Karabağlar, Buca, Bornova).

Among the population with very low and low social vulnerability, 29.5% live in areas with very high and high, 3% in areas with moderate and 67.5% in areas with low and very low spatial vulnerability. Thus, 29.5% of the socially less vulnerable groups were found to be located in coastal areas (Güzelbahçe, Narlıdere, Balçova, Çiğli and northeast of Konak) with very high and high spatial vulnerability. Another 67.5% of the less vulnerable groups based on social characteristics were located in areas with very low and low spatial vulnerability. These areas are mostly located on the peripheries of the city.

4. CONCLUSION

In this study, firstly, social and spatial vulnerability levels to excessive rainfall are determined. A comparative analysis of the identified social and spatial vulnerability levels based on location characteristics is presented. The findings revealed that the social and spatial vulnerability levels of neighborhoods may show regional similarities and/or differences. In other words, there is

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

no consistency between the vulnerability of the population living in the neighborhoods based on their social characteristics and the spatial vulnerability to excessive rainfall due to the physical location of the neighborhood. Therefore, it is observed that socially vulnerable groups are not always located in areas that are vulnerable in terms of their spatial characteristics. Although it is known that the socioeconomic and demographic characteristics of the population are very important in terms of the capacity to cope with disasters, the results of this study conducted in the case of the city of Izmir also form the basis for a discussion that the location characteristics of the living spaces of urban population may be of primary importance in combating disasters caused by climate change. Therefore, it is clear that making disaster resilience spatial location decisions in urban planning processes is important within the framework of adaptation policies.

ABSTRACT

Today, factors such as climate change and urbanization are complicating the management of water resources and leading to increased water scarcity in urban areas. In cities, rainwater is typically collected through drainage systems and subjected to treatment processes. However, the effectiveness of these processes remains limited and systems can overflow during periods of rainfall. At this juncture, rainwater recycling in urban areas carries great importance in terms of water resource conservation and sustainability. The integration of green infrastructure systems and modern technologies provides environmental and economic benefits while optimizing water management. Green infrastructure systems enable the natural management and infiltration of rainwater. For instance, rain gardens and bioswales capture, purify and naturally permeate rainwater into the soil. Designed soils contribute to rainwater recycling, enhancing the natural infiltration process of water. Furthermore, recycled rainwater can be used for irrigation purposes, contributing to the preservation of freshwater resources. With current technology, tools like unmanned aerial vehicles and smart water measurement can be used to monitor and evaluate the performance of rainwater management systems. This paper examines the potential of green infrastructure technologies for capturing, recycling, and reusing rainwater. It proposes how rainwater recycling can be utilized as an innovative and effective method for sustainable water management in urban areas. These approaches contribute to the preservation of water resources and increase resilience against the adverse effects of climate change. They also aid in enhancing the quality of life for communities, protecting the ecosystem, and managing water resources sustainably.

Keywords: Rainwater, Sustainability, Urbanization, Infrastructure, Resilience.

1. INTRODUCTION

The rapid population growth in urban areas worldwide and the effects of climate change have made water scarcity one of the most pressing issues of today. This situation necessitates the creation of sustainable water management strategies for cities. Rainwater recycling is at the forefront of these strategies, with many successful examples implemented in various cities drawing attention.

Today, factors such as climate change and urbanization are complicating the management of water resources, leading to increased water scarcity in urban areas. In urban regions, rainwater

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

is typically collected through drainage systems and subjected to treatment processes. However, the efficiency of these processes can be limited, and during heavy rainfall, systems can become overwhelmed. At this point, rainwater recycling in urban areas becomes of great importance for the conservation of water resources and sustainability. The integration of green infrastructure systems and modern technologies provides environmental and economic benefits while optimizing water management.

Grey and green infrastructure technologies can play a significant role in managing rainwater and preventing potential flooding events. Grey infrastructure captures, treats, and discharges rainwater using concrete and steel pipes, pools, and other structural components (Rueter, 2014).

Green infrastructure systems offer natural means of managing and infiltrating rainwater. For instance, rain gardens and bioswales capture rainwater, treat it, and allow it to naturally infiltrate the soil (Harnik & Martin, 2016).

2. Approaches for Capturing, Recycling, and Reusing Rainwater

With climate change, the frequency and intensity of storms are increasing. Additionally, due to land development, the amount of impervious surfaces and pollutants are also on the rise. This emphasizes the importance of rainwater management. Capturing, recycling, and reusing rainwater have become a crucial necessity for urban water sustainability. These approaches include:

a. Engineered soils – Processed lands

Soils developed with engineering applications are created by combining various organic and inorganic components (sand, clay, mulch, etc.). The mixing of these components in specific ratios, and in some cases using iron-coated sand or nanoparticles-treated soils, can significantly enhance the soil's water absorption and pollutant removal abilities. These characteristics allow the soil to slow down natural rainwater flow and capture pollutants, sediments, and oils present in the rainwater.

Global practices demonstrate the efficacy of processed soils and nanoparticles. For example, at Wooster College's campus in Ohio, Osorb, a silica-based nanoparticle capable of absorbing oil and other pollutants in water, has been utilized (O'Brien & Walton, 2012). This implementation significantly improved water quality, and plants were observed to thrive in this soil mixture.

Effectively holding rainwater in the soil plays a critical role in water management. Processed soils can reduce water evaporation and promote groundwater infiltration. Studies on the water retention capacities of different soil components, like sand, clay, and organic matter, show how engineering applications can optimize these capacities. Particularly in urban areas, soil engineering practices are becoming increasingly vital for effective rainwater management (Fecht, 2013).

b. Underground storage basins

According to the United States Environmental Protection Office, Municipal Technology Branch, (2001), underground storage basins are structures designed to store rainwater below ground. Not only can they reduce flood risks in cities, but they can also enhance water's reusability. Especially during heavy rainfall periods, these basins control rainwater and prevent overexploitation of surface water resources. Underground basins are a prevalent grey infrastructure solution for rainwater management and can be especially beneficial in urban

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

settings. When combined with rainwater capture or irrigation technologies, underground basins can help manage floods while reducing water bills.

For instance, the development of Wescott Park in Northbrook City, Illinois, can be highlighted. Under the Main Stormwater Management Plan, the city has implemented various infrastructure projects to mitigate flooding risks. Among these projects is the enhancement of a storm sewer connected to a 7.5 million-gallon storage chamber located beneath the park's play areas. Additionally, the park management set up an electronic rainwater collection system, allowing the stored water to be used in a new grass irrigation system and pumped into truck-mounted tanks for watering trees and cleaning streets and sewers. Such an implementation reduces water usage, cuts down on irrigation costs, and decreases the risk of flooding in the vicinity (Wescott Park Stormwater Storage Facility, 2016).

c. Drones

Drone technology holds significant potential in optimizing rainwater collection and distribution methods. Monitoring through drones can pinpoint the most appropriate rainwater collection sites, allowing for more effective water management strategies.

Drones can assist in monitoring green and grey infrastructures, sampling the quantity and quality of water, and facilitating efficient rainwater management (Macalla, 2015).

Drones can access challenging areas and can be used to produce consistent datasets (WEF Stormwater Institute, 2015). Moreover, in urban settings, they can be vehicles for capturing public interest and fostering citizen awareness.

d. Real-time control and continuous monitoring and adaptive control

Real-Time Control is a technological approach that enables stormwater management infrastructure to quickly adapt to changing environmental conditions. The efficiency of stormwater recycling can be enhanced through continuous monitoring and real-time control. Adaptive control systems optimize stormwater management based on changing weather conditions and water needs. This technological approach plays a critical role in preserving water resources.

Real-Time Control improves the existing stormwater infrastructure using sensors and software (Kerkez et al., 2016). These systems rely on weather forecasts to effectively utilize capacity, capture water, and remove pollutants. They control the function of the infrastructure based on real-time data. However, technical challenges require oversight by personnel, and weather forecasts may not always be accurate.

In real-world applications, in Lenexa, Kansas, an example can be found where existing stormwater ponds have been enhanced with CMAC technology in collaboration with OPTi Technologies.

This technology has been used to adjust the input and output parameters of the pond based on weather forecasts. For instance, when the expected rainfall amount increased, the pond levels were lowered. Also, when there was a 70% or higher chance of rain, the valves were adjusted to drain the water. This application demonstrates how Real-Time Control and CMAC technologies can optimize stormwater management. However, in practice, additional infrastructure measures had to be taken to prevent debris from clogging the system (Jacobs, 2017).

e. Rainwater harvesting

Rainwater harvesting is a method of collecting, storing, and directing rainfall for various purposes. This technique is often used for applications such as landscaping, livestock, fire prevention, and slow water release to the soil. Rainwater harvesting systems can vary in size and complexity; however, they typically consist of a water catchment surface, a conveyance system, storage, distribution, and treatment components. In most cases, the collection surface is a roof equipped with gutters and pipes that direct the rainwater into a cistern. This technique assists in effectively managing rainwater, reducing surface runoff and flooding, and lowering overall water costs.

Rainwater collected from roofs, gardens, and other surfaces can greatly contribute to water savings. Especially in arid regions, rainwater harvesting plays a crucial role in effectively managing water resources.

Real-world examples provide tangible demonstrations of how this technology can be applied. For instance, the Cloud House project in Springfield, Missouri uses rainwater harvesting to illustrate the connection between the water cycle and food production (Stormwater Report, 2017).

The Rotterdam Basin, created by Rotterdam-based designers DoepelStrijkers, demonstrates how cities can adapt to climate change and increasing rainfall. This structure is made from recycled plastic rainwater pipes and collects and drips rainwater into a pond. Both projects showcase how rainwater harvesting can be designed as interactive public exhibits to raise awareness about water and environmental issues (Cooke, 2016).

f. Greywater recycling

Greywater recycling allows for more efficient use of water resources for toilet flushing, garden irrigation, and other purposes. In many cases, greywater recycling can replace the use of potable surface and groundwater sources for irrigation, enhance the value of the water used, and improve plant growth by providing small amounts of nitrogen and phosphorus. Water conditions should be frequently tested using remote sensors and manual observations to address concerns related to human health and the environment.

g. Permeable paving

Permeable paving can replace traditional concrete and asphalt to allow water to seep into the ground, reducing the load on the stormwater drainage system, cooling the area, and preventing floods. While the material is weaker than concrete and requires more maintenance, it can be used in many areas and can manage stormwater effectively, reducing long-term maintenance costs.

In 2011 in California, permeable pavements were placed in certain sections of the parking lots in Oak Park, located in Santa Barbara. While the permeable pavement is not situated in driving corridors due to heavy traffic, it is present over parking spots. Even with only specific portions of the parking lot being permeable, it significantly increased the overall permeability of the site, reduced water runoff, and increased water infiltration into the site.

This example shows that when applied correctly, permeable paving can offer significant ecological and operational benefits.

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

h. Green roofs

Adding vegetation to building roofs collects rainwater and provides insulation. Green roofs not only enhance the energy efficiency of buildings but also contribute to urban water management. Green roofs assist with low-impact stormwater management and also cool the underlying structure. They conserve water and energy, potentially improving public health and well-being, but require buildings with appropriate load-bearing capacity and space. They also demand more maintenance than traditional roofs.

In 2001, a semi-intensive green roof project was implemented at the Chicago City Hall as part of the Urban Heat Island Initiative in response to a deadly heatwave in the city. The project yielded positive impacts in terms of biodiversity, energy savings, and stormwater management. Compared to surrounding roofs, it retained 75% of the rainwater that fell on it, reduced the building's energy consumption costs by over \$5,000 annually, and decreased noise pollution by up to 40 decibels (Buchanan, 2015).

i. Smart water metering

The integration of sensor technology into water management enables effective monitoring of water usage and rainwater recycling. This aids individuals and communities in becoming more conscious about water conservation. Smart water metering can be considered a vital tool for sustainable use of water resources and enhanced energy efficiency.

Smart water metering services are usually implemented in two ways. Firstly, Automatic Meter Reading (AMR) service, a more cost-effective option, gathers water usage data and provides this information to the service provider, offering a basic service. On the other hand, the Advanced Metering Infrastructure (AMI) service, a higher-cost option, employs in-ground sensors and two-way digital communication. Smart water meters simplify data collection, can be used to detect leaks, and facilitate communication among maintenance personnel. The collected data can be analyzed to inform users and public services about water usage trends and to invest in new technologies. Furthermore, smart meters can be combined with greywater recycling systems to determine how greywater can effectively contribute to irrigation.

3. CONCLUSION

Urban areas are increasingly facing water crises due to various factors, including climate change, population growth, and insufficient infrastructure. In this context, expanding rainwater recycling practices plays a crucial role in sustainable water management. The integration of technology and green infrastructure encourages the conservation and sustainable use of water resources. Adopting such innovative approaches for water management in urban areas will reduce future water scarcity risks. Especially considering the challenges posed by climate change and urbanization, the adoption of these approaches is necessary.

Sustainable water management in urban areas is becoming an increasing necessity. Rainwater recycling is used to address this need through various methods and technologies. Some of these methods utilize traditional grey infrastructure systems, while others employ green infrastructure systems. However, both approaches have their advantages and limitations. For optimal results, the integration and adaptation of both approaches are required according to unique geographical and climatic conditions. Broad-scale applicability of such approaches requires collaboration among relevant municipalities, NGOs, the private sector, and local communities. In regions at

risk of water scarcity, rainwater recycling and sustainable water management could be the key to economic and environmental sustainability.

Thanks and Information Note

I would like to extend my gratitude to everyone who contributed to the 3rd International Symposium on Architectural Sciences and Applications (IArcSAS) and to my esteemed professor, Prof. Dr. Murat Akten.

ABSTRACT

Effective management and user interaction of urban landscape areas have critical importance amidst the rising urban population and changing social needs. This study investigates the integration of digital technologies in urban landscape areas, examining their operation, access, security, and user interactions. Specifically, it focuses on the advantages and disadvantages that Wi-Fi, Geographic Information Systems (GIS), mobile applications, and Internet of Things (IoT) technologies offer in the management and user interactions of urban landscape areas. The spread of mobile technologies and the increased Wi-Fi accessibility encourage user participation and interaction in public spaces, enhancing the appeal of cities. It has been shown that mobile device users have a higher level of interaction in public areas compared to non-digital users. Digital communication strengthens social ties among users in urban landscape areas and facilitates information sharing. Sharing user experiences via photos and videos boosts the promotion and usage of these areas. The Internet of Things (IoT) increases efficiency in managing urban landscape areas by providing remote data collection, storage, and sharing capabilities. These technologies foster safer and more accessible environments for users while supporting the sustainable management of natural resources. This study systematically evaluates how the integration of digital technologies can optimize the management of urban landscape areas and enhance user interactions. Additionally, it provides strategic approaches and recommendations for effectively integrating these technologies.

Keywords: Landscapes, Digitization, Interaction, IoT, Sustainability.

1. INTRODUCTION

The management and user interaction of urban landscape areas have gained critical importance in the context of increasing urban population and changing social needs. This study examines the integration of digital technologies in urban landscape areas, focusing on operations, accessibility, security, and user interactions.

Specifically, the advantages and disadvantages presented by technologies such as Wi-Fi, Geographic Information Systems (GIS), mobile applications, and the Internet of Things (IoT) in the management and user interactions of urban landscape areas are highlighted.

Digital Transformation in the Development of Urban Landscape Areas

The evolution of digital technologies has a significant impact in the urban landscape domain, affecting how cities are planned, designed, and managed. Digital communication in urban landscape areas strengthens social bonds among users and facilitates information sharing. Sharing experiences through photos and videos enhances the promotion and use of landscape areas.

Digital tools have had a significant effect on community building in urban landscape areas. They make it easier for people to share information and resources and organize events and activities that bring people together.

Smart city technology also plays a role in ensuring user safety. For instance, sensors and cameras can be used to detect and prevent crimes, while GPS tracking helps emergency teams quickly reach and assist those in need. Moreover, smart city technology helps manage traffic flow and reduce congestion, fostering a safer urban environment.

One of the most crucial digital security measures is cyber-security. It involves protecting computer systems, networks, and data from theft, damage, and unauthorized access. To ensure that users feel safe in urban areas, robust cybersecurity measures should be in place. This includes the use of firewalls, encryption, and multi-factor authentication.

Digital tools have revolutionarily changed how people interact with each other, especially in urban areas. Social media platforms and messaging applications have made it easier for people to connect regardless of their physical location. This has given rise to new models of social interaction built around digital tools. For example, virtual events and meetups allow people to connect without leaving their homes.

Digital transformation has enabled the urban landscape field to become more efficient, sustainable, and responsive to citizens' needs. By utilizing digital technologies like data analytics, IoT, and AI, urban planners and architects can gain insights into how people interact with their environments, allowing them to make informed decisions on how to design and manage cities.

2.1. Digital tools and social interaction models in urban landscape areas:

a. Socio-economic effects of wi-fi

Wi-Fi allows personal electronic devices to connect to the internet without a wired connection (Baker, 2016).

The proliferation of mobile technologies and the increased accessibility of Wi-Fi enhance user engagement and interaction in public spaces, thereby boosting the allure of cities. Mobile device users have a higher level of interaction in public spaces compared to non-digital users. Wi-Fi has become an integral part of modern life, with its impacts felt in various sectors, including education, health, and business. In urban areas, its effects are particularly noticeable, with various socio-economic implications being observed. Positive effects include:

- Increased connectivity and access to information lead to increased educational and employment opportunities.
- Improved communication and collaboration between individuals and businesses result in increased productivity and innovation.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Negative effects include:

- Increased reliance on technology can lead to potential health issues and social isolation.
- Unequal access to Wi-Fi leads to a digital divide, exacerbating existing social and economic inequalities.

Free public Wi-Fi has the potential to attract the public to urban landscape areas, including those looking to work, study, create content, or simply relax. Wi-Fi can also provide reliable communication in emergencies and when cellular networks are unavailable. However, public internet access should be securely protected and encrypted.

Contrary to concerns, digital communication in urban landscape areas doesn't necessarily hinder interaction among people. Instead, it can facilitate conversations about daily news, promote shared social activities, and allow users to share their experiences through photos and videos (Campbell & Kwak, 2011).

A study in 2010 introduced Wi-Fi services in seven major city parks in the US and Canada. Notable locations among these parks include Union Square in New York, Rittenhouse Square in Philadelphia, and Nathan Phillips Square in Toronto. The study found that:

- 25% of laptop owners had never visited these parks before Wi-Fi was introduced.
- 70% of those who had visited these parks before stated that they started visiting more frequently after the introduction of Wi-Fi.
- There were no negative effects observed from introducing Wi-Fi, meaning no users were deterred from visiting the parks because of it (Hampton, et al., 2010).

b. IoT and urban landscape areas

The Internet of Things (IoT) enhances efficiency in the management of urban landscape areas by allowing remote data collection, storage, and sharing. These technologies support sustainable management of natural resources while providing safer and more accessible environments for space users.

IoT technology has the potential to transform urban landscape areas by better managing resources and infrastructure. Some applications of IoT for urban sustainability include:

- Smart lighting systems that adjust based on human presence, resulting in energy savings.
- Smart waste management systems that optimize collection routes, reducing pollution.
- Smart transportation systems that reduce traffic congestion and improve air quality.

In 2014, as part of the "Padua Smart City" project in Padua, Italy, researchers from the University of Padua collaborated with Patavina Technologies. A sensor network consisting of 300 nodes was set up around the university area. These sensors, mounted on streetlights, measured temperature, humidity, and air quality. After a seven-day data collection period, it was observed that rainstorms led to a decrease in light intensity and temperature but an increase in air pollution and humidity. This indicated that rainstorms potentially increase traffic congestion, contributing to air pollution. This study demonstrates how different sensors can be used to determine the relationship between weather conditions and air quality (Zanella & Vangelista, 2014).

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

c. Mobile applications and urban landscape areas

Mobile applications can be used for various purposes related to urban landscape areas. They provide basic information about urban landscape areas, collect data, enhance the creation of educational and social media content, and facilitate collaboration and two-way communication between users and staff.

Mobile applications can provide users in urban areas with real-time information about local events, transportation, and other services, improving their overall experience.

Mobile apps can also be used to promote community engagement in urban areas. For example, apps allowing users to report issues like potholes and graffiti can help improve the overall appearance of the city. Additionally, apps providing information about local volunteer opportunities and community events can help foster a sense of community among city residents.

According to Klyde Warren Park (2015), the 5.2-acre Klyde Warren Park in Dallas collaborated with the tech firm Pariveda Solutions to develop a mobile app to provide real-time information about the park to visitors. Features of this app included a digital event map, program information, and menus for food trucks. Users were informed about event updates and program changes through the app. The application has received positive reviews on Google Play and has approximately 1,000 downloads. This suggests that the app particularly appeals to a specific audience who frequently visit the park, especially given that the park hosts approximately one million visitors annually.

d. Geographic information systems and services

Geographic Information Systems and Services (GIS) use digital software to capture, store, process, analyze, manage, and present geographic data. GIS mapping technology offers a high potential to structure the collection, analysis, and presentation of various data types that can be used to enhance the accessibility, environmental management, community engagement, health, and management of urban landscape areas. Comprehensive installation with sensor systems may require specialist and observer managers to act upon the collected data.

Between 2012-13, the Universities of Queensland and South Australia conducted research examining the effect of urban parks in Campbelltown, Adelaide, on physical activities. The study utilized an internet-based geographic information system to collect data from park users regarding their activities and benefits derived from the park. Participants provided information by marking their activities and benefits on a digital map. The collected data was visualized to provide insights into how parks were used and to be used for urban planning (Brown, et al., 2014).

3. Digital Transformation in Urban Areas Worldwide

- Smart Dubai is an extensive initiative aiming to transform Dubai into the world's smartest city. This effort leverages cutting-edge technologies such as artificial intelligence, blockchain, and the Internet of Things to enhance the city's infrastructure, services, and the quality of life of its citizens. Key projects under Smart Dubai include the Dubai Blockchain Strategy, Dubai Data Initiative, and Dubai Paperless Strategy. These initiatives have positioned Dubai as a global leader in smart city innovation and digital transformation.
- Barcelona Smart City is a program launched by the city of Barcelona to promote sustainable development and improve the quality of life of its citizens through technology.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

The program encompasses various ventures such as smart lighting, smart parking, and smart waste management. One of the primary projects under the Barcelona Smart City program is the Superblock project, which seeks to transform city streets into blocks made up of large vehicle-free zones, turning them into pedestrian-friendly areas. The project has successfully reduced traffic congestion and air pollution, while also promoting social interaction and community engagement.

- Singapore is a smart city with advanced transportation systems and green spaces.
- Masdar is an eco-friendly city with sustainable energy and water management systems.
- Songdo International Business District is a smart city equipped with an advanced information and communication technology infrastructure.

4. CONCLUSION

Today, with the widespread use of digital technologies, smartphones, and social media, combined with the availability and opportunities of Wi-Fi in public spaces, it is believed that the use of digital applications can enhance the appeal of public landscape areas. It has been observed that mobile device users tend to spend more time in public spaces compared to non-users. This could imply a higher likelihood of the public using mobile devices. Digital communication in public areas does not necessarily inhibit interaction between people. On the contrary, it can facilitate discussions about current events, encourage shared social activities, and enable park users to share their experiences through photos and videos.

Modern mobile devices and sensors are compatible with the Internet of Things (IoT), an electronic and software network. IoT allows communication between digital devices and enables remote collection, storage, and sharing of data over the Internet. It's crucial to consider the opportunities offered by these technologies and ponder how better services can be provided in urban landscape areas. At this juncture, it's essential to identify user needs and objectives, prioritize user experiences, and take accessibility into account.

Thanks and Information Note

ABSTRACT

Recently, people's return to nature has become an important focus of attention, with the concept of leisure time being valued and spent with quality. People that living in cities often turn to nature, which is outside of urban areas, to meet their outdoor recreational needs. Camping areas, which are among the outdoor recreation resources outside the city, have been in demand in recent years. It is a form of recreation carried out by making use of tents, caravan huts and similar accommodation tools in order to perform different recreational activities in nature, to rest or to stay for a short time. The landscape is at the heart of successful recreation and tourism. The unique beauty and uniqueness of a landscape closely affect its recreation and tourism attractiveness. Various existing camping areas on the shores of Lake Van within the borders of Van Province are used by those who prefer camping recreation, especially in summer. In this paper, the general characteristics of the Çakıl Island Camp Recreation area, which is one of the existing camp areas based on the coast, were evaluated. The importance of Çakıl Island, where many recreational activities such as camping, tents, caravans, daily visits and picnics are combined, makes it much different from other camping areas in terms of visual landscape quality. Solution suggestions have been made to ensure the sustainability of this camping area in line with the landscape values.

Keywords: Recreation, Camping Areas, Landscape, Sustainability, Çakıl Island.

1. INTRODUCTION

As a result of fulfilling people's different wishes and desires in terms of recreation in their spare time, different types of tourism have emerged today, and the return to nature and ecology has become a major focus of interest. According to Ryan (1991), camping activity, which is carried out in recreational areas today, has become increasingly popular in the world in recent years for reasons such as providing the opportunity to evaluate the opportunities of another natural environment at every opportunity and providing this with more economical conditions than other activities, and the fact that accommodation can be carried out in environments rich in natural and historical-cultural values. It has started to become a serious alternative to the holiday habit of owning or renting a holiday home or traveling to other countries.

The source of recreational activities carried out in nature is nature. Nature-based tourism activities are becoming increasingly popular around the world. Especially camping activities are the most preferred outdoor recreation activity by people (O'Neil et al., 2010). Camping is

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

an activity carried out by using caravans, tents, huts and similar accommodation devices for purposes such as engaging in recreational activities in nature, resting or staying for a short time (Topay and Koçan, 2009). The fact that the majority of working people can take leave during the summer months and that schools are closed during the summer months make the summer months the season when the demand for camping is at its peak (Sözen and Şahin, 1988). Forest areas, water and waterfronts have an important potential for people to relax, refresh their minds and have fun (Eminağaoğlu et al., 2016). People who try to take advantage of their weekend holidays, especially to get away from the crowded city environment and busy work schedule, prefer the close surroundings of water surfaces and natural green areas. It is a proven fact that water has relaxing properties. The most preferred rural recreation areas are the coastal areas of the sea, lake, dam lake, stream and dam ponds (Akten and Akten, 2011; Eminağaoğlu et al., 2016). Water, which is a landscape element that relaxes and relaxes people psychologically, allows many active recreation activities along with its spiritual effects (Altınöz et al., 2014). In accordance with the values they carry, these areas provide opportunities for many activities such as camping, picnics, trekking, bird watching, photo safari and landscape viewing (Demir, 2001). Therefore, coastal areas are very valuable resources that can meet recreational needs (Özdemir Işık and Demirel, 2016; Aşur, 2017). Coastal areas are important activity areas in terms of visual landscape value. It is a fundamental component of the natural environment in terms of recreation and tourism and affects the overall quality of recreational and touristic activities. In this context, it contributes significantly to the regional economy and the attractiveness of the environment (Clay and Daniel, 2000; Aşur and Alphan, 2018).

1.1. Campgrounds

Camping, a recreational activity, was common among the elite in the early 20th century. Over time, this activity has spread among other socioeconomic groups. Published in the Official Gazette No. 21728 dated 14.10.1993: "Campings in the Regulation on Tourism Investment and Enterprise Qualifications; "They are facilities with at least 30 units established on highway routes and their immediate surroundings, at city entrances, in places with natural beauty such as seas, lakes and mountains, and where tourists generally meet their needs for overnight stay, food and beverage, rest, entertainment and sports with their own means." It is of great importance to evaluate regional factors in campsite planning and design. A map containing information such as main highways, water surfaces, places with historical and cultural significance, natural areas of significant attraction and long walking paths will ensure that the proposed facility is in the right location. Vegetation is the biggest resource of campsites. It is better not to lose what was originally owned, to maintain it and to avoid damaging it, than to recreate it. For this reason, before starting planning, the existing vegetation of the study area should be shown on the current maps. When choosing camping areas, climate, soil characteristics, topographic structure and accessibility are qualities that must be taken into consideration. Since camping areas are located in open areas, they should be established in areas that do not receive much rainfall and are protected from strong winds. The topographic structure of the camping areas should be chosen in a very flat place to facilitate the setting up of tents and the movement of caravans. The slight slope of the camping area prevents tent and caravan users from being affected by rainwater.

According to Sözen and Şahin (1988), topographic slopes up to 5% are the most ideal slopes for roads, structures and campsites. Slopes between 5-15% can be chosen for playgrounds and camping areas, provided that terracing or leveling is done. The distance of camping areas to

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

main traffic roads is important for accessibility. In campsites established close to the main traffic network, long-term users as well as passers-by have the opportunity to spend the night in the camping area, which increases the usage capacity of the camping (Bulut, 2000). Apart from all these, the proximity of camping areas to green areas, other recreational activities and especially public service units such as water, electricity and telephone lines are factors that affect site selection (Güleç, 1990).

Coastal areas, which are open areas, are recreational areas where social interactions can be experienced with the trio of sun, sea and sand (Hall and Page, 2012). However, spatial changes occurring in coastal areas sometimes lead to the destruction of natural areas. There are outdoor recreation areas of various sizes in the coastal areas of the Van Lake Basin, allowing camping, picnics, trekking and swimming activities.

In this paper, the general landscape features and activities offered by the Çakıl Island Camp Recreation area, one of the existing coastal camping areas, were evaluated. The importance of the area was emphasized and suggestions were made to ensure its sustainability.

2. MATERIALS and METHODS

The main material of the study, Çakıl Island camping area, is located within the borders of Erciş district of Van Province (Figure 1).

The surface area of Van province, located in the Eastern Anatolia region, is 19,069 km². In the southern coastal region of Lake Van, the world's largest soda lake, in the Deveboynu Peninsula location, 38°26' and 38°29' Northern latitudes and 42°52', 42°47' Eastern longitudes and in the Mollakasım Settlement location, 38°42' and 38'. It is located between 36' North latitude and 43°11' and 43° 56' East longitudes. It is located in the closed basin of Lake Van in the Upper Murat-Van Section of the Eastern Anatolia Region. The coastline of Lake Van covers an area of approximately 430 kilometers, its deepest point is approximately 450 meters, and the lake surface is approximately 1,650 meters above sea level. Van has continental climate characteristics. Van's annual average temperature is 9°C, and while the average temperature in January, the coldest month of the year, can drop to -3.5°C, the average temperature in July, the hottest month, is 22°C. The total annual precipitation is approximately 400 mm, with 39% falling in spring, 27% in autumn, 26% in winter and 7% in summer. Snow cover can remain on the ground for approximately 90 days of the year. Van is one of the regions that receive the most sun in the country (Anonymous, 2023).

Figure 1. Location of the study area.

The method of the study is based on the literature review on the subject and the evaluation of the obtained data for the purpose of preserving and increasing the recreational usability of the area. In addition, in order to indicate the natural landscape features of the area and the uses in the area, on-site inspections, observations and measurements were made, photographs and videos were taken, and the current situation was analyzed and determined. In addition, the opinions of the people of the region, the people in the area and the operator were taken to determine their opinions about the recreational camping activity, the points they are hesitant about and the points they would support. Relevant factors that will be effective have been selected to determine the suitability of areas where recreational camping activities can be held. These; natural factors, socio-cultural factors and visual landscape factors. Accordingly, the suitability of the camping area was evaluated and interpreted, and improvement suggestions were developed.

3. FINDINGS and DISCUSSION

Çakıl Island camping area; It is located in Bayramlı village of Erciş district of Van province. The camping area is built on a small peninsula formed by white pebbles carried by the waves in an area of 18,000 m², which emerged as a result of a natural formation. This area, with an altitude of 1654m, has been operated by the people who own the land closest to the coastline

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

since 2015. Çakıl Island can be defined as an area of very high visual landscape value, connected to the mainland by narrow gravel accumulation shapes called Tombolo or Saplı Island (Figure 2). It is said among the local people that the area was used as a natural harbor in the 19th century and the grapes grown in the surrounding villages were used to make wine, traveling from here to Tatvan and then to Italy.

Figure 2. Satellite image of Çakıl Island camping area.

Recreational Water Use Bacteriological lake water samples are taken from the swimming areas determined by the Swimming and Recreation Commission in the center of Van and the districts bordering Van Lake, at the frequencies specified by the regulation during the swimming season, between 15 June and 15 September, and are analyzed in the Van Public Health Laboratory, and the results are analyzed in the Van Public Health Laboratory. It is recorded in the Health Institution's bathing water quality system. The classification report for 2021 is included in Table 1.

Table 1. Çakıl Island beach bathing water quality

Year	District Name	Swimming Area	National Classification Result	Compliance with Mandatory Value	Activity status
2021	Erciş	Çelebibağı Çakıl Island Beach	A	Suitable	Aktive

(A: Very good/Excellent quality - B: Good quality - C: Medium quality - D: Poor quality) Reference: (Van Provincial Directorate of Health, 2022).

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

The interpretation of the factors considered as a result of on-site analysis and observation of the area is given below. These factors are: Natural factors, Socio-cultural factors and Visual Landscape Factors.

In terms of natural factors, the region is under the influence of the continental climate and the tendency to camp is more frequent in the summer months. The hill located in the northern part of the area is covered with heavy snow during the winter months and there is a possible avalanche danger. Due to the lack of adequate afforestation on the hill, which is approximately 50-60 meters high in the north direction, there is a slight risk of landslides. Tectonic movements and volcanic activities occurring at the bottom of the Van Lake Basin were effective in the formation of the island. The camping area has a slope of 6%.

The camping area faces south, which is a suitable aspect. According to the land registry and cadastre directorate parcel inquiry with the access date of 02.04.2023, the natural formation where the island is located is an unregistered public area. The presence of a wetland with an interesting natural formation in the central part of this peninsula has provided a characteristic landscape for Çakıl Island (Figure 3).

Figure 3. Çakıl Island campsite (Original).

In terms of socio-cultural factors, it is 121 km away from Van center. Transportation to the area is via a poorly maintained dirt road, 119 km of which is asphalt and the remaining 2 km. Transportation to the island, which is 17 km away from Erciş, is possible by private vehicle. 15.4 km away is Erçiş Çelebi Bağları Family Health Center No. 2. Security measures provided by the business in the area are provided during the summer months. The existence of a camera system belonging to the business and the accommodation of the business owners in their nearby houses during the summer do not pose any security risk. In terms of adequate infrastructure, there is an infrastructure system such as electricity, toilet, shower, drinking water and potable water. Although it has a very special natural landscape feature, it has not reached a sufficient level of awareness about the area. Negative human impacts: Thanks to the intense supervision, control and maintenance of the business, it is not possible to talk about the negative impact that those who come to the area have on the environment. In terms of swimmability, clean water and swimming suitability are high. In terms of Facility Availability, the private enterprise offers market, cafe, toilet, shower, parking lot, umbrellas, sun loungers and tent camping areas for general needs. Tent and caravan camping is also possible in the available and quieter area of

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

the beach. There are 50 portable pergolas and tents in the area, which can be disassembled and assembled by a private operator (Figure 4 and Figure 5).

Figure 4. Beach volleyball court at Çakıl Island camping area (Original).

Figure 5. Çakıl Island camping area beach (Original).

In terms of Visual Landscape Factors, the water of the shore of the camping area has a very transparent and clean appearance in terms of water quality. Planting was done by the company in the immediate surroundings of the area. There is no negative adjacent view in the area. There is variable surface relief in the immediate vicinity of the area. Although the camping area has unique panoramic views, the small wetland located in the middle of the area adds a different and characteristic visual quality to this camping area (Figure 6).

4. CONCLUSION and RECOMMENDATIONS

Tourism activities are increasing day by day around the world, and with this increase, an increase in tourism types is also noticed. For travelers looking for a difference and those who want to engage in alternative tourism activities, specially organized businesses have begun to increase in the service sector. People who are away from nature in big cities and are looking for a quiet environment have started to prefer areas where camping can be done.

This study was based on the Çakıl Island camp sample area, located on the shores of Lake Van, where the natural landscape values where land and water meet are synthesized. It is of great importance to fully preserve the unique resource values of Çakıl Island and to pass them on to future generations. Common problems experienced in other tourism and recreation areas in Turkey, such as administrative, legal, environmental, educational and economic, are also seen in this area. The most important issue that should be taken into consideration in order to ensure the sustainability of such recreation areas should be to preserve the resource values and transfer them to future generations with the understanding of protection of the natural environment. All activities and arrangements to be made in the Çakıl Island Camping area should be within the framework of this understanding. Instead of dominating nature, an approach that aims to be in harmony with nature and tries to benefit from it should be adopted.

Suggestions that will contribute to the protection and sustainability of this coastal recreational camping area are listed below:

- The shorter connection between the vehicle road and the beach will positively affect the increase in recreational uses of this camping area.
- In Çakıl Island, where the infrastructure problems have been relatively solved, tented areas are insufficient due to the high demand in the summer months. In this case, the inadequacy of infrastructure and superstructure facilities must be eliminated.
- The management of Çakıl Island and similar areas with unique landscapes should be done by experts in their fields.
- Since the best observer of an area is its user, one-on-one interviews should be held with the users of the area to be managed.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

- Vegetative strengthening of the areas close to the area will improve the coastline ecologically and increase recreational uses.
- Another issue to be taken into consideration in distributing the visits to the area throughout the year is the development of a recreational management policy to establish a delicate balance between the protection of the area and the continuation of its recreational use. In line with this policy, it would be correct to first determine the visitor profile of the area by relevant institutions and organizations.

In order to ensure the protection and sustainability of areas that are important for tourism and recreation, such as Çakıl Island, it is not correct to completely isolate this area from people. Considering that visits peak in certain periods, it is important to ensure that carrying capacities are not exceeded. The increase in the number of visitors is a positive development in the context of increasing recognition of the area and its ability to serve recreational activities. However, it would be better to spread the periods with the highest number of visitors to other suitable periods of the year as much as possible. Due to the climate characteristics of the area, the fact that the season is shorter than other touristic places with a hot climate negatively affects the tourism revenues of the region. Therefore, diversifying recreational activities to extend the season may be a solution.

ABSTRACT

Nowadays, natural areas attract more attention than before, due to the increasing population, apartment lifestyle and the physical condition of cities being away from naturalness. Landscape is undoubtedly one of the components that affect the attractiveness, identity and sustainability of natural areas as a place of connection between urban people and nature. Examining assessments of expert preferences for the visual quality of the landscape can play an important role in identifying existing landscapes with different visual value in order to preserve and regulate the condition of natural areas. In this study, it is aimed to evaluate the visual preferences of Emre Lake, which is a natural lake in the town of Döğër, İhsaniye district of Afyonkarahisar province, within the scope of biophysical landscape interactions, according to experts. Photographs of the area in expert evaluation; It was presented with questions with nine parameters: Naturalness, Worth of Protection, Diversity, Originality, Mystery, Inviting, Exciting, Impressive, Safety, Relaxing. According to the results obtained, in the direction of the landscape values of this lake, it has been tried to be discussed in the future for recreational purposes together with protection.

Keywords: Emre Lake, Expert Evaluation, Landscape Features

1. INTRODUCTION

The visual quality of the landscape is evaluated by perception and preference, the human eye and judgment. However, human judgment is often categorized as citizen versus expert. Literature reviews show that expert-based evaluation prevails over citizen-level judgment. It is possible to talk about the lack of information about methodologies to evaluate public preference of landscape and landscape qualities (Nakarmi et al. 2023).

Because landscape means different things to people depending on context and background (Antrop, 2005; Griffiths, 2018), perspectives on and preference for landscape vary greatly, and there is no universally accepted theory for landscape aesthetics (Kaymaz, 2012).

The use of photographs rather than in situ imaging of landscapes has been a widely accepted approach to assessing public preference for several years (Nakarmi et al. 2023).

The human perspective on land resources has been recognized not only as a piece of land providing food and shelter, but also as a visual resource for aesthetic, scenic and recreational values since the mid-nineteenth century. Since then, setting aside the best and unique landforms and landscapes for conservation and recreation has begun by designating areas such as national parks, reserves, areas of outstanding beauty and wild areas (Dmytrowski and Kicińska, 2022).

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium **September 14-15, 2023, Naples, Italy**

The two main philosophies, objective and subjective, have been widely discussed, especially in the field of visual quality assessment of landscapes (Brooks and Lavigne, 1985). In objective philosophy, we focus on the biophysical aspects of the landscape and its characteristics such as form, shape, texture, color, liveliness, originality, pattern, etc. importance is given to its beauty from different angles (Daniel, 2001). "Biophysical landscape interactions are biotic and abiotic processes that have an impact on developments in and evolution of a landscape" (van der Ploeg et al. 2018). Both of these beauty philosophies are equally important. However, the objective philosophy has dominated landscape assessments and studies for several years compared to subjective or user-centered landscape assessments (Kvan, 2013).

Landscape preference depends on what the landscape offers (Gibson, 1979; Herzog, 1987). Affordances are "features and configurations" of landscapes. The higher the positive objectivity or beauty of the landscape, the greater the subjectivity or preference of the landscape (Peng and Han, 2018). This is information that is important for landscape planning and development.

The subjective aspect of the landscape "can be measured objectively by examining people's likes and dislikes, that is, their aesthetic preferences" (Lothian, 2017). Landscape assessment, planning and evaluation depend largely on human judgment. However, human judgment is often discussed broadly from expert and citizen perspectives (Daniel, 2001). Often, the expert's judgment is based on training and experience. It mostly lacks psychophysical aspects (Liu et al. 2018). Expert sovereignty generally involves objective resource assessment and often focuses on scientific, ecological, and physical aspects of the landscape (Liu et al. 2018). Citizen opinion is a perception-based approach where neither education nor experience and standards or frameworks are required (Daniel, 2001). Herzog et al. (1982) noted the many ways in which "citizens' perceptions and preferences differ from those of planners/experts." Daniel (2001) found that perceptions vary greatly from person to person, noting inconsistencies of opinion even among experts for the same landscape.

In Turkey, as in the rest of the world, natural areas have begun to be destroyed, a rapid change has occurred in the landscape, and concrete cities have begun to form (Akten, 2003; Yılmaz et al., 2009).

In this study, the evaluation of visual and aesthetic preferences according to experts within the scope of the biophysical landscape qualities of Lake Emre, a natural lake in İhsaniye district of Afyonkarahisar province, is discussed.

The main material of the study consists of Lake Emre, which is located as a natural lake in Döğler town of İhsaniye district of Afyonkarahisar province. Emre Lake, located between Döğler Town and Bayramaliler Village, is a lake formed by natural means.

The photo survey method is one of the most direct approaches to assessing visual quality in rural landscapes (Arriaza et al., 2004; Aşur, 2022). Photographic survey visually demonstrates the natural beauty of the landscape and allows the observer to evaluate the aesthetic appeal of the landscape. To determine the landscape value of the area, 9 parameters determined and 14 images selected from photographs taken from this area were used together to obtain expert opinions. Questions and photo scoring are both simple and straightforward methods for assessing expert preferences of landscapes and landscape features. In the study, 14 photographs of the area were selected based on visual indicators such as naturalness, worth protecting, diversity, originality, mysteriousness, inviting, exciting, impressive, safe, relaxing, which

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

define the visual characteristics of the landscape, landscape preferences and experience theories. A survey was prepared to determine the criteria that experts consider when evaluating the visual quality of the landscape. These images were scored in 3 categories: high, medium and low in terms of landscape value. Using studies on this subject (Yeomans, 1983; Aşur and Alp, 2020), the scoring system was interpreted by 10 experts as 10-8 as good, 7-4 as medium, 3-1 as bad. A scoring table was created by taking the arithmetic average of the scores given, and the scores were revealed on the scale determined according to the visual landscape quality assessment of the area.

1.1. History and Features of Lake Emre

Within the borders of the cities of Afyonkarahisar, Eskişehir and Kütahya, the history dates back to B.C. It is located in the Phrygian Valley, which dates back to 750. Emre Lake is located within the borders of Döğer town of İhsaniye district and the 3000-year-old Phrygian Valley, approximately 50 km away from Afyon. The surface area of the lake is approximately 5 km² and its depth is over 3 m in some areas. Due to its geological structure, the Phrygian Valley has been the settlement of many different civilizations throughout history. As a result of the carving of the rocks, settlements and mausoleums were formed. It also attracts the attention of freshwater fishermen. The fact that the bottom of many parts of the lake is grassy creates suitable living conditions for fish, allowing them to live and feed comfortably. It is one of the places frequented by some migratory birds, especially pelicans, in April and May. Their collective movements on the lake during hunting times attract attention and are worth seeing (Anonymous 1, 2023). You can reach Emre Lake, which is 30 km away from the Gazlıgöl region, via the Gazlıgöl-İhsaniye-Döğer road route or the Gazlıgöl-Yaylabağı-Demirli-Bayramaliler road route (Anonymous 2, 2023).

2. MATERIALS and METHODS

The main material of the study consists of Lake Emre, which is located as a natural lake in Döğer town of İhsaniye district of Afyonkarahisar province. Lake Emre, located between Döğer town and Bayramaliler Village, is a lake formed by natural means (Figure 1).

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

High, medium and low categories emerged as a result of the scores given to the parameters of naturalness, worth protecting, diversity, originality, mysteriousness, inviting, exciting, impressive, safe and relaxing, which are based on visual indicators related to the landscape of the area. The result of this evaluation is given in Table 2 based on the percentage system.

Table 2. Percentage values of landscape features as a result of scoring

Parameters	Parameters Visual Quality Degrees		
	High (8-10)	Medium (4-7)	Low (1-3)
Naturalness	%20	%80	%0
Being Worth Protecting	%80	%20	%0
Variation	%20	%20	%60
Originality	%20	%80	%0
Mysteriousness	%40	%60	%0
Inviting	%20	%80	%0
Excitingness	%80	%20	%0
Impressiveness	%60	%30	%10
Security	%40	%50	%10
Relaxing	%80	%20	%0

Based on the findings of the study, this field is of high value to experts, with a rate of 80% being deemed worthy of protection and having an exciting and relaxing effect. However, it was found moderately natural, original and inviting by 80%. It was also revealed that this area has a low value in terms of diversity, with a rate of 60%.

4. CONCLUSION and RECOMMENDATIONS

Nowadays, people are turning to rural areas, forests, waterfronts and protected areas around cities in order to meet their recreational needs in natural areas, away from the crowds of busy cities. Visual quality assessment of the landscape is used as a guiding tool that is important in the planning and design of rural and urban environments and in the formation of some managerial policies, in the context of the visual data it produces about the changes in the physical environment.

Within the scope of this study, based on the data obtained from the research findings, the visual evaluation of the landscape components of Lake Emre in Afyonkarahisar depending on different land cover was presented and correlated with their preference status. In general, literature studies have revealed that the preference of experts increases with the increase in the degree of naturalness and unique cultural characteristics in landscape scenes.

Naturalness has a strong influence on landscape preferences. Relevant stakeholders should take into consideration that Lake Emre should be worth protecting due to its natural and cultural landscape features. The fact that the naturalness of this area has a moderate value indicates that recreational uses are probably being used without considering the naturalness of the area and that the nature of the area is not paid enough attention in the landscaping works. Likewise, the low value of diversity in the study area indicates that care should be taken to ensure diversity in landscaping works to be carried out in order to provide recreational opportunities in the future.

According to the scoring study, it will help determine how the area will not lose its value in the future through conservation and recreational work. This study is a preliminary study on the landscape values of Lake Emre and its immediate surroundings. Therefore, it is recommended that more detailed and comprehensive studies should be conducted in this field in the future.

ABSTRACT

Urban spaces that occupy little space on the Earth's surface are also a source of significant environmental problems. The reasons for this are shown to be urban planning and designs made without considering natural data to meet the needs of the increasing population. In this research, the settlement areas of Erzurum, an important winter tourism city in Eastern Anatolia, established at a high altitude, were analyzed in terms of thermal comfort. The city center, which constitutes the historical core, and the settlements opened for settlement, especially after the 1980s, such as Yenişehir, Dadaşkent, Şükrüpaşa, and Yıldızkent, were examined. Within the scope of the study, the historical core that includes traditional buildings and the new modern construction were compared in terms of thermal comfort. In the areas where the study was conducted, the "Davis Vantage Pro Plus" meteorology tool was installed at a height of 1.5 m, and hourly data was recorded throughout the year 2022. The PET values were calculated by analyzing the obtained data with the RayMan Pro 2.1 computer software. The lowest PET value measured during the year was -7.5°C for the historical core in January, -9.8°C for Yıldızkent, -10.9°C for Dadaşkent, -10.7°C for Şükrüpaşa, and -10.6°C for Yenişehir. In the hottest month, August, the PET values were 24.8°C for the historical core, 23.4°C for Yıldızkent, 22.8°C for Dadaşkent, 22.9°C for Yenişehir, and 22.5°C for Şükrüpaşa. According to measurements in the month of July, historic core and its surroundings were measured to be 2.3°C hotter in terms of PET values compared to newly settled areas. The use of data obtained in physical planning decisions is crucial for sustainable urbanization.

Keywords: New Residential Area, PET, Cold Region, Settlement.

1. INTRODUCTION

It is estimated that the urban population will continue to increase and reach 6.4 billion by the year 2050 (UN, 2019). This implies more housing, impermeable surfaces, and less open-green spaces in urban areas. It is essential to determine new settlement locations and consider the characteristics of urban climate during the planning and design phases in this process. Adapting to these changes and using spatial planning as a tool is seen as a necessity for cities to minimize the adverse effects of climate change and become sustainable (Carter et al., 2015).

Around the world, outdoor thermal comfort studies are conducted using various climate modeling software. Despite the numerous software models used in thermal comfort studies,

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

RayMan pro 2.1 is the most commonly used in urban design studies (Potchter et al., 2018). The values obtained in the calculations for Physiologically Equivalent Temperature (PET), which is used in outdoor thermal comfort studies, are typically in degrees Celsius ($^{\circ}\text{C}$).

In cities with high living standards worldwide, hourly meteorological data obtained from devices located within the city are often used in planning (Stuttgart-Germany; Singapore). Especially, wind speed and direction within the city, street width, orientation, presence of vegetation, and building height variation depend on factors such as (Qaid et al., 2016; Kotharkar and Bagade, 2018; Yilmaz et al., 2022). According to a study conducted in Beijing, China, it has been observed that the presence of urban green spaces leads to increased PET values and positively affects thermal comfort. The most suitable time frame for city residents was reported to be between 2:00 PM and 3:00 PM (Sun et al., 2017). In a thermal comfort study based on urban forms in Egypt, it was found that there could be a temperature difference of 9.0°C depending on the building block characteristics. The study emphasized the influence of residential block forms and street canyon features on thermal comfort, but it also highlighted the need for such studies in various areas (Galal et al., 2020). It was noted that the results vary according to the topographical structure of the area where the city is located, with surface temperature studies being conducted mainly in flat areas (Goa et al., 2020). In terms of building layout, it was determined that in areas with high density and multi-story buildings, the land surface temperature (LST) increases in the city center (Li et al., 2012; Yang et al., 2018). On the other hand, in areas with low building density and a high ground area ratio, which means an abundance of open spaces, low LST values were identified (Yin et al., 2018).

In Erzurum, where the climate negatively affects living conditions, especially in the winter months, determining thermal comfort values in new settlement areas and raising awareness for urban renewal areas have been considered crucial. Therefore, in Erzurum, four different areas with dense residential structures that have been opened for settlement, especially after the 1980s, and are located in the city's development axes, have been designated as study areas. The aim is to determine the outdoor thermal comfort values of these residential areas.

2. MATERIAL and METHOD

2.1 Material

This study will be an original research project for cold climate regions both worldwide and in Turkey. Erzurum city, which has a significant 600-hectare urban renewal and transformation area and is on its way to becoming a prominent winter city brand, was chosen as the pilot region. The city is located in the northeast of the Eastern Anatolia Region, between $40^{\circ}15'$ and $42^{\circ}35'$ east longitudes, and $40^{\circ}57'$ and $39^{\circ}10'$ north latitudes, covering an area of 25,066 km². The city is surrounded by high mountains and has a basin-like topography. The elevation of the settlement area is approximately between 1800-2000 meters above sea level. According to data obtained by the State Meteorological Affairs over many years, the coldest monthly average in the city is -13.9°C , the hottest monthly average is 27.1°C , the lowest temperature recorded in December is -37.2°C , and the highest temperature in August is 36.5°C . The annual precipitation is 431 mm, with 50 days of snowfall and a snow cover duration of 114 days (Anonymous, 2020).

Within the scope of the research, four stations symbolizing different new urban settlement areas and housing structure uses in Erzurum are provided below in order. The locations of these

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

stations are shown in Figure 1. The "Vantage Pro2 weather station device" was installed and calibrated at the research sites and placed within protective cages. The data recording device was placed near the nearest public unit, where it could be plugged into an outlet.

Station 1 - Dadaşkent Station: Distance from the city center is approximately 7.9 km.

Station 2 - Yıldızkent Station: This station is approximately 4.5 km away from the city center.

Station 3 - Yenişehir Station: It is located approximately 3 km away from the city center.

Station 4 - Şükrüpaşa Station: It is approximately 2.8 km away.

Figure 1. Location map of the study area and the positions of the stations: 1) Dadaşkent Station; 2) Yıldızkent Station; 3) Yenişehir Station; 4) Şükrüpaşa Station and meteorological measurement device.

2.2. Metod

Physiologically Equivalent Temperature (PET) = Fiziksel Eşdeğer Sıcaklık (FES): Bioclimatic comfort refers to microclimatic conditions in which humans adapt to their surroundings with minimal energy expenditure, feeling extremely healthy and dynamic (Fanger, 1970; ASHRAE, 1992; Blazejczyk, 1994; VDI, 1998; WMO, 1999; Matzarakis et al., 1999; Höppe, 2002; Matzarakis et al., 2000; 2007).

Thermal comfort values were prepared using the RayMan Pro 2.1 model. The PET index is derived from the equivalence of human thermal energy, making it an ideal tool when defining the thermal comfort range for different climate types (Matzarakis, 1999; Rudel et al., 2007). This index was developed primarily for outdoor spaces based on the Munich Energy Model for Individuals (MEMI) (Fanger, 1970; VDI, 1998; Höppe, 1999).

The environmental characteristics of the space where comfort values are calculated are as follows: Temperature = Average temperature: $T_a = T_{mrt} = ^\circ\text{C}$; Wind speed: $v = 0.1 \text{ m/s}$; Relative humidity: $\text{RH} = \%$; Solar radiation: W/m^2 ; Vapor pressure: $\text{VP} = 12.0 \text{ hPa}$; Cloud cover: $N = \text{Octas}$ (Mayer and Höppe, 1987; Matzarakis et al., 1999; Höppe, 1999; Matzarakis and Amelung, 2008).

Microclimate data obtained from all stations throughout the year 2022 were analyzed using RayMan Pro 2.1 to prepare graphs of PET, temperature, humidity, and wind data.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

3. FINDINGS and DISCUSSION

The thermal comfort status of these four settlement areas in Erzurum, which were opened for settlement, especially after the 1980s, and have a dense residential structure, has been examined. Microclimate data recorded on an hourly basis throughout the year 2022 were analyzed in sequence. The analysis graph for temperature is provided in Figure 2, the wind analysis in Figure 3, humidity conditions in Figure 4, and PET values graph in Figure 5.

Figure 2. Temperature graph for the four stations in the study area by month in the year 2022

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Figure 5. PET graph for the four stations in the study area by month in the year 2022

The PET (Physiologically Equivalent Temperature) frequency analysis graphs obtained from the analysis conducted with RayMan Pro 2.1 for the four stations in the study area for the year 2022 are presented in Figure 6.

The temperature data for the four stations in the study area were analyzed. In the assessment for the winter months, the minimum temperature value was determined to be -22.4°C in Dadaşkent residential area in January. Following this, Şükrüpaşa recorded -20.5°C , Yenişehir -18.2°C , and Yıldızkent -18.10°C . For the summer months, the highest maximum temperature value was recorded as 33.7°C in the Dadaşkent residential area in July. The maximum temperature data for July was 33.20°C for Şükrüpaşa, 32.70°C for Yenişehir, and 32.60°C for Yıldızkent.

According to the wind analysis values, the highest wind speed was determined to be in March for all stations. Among the stations, the maximum wind speed was found to be 6.3 m/s at the Şükrüpaşa station. Dadaşkent station also had its highest wind speed at 5.8 m/s in March. For the Yıldızkent station, the maximum wind speed of 4.5 m/s was measured in April. This value was recorded as 5.4 m/s for the Yenişehir station, also in April. Overall, it was observed that wind speeds are lower in winter.

In the analysis based on humidity values, values above 90% RH were observed in March, April, June, October, November, and December for all stations. Throughout the year 2022, the lowest humidity rate, ranging from 5% to 7% RH, was encountered in August for all stations. In terms of annual humidity data, the highest values were recorded in Dadaşkent, followed by the Yenişehir station. The Dadaşkent station has the lowest elevation among the stations, and the basin-like terrain with a high water table in this area has supported high humidity levels.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

According to the PET analysis data, the months of June, July, and August were identified as the most ideal for thermal comfort, with temperatures ranging from 18 to 23°C for all stations. The coldest stress was experienced at Dadaşkent station with a minimum of -28.9°C, while the heat stress was also attributed to the same station with 40.0°C in September. It was determined that heat stress occurred in all stations in August and September. In December, the lowest cold stress was -2.2°C, recorded at the Şükripaşa station. Overall, based on average PET values, it was found that Dadaşkent was the settlement area most exposed to cold stress. In this study area, which shows a planned development axis towards the west of the city, the high water table, the open plain nature of the surroundings, and the presence of low-rise buildings support cold stress (Yilmaz et al., 2022).

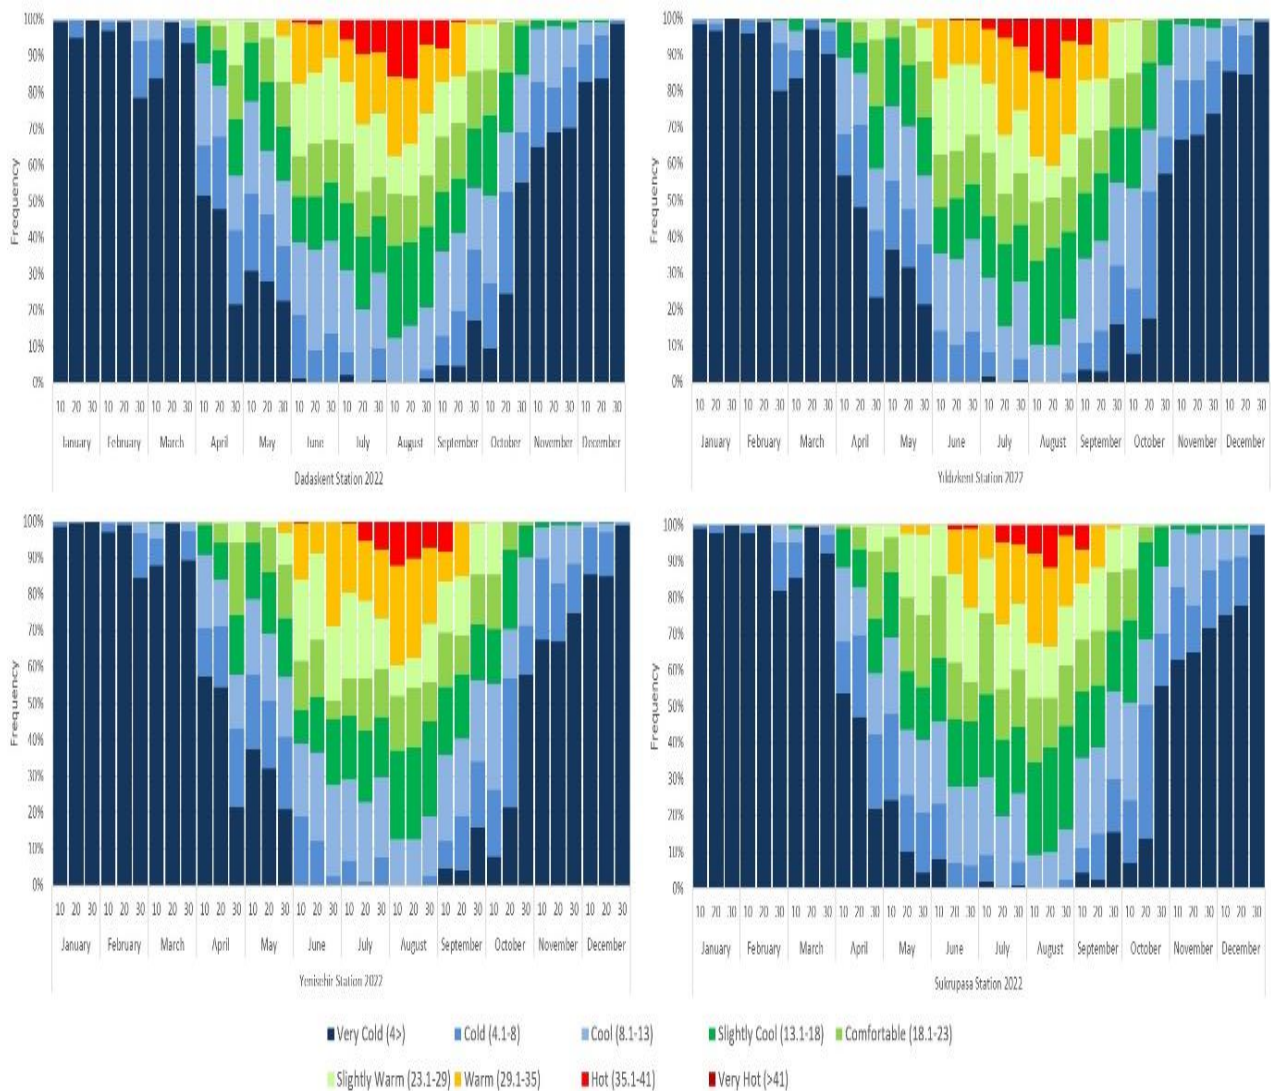

Figure 6. PET (Physiologically Equivalent Temperature) frequency analysis conducted for the stations by month.

4. CONCLUSION and RECOMMENDATIONS

In recent years, there has been increasing talk about energy-efficient, ecologically-based, sustainable, and more livable urbanization. To achieve this, it is envisaged that the natural and

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

cultural resource values of the region should be identified at a micro-scale in spatial planning and used in line with the opinions of the public. Activities aimed at establishing these standards in cities are supported by local governments and relevant ministries, and efforts are being made in this field.

In Turkey, urban transformation and renewal projects are taking place in almost every province. These projects can be turned into an advantage by listening to nature and focusing on climate and microclimate-oriented planning. The need to increase residential areas to meet the growing population demand has brought about environmental issues such as impermeable surfaces and a decrease in open-green spaces. The results of the analysis have shown that it is possible to improve thermal comfort in spaces planned to be in harmony with nature. When determining new settlement areas, the natural and cultural characteristics of the area under study must be taken into account within the framework of the sustainability principle. It is generally challenging to create thermal comfort conditions in flat, open areas with high water tables and agricultural potential.

Thanks and Information Note

Authors present their special thanks to "Scientific and Technological Research Council of Turkey, TÜBİTAK under Project No: 119O479" and Turkish State Meteorological Service (MGM) for sharing their data free of charge.

ABSTRACT

The key to designing a sustainable urban environment is to develop climate adaptation strategies and produce climate projections for the future. Erzurum holds an important place among winter cities for winter tourism. The city, located at an altitude of approximately 1800 meters, experiences long and snowy winters. This study was conducted to determine the effect of green areas on thermal comfort. The Ata Botanic Garden, which is rich in green areas in Erzurum, the residential area in the city center, and an area symbolizing the rural area outside the city were determined as the study areas. A "Davis Vantage Pro 2 Plus" meteorological measurement device was installed in these study areas. The RayMan Pro 2.1 model was used for thermal comfort calculations based on the hourly data obtained. A Physiologically Equivalent Temperature (PET) analysis for the year 2022 was conducted for the green areas, city center, and rural area, based on measurements taken from green areas and the city center. In the analysis of the data, PET values were determined to be -7.5°C in the city center, -8.1°C in the Ata Botanic Garden, and -14.7°C in the station symbolizing the rural area in January. In August, the hottest month for the city, the highest PET value was found to be 24.8 °C for the city center, 23.5 °C for the green areas, and 18.9 °C for the rural area. In terms of average PET values between the city and the countryside, a difference of 5.9 °C in August and 7.2 °C in January was obtained. It has been determined that the most important factor affecting this difference is the wind. This park, which has dense green areas, has been identified as 1.3°C degrees cooler compared to the city center. The data obtained from this study will contribute to making more accurate decisions in determining healthy urbanization, transformation areas, or new settlements. Locating cities in comfortable areas, developing them towards these areas, or increasing comfort in low-comfort areas through interventions will improve livability standards in cities.

Keywords: Thermal Comfort, PET, Urban Microclimate, Urban Green Spaces.

1. INTRODUCTION

Green areas are among the most important components that add value to urban areas with their aesthetic and functional contributions. In urban areas, green spaces fulfill many functions such as increasing humidity, cooling the air, producing oxygen and clean air, filtering suspended particulate matter, energy savings, reducing or redirecting wind, and reducing noise (Walker 1991; Bradshaw et al. 1995; Aslanboğa 2002; Trowbridge and Bassuk 2004; Barış 2005; Yu

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

and Hien 2006; Gill et al. 2007; Nowak and Dwyer 2000; Yılmaz et al. 2007a, b; Gómez-Munoz et al. 2010; Leuzinger et al. 2010).

One of the most prominent features of green areas in urban areas, which has recently attracted attention and has been the subject of numerous scientific studies, is their positive impact on thermal comfort and urban microclimates. Studies emphasize that thermal comfort in green areas is better compared to urban spaces (Shashua-Bar, Hoffman, 2000; Hendel et al. 2017).

Green areas, especially wooded areas, reflect a significant portion of short-wave radiation from the sun and absorb some of it, partially preventing the atmosphere from overheating during the summer months (Kayhan, 2007). This results in more comfortable areas compared to their surroundings during the winter months due to the absorbed heat (Yılmaz et al., 2019).

It is known that plants contribute positively to urban microclimates, especially through functions such as transpiration, reflecting sunlight, retaining heat on plant surfaces, shading, and reducing/directing wind. Plants largely obtain the energy they need to perform transpiration functions from the surrounding environment, creating a cooler area around the plant. Solar energy, when it hits objects, turns into heat. Plants reflect a portion of this solar energy, sending it into the atmosphere without turning into heat. They also retain some of it on leaf and branch surfaces. This provides shading and keeps the lower parts of the plant cool. The impact of plants on microclimate through their leaves is shown in Figure 1. The wind reduction and directing capabilities of plants can also have positive or negative effects on urban microclimates. When densely used, reducing wind speed can lead to an increase in temperature, while strategically designed plants, such as wind corridors, can positively affect thermal comfort in hot climates or during hot periods (Hsieh et al. 2016; Kong et al. 2017).

This study was conducted to determine the effect of green areas on thermal comfort. The study areas were determined as the Ata Botanical Garden, which has abundant green areas in Erzurum, an area symbolizing the residential area in the city center, and a rural area near the city center.

2. MATERIALS and METHODS

The study was conducted in the city center of Erzurum. In the study, which evaluated 12-month data for temperature, humidity, wind, cloudiness, and PET (Physiological Equivalent Temperature) for the year 2022, fixed stations located in Ata Botanical Garden, where there are abundant green areas in the city center of Erzurum, the residential area in the city center, and the rural area near the city center were used.

Erzurum, where the study was conducted, consists of three central districts (Yakutiye, Aziziye, and Palandöken) and has a total population of approximately 428,000 (TÜİK, 2022). The city center of Erzurum, which is at an elevation of approximately 1800 meters, is one of Turkey's most extreme centers in terms of climate values. According to the data obtained by the General Directorate of Meteorology for the years 1991-2020, the city's average temperature is 5.3°C, the annual average rainfall is 396 mm, the lowest temperature is -37.2°C, and the highest temperature is 36.5°C. The highest temperatures are recorded in July and August, while the lowest temperatures are recorded in January, February, and December. The duration of snow cover in Erzurum averages 110 days, and the average number of snowy days is 50. The average number of frosty days in the province is approximately 180 days, and the average number of clear-sky days is around 125 days. According to averages, the wind speed in the city is 2.7 m/s,

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

and in the winter months, especially, the wind speed and the number of windy days decrease significantly due to the city being surrounded by mountains (MGM, 2022).

In this study, data was collected from three different areas with distinct characteristics in the city center of Erzurum using 2 fixed meteorological stations and 1 station operated by the State Meteorological Affairs General Directorate. The study area and the distribution of the stations can be seen in Figure 1.

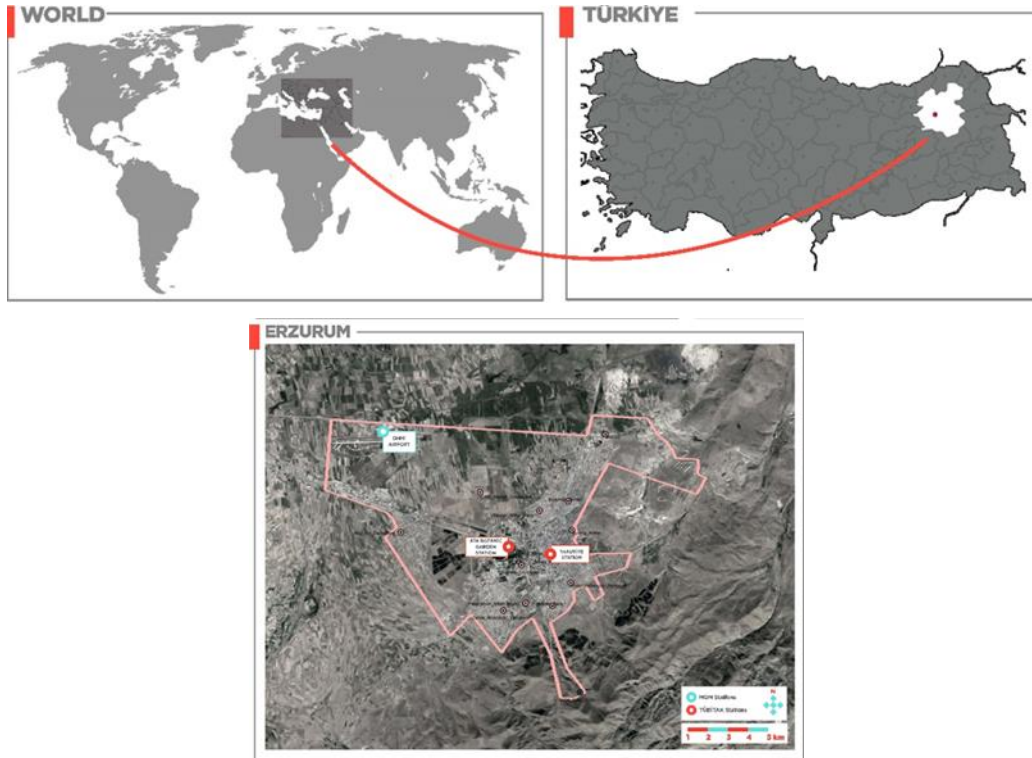

Figure 1. Location Map of the Study Area

In the study, fixed meteorological measurement devices named 'Davis Vantage Pro 2' were used. These devices measure and store temperature, humidity, wind, and precipitation data. While these devices were used in the city center of Erzurum and Ata Botanical Garden, data from the station operated by the State Meteorological Affairs General Directorate at the airport, symbolizing the rural area, was used. The calibration settings of the devices were adjusted.

Thermal comfort refers to the climatic conditions in which an individual adapts to their surroundings with the least amount of energy expenditure, feeling exceptionally healthy and dynamic (Fanger 1970). The Physiological Equivalent Temperature (PET) index is derived from human thermal energy equivalence. Therefore, the PET index is an ideal tool for calculating human thermal comfort in different climate types (Fanger, 1970; ASHRAE, 1997; VDI, 1998; Matzarakis et al., 1999; Höpfe, 1999).

With the recorded data, PET values were obtained using the RayMan Pro 2.1 model for thermal comfort analysis. Figure 2 presents the user interface of the RayMan model.

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

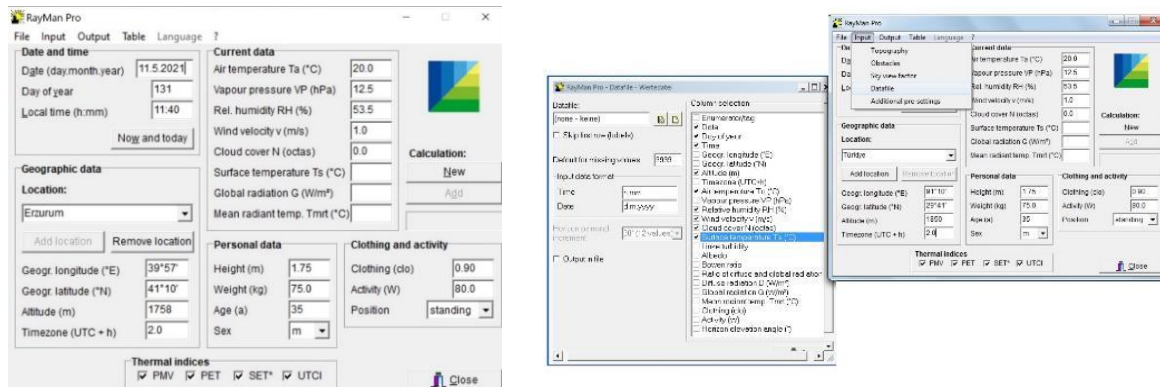

Figure 2. User Interface of the RayMan Pro Model (Matzarakis et al., 1999)

The PET values obtained from the RayMan program are evaluated according to the thermal stress categories of the PET index (Table 1).

Table 1. Thermal Stress Categories of the PET Index (Matzarakis et al., 1999)

PET (°C)	Thermal perception	Grade of physiological stress
< 4	Very cold	Extreme cold stress
4.1 – 8.0	Cold	Strong cold stress
8.1 – 13.0	Cool	Moderate cold stress
13.1 – 18.0	Slightly cool	Slight cold stress
18.1 – 23.0	Comfortable	No thermal stress
23.1 – 29.0	Slightly warm	Slight heat stress
29.1 – 35.0	Warm	Moderate heat stress
35.1 – 41.0	Hot	Strong heat stress
> 41.0	Very hot	Extreme heat stress

3. FINDINGS and DISCUSSION

The measurements conducted within the scope of the study in the year 2022 provided data on temperature, wind, humidity, cloudiness, and PET values.

When examining the micro-climate data, it is observed that the urban area has the highest annual average temperature, with 8.1°C. On an annual average, the urban area is 1.3°C warmer than the rural area and 1.2°C warmer than the green area. In the coldest month, January, the rural area is the coldest with -8.8°C, while the urban area is 2.8°C warmer than the rural area. The green area, on the other hand, has recorded temperatures 1°C higher than the rural area. In the hottest month, August, the urban area has the highest average temperature at 24.0°C, while the lowest averages are recorded in the green area at 21.0°C.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

When examining wind data, it is observed that the lowest average wind speed occurs in January and in the green area, with a value of 0.1 m/s. The highest wind speed, on the other hand, occurs in July and in the rural area, with a speed of 4 m/s.

Looking at relative humidity data, it is noted that the green area has higher humidity values compared to the other areas.

Regarding cloudiness data, a single value was used separately for each station for the relevant hours. Since all stations are located in the city center and its vicinity, the hourly average cloudiness data used by the State Meteorological Affairs General Directorate for Erzurum city was entered as the same value for all stations when calculating PET data. As cloudiness values did not vary among the stations located approximately 5 km apart, different data was not used. The cloudiness value is determined by calculating how much of the sky over the city is covered by clouds, divided into 10 parts, and this value is presented by DMIGM as a single data for Erzurum.

When the PET values obtained using temperature, wind, humidity, and cloudiness data with the RayMan Pro 2.1 program are examined, it is observed that in January, the coldest month, the rural area has the lowest values with -14.7°C . The best values in January were recorded in the urban area with an average of -7.5°C . The green area had an average PET value of -8.1°C . PET values in the green area yielded more favorable results compared to the rural area, with a difference of 6.6°C . According to the PET index categories given in Table 1, all areas are in the "Extreme Cold Stress" category in January.

When examining the hottest month, August, it is seen that the urban area has a PET value of 24.8°C , the green area has a PET value of 23.5°C , and the rural area has a PET value of 18.9°C . According to the thermal stress categories of the PET index given in Table 1, the city center is in the "Mild Heat Stress" ($23.1^{\circ}\text{C} - 29.0^{\circ}\text{C}$) range, while the green area and the rural area are closer to the comfortable range of $18.1^{\circ}\text{C} - 23.0^{\circ}\text{C}$. When annual average PET values are examined, it is seen that the green area provides the best values in Erzurum, a city known for its cold winters. The average PET obtained from the green area is 8.5°C , while this value is 8.3°C in the urban area and 2.4°C in the rural area. In terms of PET values, the green area offers more favorable values compared to the rural area by 6.1°C and compared to the urban area by 0.2°C .

When examining the frequency distributions of PET data in 10-day intervals by months, it is observed that the rural area (State Airports Meteorological Station) is predominantly characterized by very cold, cold, and cool stress levels. On the other hand, in the green area (Ata Botanical Garden) and the urban area (Yakutiye), especially during the summer months, the influence of hot stress is evident.

4. CONCLUSION and RECOMMENDATIONS

As a result of this study, in terms of perceived temperature indicated by PET values, the annual average most favorable values were observed in the green area. The green area provides more favorable values compared to the rural area by 6.1°C and compared to the urban area by 0.2°C . During the winter periods, the urban heat island effect leads to the most favorable results in the urban area, while the green area also provides values close to those of the urban area. PET values in the green area yield more favorable results compared to the rural area, with a difference of 6.6°C . In the summer season, the urban area approaches an average of 25.0°C , which can lead to temperature stress, while the green area comes significantly closer to the comfortable range of $18.1^{\circ}\text{C} - 23.0^{\circ}\text{C}$.

In a study by Yilmaz et al. (2019), conducted using thermal cameras to measure surface temperatures, in winter months, Scots Pine (*Pinus sylvestris* L.) and Birch (*Betula alba* L.) communities and measurements taken from snow-covered parking lots provided the best thermal comfort, with Scots Pine (*Pinus sylvestris* L.) communities being on average 1.8°C warmer. It was found that the surface temperature emitted by the snow-covered parking lots was on average 3.2°C cooler than the others. The study demonstrated that in cities with harsh winters, the establishment of coniferous tree groves is more conducive to creating a more comfortable microclimatic environment with the aim of providing thermal comfort.

Differences in thermal comfort between urban and rural areas are expected, and most studies on this topic have yielded similar results, indicating that the city is always warmer (Asur, 2019; Gülyas et al., 2006; Bulut et al., 2008; İbrahim et al., 2019). Hsieh (2016) emphasized that urban areas are 8.5°C warmer than rural areas in terms of average temperature values. Similarly, Sharmin and Steemers (2015) evaluated climate parameters over a 2-year period for urban and nearby rural areas and noted that the rural area had average temperature values 1.7°C lower.

This study, which evaluates urban, rural, and green areas, has produced parallel results with similar studies. The results of this study have highlighted the importance of green areas for urban microclimate, specifically in Erzurum, a city known for its harsh winters.

ABSTRACT

The Ottoman Empire participated in the First World War as an ally of Germany. This situation caused the Dardanelles to become the primary target of the Allied Powers. Britain, who wanted to get the Ottoman Empire out of the war quickly and cost-effectively, put into practice the plan to cross the Straits with the navy and to take Istanbul. Thus, Britain aimed to keep it in the war by establishing a connection with Russia, and also to seize Istanbul with a fait accompli. However, the attack of the British and French navy on the Dardanelles turned into a great defeat. Thereupon, Britain decided to support the naval attack with land forces. As a result of the preparations, the Gallipoli landings started on April 25, 1915. As a result of the strong resistance of the Turkish soldiers and the critical interventions of Mustafa Kemal Bey, they could not get the desired result without allies, and the war turned into a frontal struggle. This situation caused an anxious wait in the House of Commons, which was waiting for the news of victory in a short time. The deputies, who could not hear from the region due to the censorship imposed by the British Government, started to suspect the British defeat as a result of the news in the German press. For this reason, the censorship policy of the British Government began to be criticized. In this study, the debates about the Dardanelles War and the British Government's censorship policy in the House of Commons after the Gallipoli campaign were analysed.

Keywords: Gallipoli, World War I, Britain.

1. INTRODUCTION

When the Ottoman Empire entered the First World War, the Dardanelles became one of the primary military targets for the Allied Powers. Russia, which needed British and French support, requested its allies to open the Straits (Altıntaş, 1999, 13). Britain and France, who were concerned about Russia's withdrawal from the war, had to take action on this issue (Eyicil, 2009, 319).

Britain aimed to take the Ottoman Empire out of the war quickly and cheaply by seizing the Straits, to establish an anti-German coalition in the Balkans, to keep the Russian Army in the war by providing military support to Russia, and finally to purchase Russian grain to feed its own army (Çetinoğlu, 1994, 725). In addition, Britain took advantage of the request for help and wanted to take advantage of the opportunity to take control of Istanbul, which Russia had wanted to capture for a long time (Sayılır, 2003, 91).

As soon as the Ottoman Empire entered the war, the British navy started attacks on the Dardanelles. Navy-based attack plans against Dardanelles were accepted by the British War Council only in January 1915 (Robbins, 2005, 48-49; Akça, 2006, 3). In this plan, warships were designed to neutralize Turkish cannons and mine search ships to destroy mines in the

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Dardanelles (Edi, 2018, 3). Thus, it was aimed to keep the Ottoman Empire out of war in a short time.

The attacks, which had been continuing since November 1914, reached their peak on March 18, 1915. At the end of the day-long battle, the allied navy had to retreat, accepting that it could not pass the Strait (Eyicil, 2009, 330; Taşkıran, 2001, 21).

Considering the Ottoman Empire as an easy target, Britain implemented a new plan, this time involving land forces. It was envisaged to silence the Turkish artillery with the landings in the Gallipoli Strait and thus to quickly destroy the defenceless mines. After the destruction of the mines, it was decided that the navy would take over Istanbul (Mütercimler, 2021, 78).

The landing operation for Gallipoli started on 25 April 1915. First, landings were made in Arıburnu, Seddülbahir and Kumkale regions (Mango, 2004, 179). The aim of the clashes in Kumkale was to stall the Turkish forces. The aim was for the forces advancing from the Seddülbahir and Arıburnu regions to capture the Kilitbahir plateau and collapse the Turkish defences in Gallipoli (Birinci Dünya Harbi'nde Türk Harbi Çanakkale Cephesi, 2012, 11).

The event that largely determined the fate of the Gallipoli landings took place on the Arıburnu front. After the ANZAC forces landed in the region managed to hold on to the shore, they began to advance, taking advantage of the lack of sufficient soldiers against them. However, Mustafa Kemal Bey's initiative to stop the ANZAC soldiers advancing on the Arıburnu Front changed the fate of the war. Despite the bloody struggle that lasted for months, there was no serious change in this region, and the possibility of the British achieving their goals was eliminated (Babüroğlu, 2021, 195).

Although the Turks had a small number of soldiers in the Seddülbahir region, they managed to resist the numerically superior British throughout the day. The Turkish line had to retreat due to the possibility of being surrounded by British soldiers advancing from bays where there were no soldiers. However, the British could not achieve their goals as the Turkish forces retreating from the Seddülbahir region organized a new defence (Mütercimler, 2016, 295, 303; Volkan, 2011, 139).

Unable to make any progress, the allies launched the Kerevizdere attack on 21-22 June via Seddülbahir in June. Despite the fierce battles that continued throughout June, the Turks managed to defend the front (İlhan, 1994, 679; Aydemir, 2011, 226).

The House of Commons, which expected a quick victory after the landing, could not receive enough information about the war due to the government's censorship policy. Although positive expectations from the war continued in various sessions, news in the foreign press fuelled the discussions. Under these conditions, a session was held in the House of Commons on 30 June 1915 to evaluate the Gallipoli War and the censorship policy of the British Government.

2. MATERIALS and METHODS

The main source of this study is the minutes of the session held in the House of Commons. The minutes of the session subject to the study were obtained from the British Parliament Archives. These minutes were examined within the historical methodology. The speeches in the session were interpreted and, when necessary, information was given about historical events that were necessary to understand the subject. In the conclusion part of the study, evaluations were made about the topic discussed in the session.

3. FINDINGS and DISCUSSIONS

Sir Henry Dalziel was the first to speak at the session. Sir Henry Dalziel recalled the statement made by the Secretary of State for the Home Department and made evaluations on this statement. The Foreign Secretary stated that the army and navy made statements based on the ongoing war situation and did not share some information due to the security of the soldiers. Sir Dalziel said that this information came from the authorities in London and that it was unclear how reliable it would be since it was not received from local authorities. He stated that the statements of the Press Office in London were satisfactory. He underlined that the Press Office shared the information forwarded to it from various institutions, and said that if the information was censored, it was a government decision. He claimed that every member of parliament would understand the government's censorship of some information regarding the course of the war. Sir Dalziel accepted that it was up to the incumbent government to decide what information, good or bad, was or was not in the public interest. However, despite everything, he stated that he preferred the government to make more frequent statements (UK Parliamentary Archives, 1915, 1895-1896). During the war, every country censored information containing military details and news of failures in order to keep the morale of the people high and to ensure the safety of the soldiers at the front. However, although the war has been going on for months and a new front has opened in Dardanelles, inadequate information about the war seems to have disturbed some politicians.

The British Government decided to censor information about the war for military security reasons. Although the House of Commons understood this decision, the fact that very little information was shared about the war started to make MPs nervous. These concerns about censorship were expressed in this speech.

Continuing his remarks, Sir Dalziel asked whether the Foreign Secretary would make a more detailed statement about the military situation in Dardanelles shortly. He stated that his goal was not to discuss the military situation in detail in parliament, and that he doubted whether this would be useful. He stated that military operations were continuing in Gallipoli, but detailed news about this issue appeared in the German press. For this reason, he argued that it would be quite logical for the government to convey information that is in the public interest to the parliament as soon as possible. Sir Dalziel stated that there were many allegations regarding the landing that needed to be discussed. He argued that the attack made before the landing and the claim that the Turks were warned for defence should be discussed. He asked the government to make a more detailed statement as soon as possible. Sir Henry Dalziel stated that if the government trusts the people more, the people will trust the government more and fulfill what is asked of them better (UK Parliamentary Archives, 1915, 1896). The Gallipoli landings aroused great curiosity in Britain. The fact that the Germans shared various information on this issue and the spread of news about the failure of the British undoubtedly increased the demand for information about the war in the House of Commons.

In Britain, the War Council approved the plan to attack the Dardanelles with only the navy at its meeting on January 13, 1915. In this plan, it was decided that the warships would neutralize the Turkish cannons and then destroy the mines left in the Dardanelles. This plan was accepted in its final form on January 28 (Ünalp, 2015, 40). However, it should be noted that the British navy carried out some attacks on the Straits before this plan was approved.

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

The claim in the speech in the House of Commons that the naval attacks on Dardanelles gave the Turks the opportunity to prepare against a land attack is noteworthy. As a matter of fact, the Ottoman Empire has accelerated the fortification of the Straits since the attacks that started in November. As the expectation of a land attack increased after the naval attacks intensified, the Turkish defence in the region was considerably strengthened (Volkan, 2011, 134). This situation is expressed by many soldiers who served in the region, including Mustafa Kemal Atatürk. It is impressive that British politicians realized this when the ground offensive had just begun and they did not have a healthy flow of information about the war.

Sir Arthur Markham reminded that the Secretary of State for the Home Department claimed that the information leaked by the Germans was false and for propaganda purposes and therefore censored. Asking how correct it was to hide the information that the enemy knew and published in the press from the public, Sir Markham stated that the people endured all kinds of sacrifices, including sacrificing their lives in this war. Therefore, he argued that it was pointless for the government to want to pursue a policy of censoring publicly known information. He criticized the current government's censorship policy, arguing that previous governments had not sought the authority to hide unwelcome information from the public, even during war. He stated that it was wrong to hide the information about the Gallipoli War, which Germany and the German people were well aware of, from the British people. Sir Markham argued that it should be disclosed to the parliament how many fronts were established in Gallipoli and what Sir Ian Hamilton reported to London. He also stated that many media organizations sent reporters to the region to follow the war and that the government prevented this information from reaching Britain (UK Parliamentary Archives, 1915, 1897-1898).

From this speech, it is understood that the censorship and the lack of adequate explanations about the war seriously disturbed the politicians. In particular, the German press' various news about the war not only created discomfort among politicians, but also led to the suspicion that there was a defeat in Gallipoli. In addition, the censorship of the news of the reporters sent by the newspapers to the war zone was not received very positively.

Sir Markham stated that while the people endured such sacrifices, Parliament had the right to know how the war was going on. Otherwise, he demanded an explanation of what caused the government not to share the information. Stating that strikes and wage disputes continued in the country, he argued that if the government had provided detailed information about the war, these economic struggles would not have occurred. He stated that members of parliament have learned a little about the war, but people who sent their children to war have not received any information about the war. Sir Markham held the Secretary of State for War, Lord Kitchener, responsible for the censorship that had continued since the beginning of the war. He claimed that he did a good job recruiting soldiers, but that his censorship decision was wrong and harmed the country. Instead, he recommended that existing armies focus on solving their logistics problems. He stated that the censorship originated from the Ministry of War and that it was inappropriate to criticize the press on this issue. Stating that the former government made the decision to censor with the advice of Lord Kitchener and that the current government continues this, Sir Markham argued that this decision should be changed. He requested that military experts come and convince parliament that censorship of existing information is inevitable if the practice is to continue (UK Parliamentary Archives, 1915, 1898-1900).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

During the war, all countries implemented censorship. Apart from this, Sir Markham claims that providing adequate information about the war will have a better impact on the public. Undoubtedly, although censorship concealed the failures, it also led to increased gossip and the public's focus on the troubles brought by the war. In other words, it caused harm as well as benefit. Despite this, governments have continued the practice that has been going on since the past.

Sir Markham stated that even the names of the regiments sent to Gallipoli were not disclosed, but German spies gave these names to the German press. Stating that the people deserve to hear the truth after all their sacrifices, Sir Markham claimed that the government's silence only led to chaos (UK Parliamentary Archives, 1915, 1900). Censorship has been met with criticism, especially in a society accustomed to freedom of the press and the flow of information. This can be noticed from the speeches in the House of Commons.

The Secretary of State for Home Department Sir John Simon stated that army and navy officials decide on the information to be shared before an announcement is made on military matters. He stated that the Press Office worked hard on this issue and worked devotedly to share appropriate information with the public. Explaining that a large team of experts decides what information will be shared, Sir Simon gave an example of a soldier's letter. He explained that the Germans bombed that area 24 hours after one of the soldiers described the view in his letter describing the position he was defending and this letter was published in the press. Although he acknowledged that the application of the rules could occasionally lead to errors, he argued that censorship was important for the safety of fighting soldiers. He claimed that the policy implemented was supported by the entire government and stated that any information that could be useful to the enemy was censored (UK Parliamentary Archives, 1915, 1901-1902).

The main thesis of those who advocated censorship during the war was to ensure the safety of soldiers on the front. However, censorship was also used to hide negative developments from the public. Undoubtedly, since this situation was known to the public, long periods of silence were perceived as defeat. Rather than demanding that all information be openly published, critics of censorship have argued that all information should be shared except that which would endanger the safety of soldiers.

Sir Simon claimed that there were good developments regarding Gallipoli and requested that the information spread through the German Government or the press should not be relied upon. He stated that the German Government was deliberately spreading distorted information and making propaganda in its favour. He claimed that the Germans were trying to influence neutral countries in this way. Sir Simon also stated that if the anti-British news in the German press was reflected in the British press, it was used as propaganda material by the Germans in neutral countries. Sir Simon argued that the claim that no information was given about the Battle of Gallipoli was not true, and stated that a long news story about Sir Ian Hamilton was published on the day of the session. He said that this news was about the developments that took place in the war two or three days ago. He argued that the news coming from the fronts were examined quickly and those deemed appropriate were published without delay (UK Parliamentary Archives, 1915, 1903-1904).

During the war, countries not only implemented censorship, but also carried out propaganda activities aimed at the public opinion of enemy countries. Countries have used censorship to

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

prevent this. Apart from this, it is also clear that governments only want to announce military victories and cover up failures through censorship.

Sir Simon stated that there were positive developments in the Battle of Gallipoli and that the Royal Infantry and the Scots carried out successful attacks. Sir Simon continued his remarks by quoting from Ian Hamilton's report. He explained in the report that the Turks launched attacks against the British trenches, but these attacks were repelled thanks to machine gun and artillery support. He stated that according to the report, more than the expected progress was achieved and Turkish attacks were ineffective. According to the report, he stated that the successful attacks of the 29th Division were the main factor in the progress. Sir Simon stated that this report is satisfactory for both the parliament and the country. Underlining that there are differences between the situation in Gallipoli and Flanders, Sir Simon stated that it was not possible to expand the front in Gallipoli due to geography. He stated that the war could not be managed by the parliament and asked for trust in generals and military officers. (UK Parliamentary Archives, 1915, 1904-1905).

As a result of the defence plan implemented by the Germans in Gallipoli, the British and French managed to hold bridgeheads on the coast. Turkish attacks to drive the invaders into the sea were not really successful. However, the Turks made a successful defence and prevented the advance of the Allied forces. The progress mentioned by Ian Hamilton was quite short-lived.

Sir Simon also spoke about the censorship of news sent by newspaper reporters from the Gallipoli Front. He also argued that information thought to endanger the military situation was censored in line with the opinion of the military authorities. He stated that the news sent by reporters from Gallipoli will continue to be examined and only those deemed appropriate will be shared with the public. He stated that similar actions were taken in every region of the war, and that no special application was taken for the Gallipoli Front. He argued that the information collected by reporters in the war zone was analysed by military authorities in the region and censorship was decided there. He claimed that no new action was taken in London over the censored reports coming from the region. However, he stated that if an important overlooked issue is noticed, a second censorship may be applied. Stating that the appropriate reports sent by Ian Hamilton will continue to be disclosed to the parliament, Sir Simon announced that the same information will also be shared with the press (UK Parliamentary Archives, 1915, 1905-1907).

It is understood from Sir Simon's speech that the British censored the news sent from the war zone both in that region and in London. The fact that the censorship on the Gallipoli Front, rather than the censorship on the Western Front, was discussed in the session shows that the Gallipoli landings were followed with enthusiasm in the House of Commons. It is also noticeable that providing limited information regarding the landing increases the suspicion of defeat.

4. CONCLUSION

When the British planned the naval attack on Dardanelles, they were excited for an easy victory against the Turks. The British public did not believe that the Ottoman Empire, which had been defeated by small states during the Balkan Wars, would be able to resist the British navy.

After the British navy accepted defeat on March 18, 1915, action was taken to support the naval attack with land forces. It was planned to capture the Gallipoli peninsula and neutralize the

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Turkish cannons with the landings to be made through Seddülbahir and Arıburnu. The Allied attack started on April 25, 1915. Although they made progress on the Seddülbahir front, they were eventually stopped by Turkish forces, which marked the end of the British's advances on the southern front. The fate of the Battle of Gallipoli was largely determined when the advance of the ANZAC forces on the northern front was stopped by Mustafa Kemal Bey.

Wanting to cover up the failures, the British Government imposed intense censorship on the news about the Gallipoli War. Suspicions peaked when the House of Commons, expecting an easy victory against the Turks, could not receive information about the war. For this reason, shortly after the Gallipoli landings, discussions began in the House of Commons regarding the censorship applied in the war. This shows that the House of Commons wanted to follow the Gallipoli landings closely. The British Government continued to censor news about Gallipoli, using military security as an excuse. Even the articles of the reporters sent by the newspapers to the region were censored both in the war zone and in London. In addition, the government shared minor progress in the region with the parliament. However, the small amount of sharing for the front has led to doubts about success. The news published in the German press also increased the unrest of the British MPs.

Considering the session on censorship, it is noticeable that the positive expectations of the House of Commons for the Gallipoli War began to disappear as early as June. The British Government's censorship decision further increased the negative feelings of MPs. The news in the German press about the defeat of the British further fuelled the concerns. The most striking point is that, in addition to criticizing the government's censorship policy, doubts about the defeat in the war were expressed in the session and accurate inferences were made about the possible reasons for the defeat.

ABSTRACT

Human has been building for centuries. They create a house by carving a rock, a hut from a tree branch, a mud brick that brings water and soil together and putting what is in nature on nature again. These actions were initially carried out to protect, hide and improve living conditions as the basic instinct of the need for shelter. However, in the historical process, it has left its place to a system based on overconsumption by producing more than it needs over time, just like in the war of human with nature. With the modernist era which tends to consume rather than produce, the concept of peoples housing tendencies, which is assimilated as a home physically and psychologically, has turned into a standardized and ordinary housing concept. Especially with the modernist era which tends to consume rather than produce, the housing concept tendencies has also changed. Analyzing the change in human habitation in the evolutionary process; first of all, it requires understanding people and thinking about the construction of human-made spaces. Because; It is important to read the semantic connotations of the concept of home through the spatial analysis of philosophy, which takes its priority from the way of thinking of people, and to reveal its change. The main purpose of this study, which is prepared on the basis of this problem, is; The aim is to reveal the changing priorities and features of modern man's act of building to dwell, and thus to draw an evolutionary schema of the degeneration of the concept of home. In this context, firstly, Gaston Bachelard and Martin Heidegger's philosophical perspectives on the concept of housing are examined and the changing meaning of the concept of housing is revealed through the philosophy of space.

Keywords: Martin Heidegger, Gaston Bachelard, Dwelling, Resettlement, Build.

1. INTRODUCTION

Home is our living space where we hide on earth. This need for hiding, which initially arises from physical environmental conditions, points to an order based on protecting our self and soul in the modern age. In this context, the house has become a shelter similar to the medieval cellars of the modern world.

"Home", which is the abode of our memories and moments, is a place where we place our memory (Bachelard, 2013). It shapes and imprisons our memories by witnessing our moments with our dreams that it determines in concrete and abstract terms and the place it has acquired in our minds. The space bounded by this concept cloud constitutes the parts/rooms of our home.

However, with the modern age, housing, which has become uniform and shaped by passing through the mass production line, has lost its spatial meaning and has become an object of consumption. The uniqueness of individuality has become increasingly similar to each other in housing areas, each of which has become a copy of each other. This situation harms not only

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

individual diversity but also the subjectivity of streets and the cultural identity of cities. In summary, the concept of home is the degenerated shelter of the modern age.

Figure 1. Evolutionary Scheme of the Nest

2. MATERIALS and METHODS

The main purpose of this study is to search for the lost meaning of the concept of home by revealing the changing priorities and characteristics of modern man's act of building for shelter. In this context, Gaston Bachelard and Martin Heidegger's perspectives on the concept of home are analyzed. The human-space-time analysis of the concept of home based on the literature review is analyzed through modern examples that seek a new meaning for home.

Gaston Bachelard, who defines space in a poetic language beyond concrete descriptions or abstract analogies, explains in his work *The Poetics of Space* how language, the main element of this poetic approach, freezes space in time and solidifies it into an image (Bachelard, 2013). In this context, according to him, the overlap of human-space-time is most clearly possible through the depiction of the house on memory and memories because home is the place where memories and dreams are most intensely engraved in our minds. In other words, the house as a place witnesses all our moments and creates memories. Bachelard, who says that even in a new house a whole past lives on, defines "home" - and therefore space - as a "place" that produces memories. According to him, space is the memory of individuals, and this memory is formed by the furniture, the smell and texture of the furniture, and the human experience of these senses. By being furnished with dreams and memories, memory spaces cease to be a physical "object" and into an essence (Leach, 1997).

Heidegger believes that dwelling, which has been lost in the modern world, constitutes the essence of human existence (Sharr, 2013). He explains that the simplification, decontextualisation, standardization and transparency of the home as a result of modernisation processes have turned people into "existential strangers" in the world. Stating that the housing crisis, especially as one of the global effects of World War II, has become a housing problem in the world age, Heidegger emphasizes that, with a similar understanding, the meaninglessness of cultures, lives and artifacts arises from the same source (Sanrı Doğan, 2022). Unlike Bachelard, Heidegger looks at home not as a reflection of happy memories, but as a reflection

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

of inner troubles, and in this context he criticizes the modern world in particular (Heidegger, 1971).

3. FINDINGS and DISCUSSION

The transformation of the home into an object of consumption is a current topic of discussion in interdisciplinary art and design studies. In this context, many manifesto-like works have been put forward. In this section of the study, these works are analyzed.

- **Splitting, Gordon Matta Clark, 1970**

In the 1970s, when the deconstructive design language had not yet become widespread worldwide, American architect and artist Gordon Matta Clark used a deconstructive style in which he cut, separated and exploded some floors or structural elements of abandoned buildings and in this context reproduced the space in question (Barria, 2011). Just like Derrida's understanding of deconstruction, the concept of "detournement", in which Clark's work is intertwined, endeavors to critically target the relationship of the capitalist order with the social masses and to create an incentive to realize the questioning of social space. Clark thinks that for a conceptual interrogation in the production of spaces and the subject of spaces, language, as a condition of the control mechanism of social ideologies, must also be displaced, and in this respect, he exhibits a similar attitude with Derrida (Yılmaz, 2022).

Figure 2. Splitting, Gordon Matta Clark, 1970 (Can, 2017)

In this context, Gordon Matta-Clark has reproduced the modern "house" from an inverted perspective. Like Heidegger, he rejected the decontextualized, commodity-like structure of housing and based his designs on the movement and temporality Heidegger advocated. Clark, who is interested in social problems in his designs, focuses on the main problem area of "home" with an unusual perspective and reproduces "home" with striking fiction (Sanrı Doğan, 2022).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

- **Rachel Whiteread's House, 1993**

The artist Rachel Whiteread, who chose a house in a residential area planned to be demolished by the British government for the purpose of publicization, created a sculpture to be exhibited in its current location by making a mold of the house (Cohen, 2018). This work is an unspoken manifesto of the rebellion of people who refused to leave their homes for many years but eventually had to leave their homes. The interior walls of the house, which had already been ordered to be demolished, were covered with concrete and the bricks on the exterior were removed one by one from this concrete skeleton. In Whiteread's work, rooms that are never entered, doors that do not open, windows that do not look anywhere symbolize the freezing and solidification of "home" as a meaning in a temporal context. With this sculpture, space becomes a mental image beyond representing a physical object as a house.

Figure 3. Rachel Whiteread's House Street Facade, 1993 (Cohen, 2018)

- **Basic House, Martin Azua, 1999**

Martin Azua has created the Basic House prototype with the idea of a pocket-sized private dwelling as a counterpoint to the problems of ownership and the difficulties of home ownership. As a "foldable, inflatable and reversible" volume, the house offers a new alternative to the modern concept of property. The artist wanted to create an immaterial house in response to the fact that housing today is the end product of a series of consumption habits of our living spaces. This structure, which adapts to natural conditions, can swell with sunlight and air, and protects from cold when reversed, is based on the basic requirements of shelter. In this context, from a Heideggerian perspective, it reveals a method of having everything without having nothing (Azua, 2012).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

**Figure 4.** Basic House Working Principle Diagram (Azua, 2000)**Figure 5.** Basic House Phenotype, 1999 (Rosenfield, 2012)**4. CONCLUSION**

The house, as a shelter and a place of living, turns into a home only when it is identified and subjectivised as a whole with memories. The human being produces that space with the desire to be at home and return home. In this state of being, home and subject are one. However, the new housing order of the modern age has made this subjectivity ordinary and easy from an objective point of view. The house has now become a companion space that pursues material concerns.

As a result, housing, which is constantly produced as a copy of each other in today's modern metropolitan cities, is becoming an object of consumption that does not allow for any experience and hosts rootless memories. The decontextualization of spaces creates societies without memory. In this context, it can be said that housing, which provides the opportunity for socialization, encounter, meeting and acquaintance, has become a new design problem.

MICRO LANDSCAPE DESIGN IN URBAN AREAS

Assoc. Dr. Elif Sağlık (ORCID: 0000-0002-5230-3869)

Çanakkale Onsekiz Mart University, Faculty of Architecture and Design, Department of
Landscape Architecture, Çanakkale-Türkiye

Email: elifsaglik@comu.edu.tr

ABSTRACT

Cities are laboratories where many disciplines carry out studies and they are important places where multidisciplinary studies are carried out. In this context, the study has assumed a unique value by showing a micro-scale approach to landscape design in urban areas. Micro landscape design is a process that pays attention to details, scale and balance and aims to make the best use of the available space. Micro landscape design, which increases the aesthetics and functionality of cities, contributes to the quality of urban life and is realized in small- scale and carefully considered areas. The design focuses on maximizing the environment by using small areas effectively. It saves time and energy, often requiring less maintenance than larger landscapes. This design, which is advantageous in terms of flexibility, offers solutions supported by various equipment. Micro landscape design is an important type of landscape design due to its advantages such as aesthetics, low maintenance, economical, environmentally friendly and suitable for personal preferences. Taking these features into account, the scope of this study is to explore sample urban areas for the applicability of micro landscape designs and to develop design proposals for these areas. Thus, it is aimed to provide a perspective for the inclusion of neglected areas in the city with the design discipline and to provide a perspective for the transition to large-scale landscape designs by addressing landscape design at the smallest scale.

Keywords: Landscape Design, Micro Design, Urban, Urban Design.

1. INTRODUCTION

Urban areas function as a kind of laboratory where experts from various fields come together and interact with different disciplines. This implies that cities can play a significant role in addressing complex and diverse issues from social, cultural, economic, and environmental perspectives. Cities facilitate collaboration among individuals from different areas of expertise to understand and solve various problems.

There is no consensus among theorists, scientists, and researchers when it comes to defining a city. This lack of consensus arises from the variability in criteria used to define a city. A city is a densely populated settlement that spans a relatively large space and exhibits continuity in space, comprising individuals who do not necessarily share social similarities (Keleş, 2016).

Altaban (2018) defined the urban phenomenon with different approaches such as economic location, formal-intuitive design, perceptual, social and historical, urban morphology. According to the economic site selection approach, he emphasises the importance of economic factors in urban planning by examining factors such as land use, land values and accessibility in the definition of the city. The formal-intuitive design approach is based on the assumption that there is a definite relationship between the physical environment and activities and that the designer can play an effective role in shaping society. The perceptual approach is concerned

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

with the spatial and physical components of the city and emphasises the importance of how the city is perceived. It enables the creation of quality spaces by providing a balance between the elements of the city and using them in diversity. The social and historical perspective treats the city and its parts as outcomes of societal production processes, closely linking urban history to societal and economic structures. Urban morphology approach considers the city from both physical and social aspects, highlighting a continuous and inseparable interaction between physical form and social processes, forming the basis for urban morphology (Altaban, 2018).

Based on the definitions provided for the urban phenomenon, cities are seen as complex and dynamic spaces that consist of various components. These components include physical infrastructure elements such as streets, buildings, parks, and transportation systems. The harmonious coexistence of these components is vital for maintaining the functionality and aesthetic integrity of cities. This is where urban design comes into play.

Urban design is not limited to planning the physical environment; it also shapes the social and cultural structure of the city. This discipline is critical not only for the aesthetics of cities but also for improving the quality of life, safety, and well-being of individuals. Consequently, urban design is recognized as a critical tool for understanding the complexity of cities, developing sustainable, human-centered solutions, coordinating and integrating the physical and social structure of the city.

Madanipour (1996) defines urban design as the management of change within built and natural environments. From this perspective, urban design is closely related to macro-scale urban planning. However, when urban design is considered as the design of small urban areas on a micro-scale, it aligns with the aesthetic and spatial interests of architecture and the arts (cited in Aydın Türk, 2016).

Urban design is an approach used to shape the physical and social structure of cities at different scales:

- On a macro scale, it focuses on urban morphology and the perceivability of the city, developing strategies for detailed description of public space obstacles.
- On a meso scale, it includes revitalization, improvement, and revitalization of the urban fabric based on various data such as social, cultural, physical, and more. It also aims to regulate the physical environment of large-scale housing designs in new development areas.
- On a micro scale, this approach includes design principles that enable the inclusion of architectural products and the immediate environment in the social and physical environment.

Therefore, urban design theory and practices are used to support the sustainable and human-centered development of cities by considering different dimensions (Aydın Türk, 2016).

Urban quality of life depends not only on economic prosperity but also on various other factors. Strategies for improving urban quality of life include increasing green spaces, creating accessible and sustainable transportation systems, improving infrastructure, and optimizing public services. These strategies offer solutions that enhance urban quality of life, enabling people to lead happier, healthier, and more satisfying lives. Improving urban quality of life

TeMALab

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

encompasses the effort to transform cities into places where people can live better, healthier, and more sustainable lives (Tükroğlu & Koramaz, 2016).

Urban planning and design are legal documents that guide decision-making regarding the preservation, renewal, and development of areas within and around the city. Urban design provides a general framework for the direction of change in public spaces (Özer, 2017). As Karaman (2008) puts it, urban design includes the process of applying criteria in social, economic, ecological, and morphological areas that determine the dynamics of urban development to physical space.

In this context, this study emphasizes the potential of landscape design from the perspective of urban design to make aesthetic and environmental improvements in overlooked areas of urban texture. Within the scope of this study, the potential is evaluated through micro-landscape design to beautify and increase the sustainability of urban environments.

Micro Landscape Design and Its Characteristics

In urban areas, landscape design refers to the process of arranging and enhancing open spaces, parks, streets, squares, and other green or open areas in cities. This design encompasses factors such as environmental arrangement, vegetation arrangement, aesthetic planning, and usability.

In urban areas, landscape design encompasses subtopics such as aesthetics and visual appeal, environmental sustainability, user experience, reduction of social isolation, health and well-being, climate change and water management, preservation of cultural and historical values, traffic regulation, and economic development.

Throughout history, landscape and environmental design began with the existence of humanity. People started shaping their living spaces according to their needs by settling in nature. Landscape design, initially in the form of small-scale garden arrangements, evolved into larger-scale designs to prevent environmental degradation with the increase in human settlements (Yaşar & Düzgüneş, 2013).

In urban areas, landscape design is an essential tool to enhance the livability of cities, improve environmental sustainability, and promote higher quality of life for people. Landscape design combines natural and artificial elements to plan and arrange outdoor spaces both functionally and aesthetically. This often involves a large-scale process, addressing general issues such as how large areas will be organized, where plants will be placed, and how road networks will be designed. However, in addition to this large-scale approach, micro landscape design holds significant importance.

Micro landscape design emphasizes the smallest details of landscaping. Considered complementary to comprehensive planning, micro landscape design aims to enrich people's interactions with natural and artificial spaces. In this regard, the basic principles of what micro landscape design is and how it is a process can be summarized as follows:

- **Attention to Details:** Micro landscape design focuses on small-scale details, including elements such as plants, decorative features, and other particulars of landscape design.
- **Scale and Balance:** It ensures that the design is aesthetically balanced and harmonious. Achieving balance between large and small elements is necessary to obtain visually pleasing results.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

- **Efficient Use of Existing Space:** Micro landscape design aims to make the best use of the available space. This involves optimizing the use of space and minimizing unnecessary gaps, ultimately aiming to provide maximum functionality and aesthetics in a small area.

In other words, micro landscape design aims to optimize the smallest features of a landscape and ensure that these details work together in harmony. The general characteristics of the micro landscape design approach can be outlined as follows:

Evaluation of Overlooked Areas: Often focusing on areas that are neglected or underutilized in urban spaces and examining how these areas can be improved through landscape design. It can contribute to making cities more efficient and aesthetically appealing.

Enriching the City with Design Discipline: Emphasizing how these overlooked areas can be incorporated into the city using design discipline. It can contribute to the enhancement of cities both aesthetically and functionally.

Creating a Perspective for Large-Scale Design: Expressing how micro landscape design can provide a perspective for large-scale landscape designs, starting from small-scale details. It aims to consider how small-scale design decisions can contribute to the overall urban design.

There are various areas within urban centers where micro landscape designs can be implemented. These areas vary depending on their locations and functions in the urban fabric. Examples of areas suitable for micro landscape design include, but are not limited to, narrow streets, unused spaces, courtyards or rooftop terraces of apartment buildings, areas integrated with urban furniture such as sidewalk benches, trash bins, or bicycle parking spaces, and the vicinity of public transportation points such as bus stops, train stations, or tram stops (Figure 1). Improvements made in these areas through the micro landscape design approach play a crucial role in coping with urban congestion, preserving the natural environment, and helping people avoid the stress of city life.

Figure 1. Examples of Urban Micro Landscape Design (URL, 1)

Mikro Landscape Design, like macro and meso scales, cannot be precisely defined in terms of physical space; rather, it can be described by various other terms in the context of urban areas, including:

- Urban botanical areas
- Urban micro-green spaces
- Details of urban landscaping
- Urban gardens
- Urban green pockets
- Small-scale urban landscaping
- Small landscape compositions
- Mini park (pocket park)
- Miniature urban nature arrangement
- Street landscaping
- Urban miniature landscaping

The choice of terminology for micro landscape design can vary depending on the context in which it is used and the specific characteristics of the design.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Regarding the conceptual diversity in micro landscape design, Gina (2016) presented examples at macro, meso, and micro scales. Urban development projects at different scales have emphasized the potential to enhance urban quality of life, strengthen connections, and improve environmental and economic health through open space and infrastructure improvements. An example at the micro scale is the area known as "Lawn on D," which was constructed as a vibrant and temporary open space. This space includes a spatial layout and programming designed to express and test the goals of the new region. Created with limited investment, this micro-scale open space has become a powerful example and pioneer in achieving more with fewer resources, inspiring other projects. Additionally, it is considered an experimental space that supports uses beyond traditional park programming, serving as a gateway to increase public participation and satisfaction (Figure 2).

Figure 2. The urban context of the sites the Massachusetts Convention Center Authority (MCCA) oversee in South Boston

In this study, Hamdy & Plaku (2021) provides another example of conceptual diversity in micro landscape design. The focus of this study is on the concept of 'mini parks,' and its characteristics are explained. Mini parks are defined as small landscape areas that fill vacant lots or unused spaces in areas where property interest has been overlooked. These areas have been described in the literature using different terms such as mini-parks, vest-pocket parks, or neighborhood parks. In 1963, Robert Zion proposed the use of mini parks as small-scale environmental restoration elements in densely populated urban areas in an exhibition titled 'New Parks for New York.' In this context, Paley Park, which served as a model for mini parks worldwide, was constructed in 1967 (Johnson & Frankel, as cited in Hamdy & Plaku, 2021).

Another example of conceptual difference for micro landscape design is the study by Hamdy & Plaku (2021). In this study, the focus was on the concept of mini parks and the characteristics of this concept were explained. Mini-parks are defined as small landscape areas that fill vacant land areas or unused areas where real estate interest is overlooked. Such areas have been described as mini-parks, vest-pocket parks or neighbourhood parks under different names in the literature. In 1963, Robert Zion proposed the use of mini-parks as small-scale environmental restoration elements in dense urban areas in an exhibition titled "New Parks for New York". In this context, Paley Park, which serves as a model for mini parks around the world, was built in 1967 (Johnson, & Frankel, 1991 cited in Hamdy, & Plaku, 2021).

Micro landscape design is often recognised as an important component in the creation of mini parks or pocket parks, but micro landscape design and mini parks refer to different concepts. Micro landscape design is concerned with the planning and implementation of plant arrangements, landscape elements and details in small areas.

On the other hand, mini parks or pocket parks are small public spaces that aim to create green spaces in limited areas, usually in cities. Such parks are organised using the principles of micro landscape design, but micro landscape design is not limited to mini parks; it is also a concept used for general landscape design. The elements that bring these concepts together are listed as follows.

- Small Scale Design: It is related to small scale design and arrangements. Both usually require working in limited areas.
- Plant Arrangements: Micro landscape design and pocket parks are related to plant arrangements and landscape elements. The selection of plants, their arrangement and maintenance are important in both cases.
- Aesthetic Value: Both concepts require aesthetic attention. Both micro landscape design and pocket parks aim to enhance environmental beauty and aesthetic value.
- Usability: It aims to create areas that people can use and enjoy. Seating areas, walkways and similar features are important in terms of usability.

Advantages and Features of Micro Landscape Design

Micro landscape design consists of a process that includes a wider range of design elements, including a seating unit, ground covering, boundary element, plant arrangements as a component. In this process, there are various advantages such as flexibility, support with equipment, aesthetics, low maintenance, economic, environmentally friendly and suitability to personal preferences.

Flexibility Advantage: A flexible approach to micro landscape design can offer solutions that suit different areas and needs. This makes it easier to customise the design and adapt to existing conditions.

Supporting with Accessories: Micro landscape design is made more functional by supporting it with various accessories and elements, enriching the design aesthetically and functionally.

Other Advantages: Aesthetics, low maintenance, economic, environmentally friendly and suitability to personal preferences come to the fore.

Aesthetics: Micro landscape design provides aesthetically attractive and visually satisfying results even in small areas.

Low Maintenance: The design is characterized by low maintenance requirements, reducing maintenance costs.

Cost-Effective: It offers economic advantages, even on a smaller scale.

Environmental-Friendly: It can include environmentally friendly solutions in line with sustainability principles.

Compatibility with Personal Preferences: The design can be customized according to personal preferences and cater to users' desires.

Micro Landscape Design Process

Based on the information conveyed regarding the characteristics, advantages, and definitions of micro landscape design, there are several stages for implementing micro landscape design in urban areas, from site identification to post-implementation. These stages include site analysis, microclimate and soil analysis, area usage decisions, integration with urban fabric, accessibility analysis, sustainability evaluation, ease of maintenance, and ensuring user engagement.

Site Analysis: The initial step in micro landscape design involves a detailed analysis of the urban area. This analysis meticulously examines the size of the area, existing landscape features, environmental conditions, and intended use. Factors such as the size, shape, existing vegetation, and environmental factors like the direction of sunlight and wind are considered during this stage.

Microclimate and Soil Analysis: Micro landscape design requires a detailed evaluation of the climatic and soil conditions of the area. In this context, microclimate characteristics of the area such as sunlight intake, wind direction, temperature changes should be determined and soil analysis should be carried out. Climate and seasonal conditions are critical for plant selection and therefore, it is necessary to select plant species suitable for the climate of the region. At the same time, the soil structure of the area should be analysed and factors such as soil drainage, nutrient content and pH level should be evaluated in order for plants and landscape elements to grow properly.

Land Use decisions: Micro landscape design involves defining the various use zones of the site and developing unique micro landscape designs for each zone. For example, recreation zones, picnic areas, playgrounds, etc. should be considered separately for different zones. According to the intended use of the area, the type of activities and user needs are important.

Compatibility with Urban Texture: Designing by taking into account the surroundings of the area and nearby structures and should be compatible with the urban texture. Factors such as architectural style, environmental elements, other structures in the area, roads and walkways play a role in shaping the design.

Accessibility: Increasing the use of the area and ensuring that everyone can benefit from it is important in terms of easy accessibility and comfortable use.

Sustainability: Micro landscape design should consider the principles of sustainability. Sustainability principles such as water conservation, use of local materials and protection of natural resources should be at the centre of the design.

Ease of Maintenance: In order to ensure that the design is easy to maintain, attention should be paid to the selection of plants and the arrangement of elements. Measures should be taken to facilitate maintenance.

Participatory Design Approach: In urban area design, the opinions of local residents and users are of great importance. Adopting a participatory approach in the micro landscape design process and considering the views of the local community can help align the design with community needs and preferences.

2. CONCLUSION

In an era of rapid urbanization, the preservation of natural areas and the creation of green spaces have become increasingly crucial. Making cities greener and more sustainable is achievable through proper design and planning. Micro landscape design provides an area where urban dwellers can effectively contribute and engage. In this context, micro landscape design plays a key role in supporting the health and sustainability of our cities.

In a world where green spaces are diminishing, micro landscapes shine as a way to create small-scale green areas and promote biodiversity. Micro landscape design not only encourages the preservation of green areas in cities and the creation of new ones but also improves air quality, maintains temperature balance, and contributes to water management. Moreover, it enhances the psychological and physical well-being of individuals while bringing communities together.

Through this study, the critical role and potential of micro landscape design in cities have been explored. Urban planners, designers, and local authorities should consider micro landscape design as a priority that needs to be integrated and encouraged. Using this valuable tool is essential to build sustainable cities and better prepare for the future.

ABSTRACT

*The experiment was carried out to investigate the effects of gamma-ray irradiation on the color and chlorophyll contents of St. Augustinegrass (*Stenotaphrum secundatum* (Walt.) Kuntze). Two distinct clonal genotypes of St. Augustinegrass, exhibiting coarse ('G') and extremely coarse ('M') textures, were subjected to irradiation at varying dosages of 0, 50, 100, 150, and 300 Gy and 0, 20, 40, 80, and 120 Gy, respectively, using a ⁶⁰Co source. The study included a total of 15 mutant lines exhibiting a dwarf growth pattern. In order to determine the potential differences in turfgrass color between mutant lines and non-irradiated control plants, color measurements were performed on the leaves of five randomly selected shoots using a Minolta Chroma Meter. The chlorophyll content of leaves was assessed using a randomly selected 15 shoots with a Chlorophyll Meter. The amount of color differences seen in mutants was relatively lesser in comparison to those documented for other species of turfgrass or horticultural crops. No significant differences in chlorophyll content were found among mutant lines and control plants of the M genotype. Nevertheless, the chlorophyll content of the mutant lines, specifically G20-2, G40-6, and G120-1, exhibited a reduction of around 20% when compared to the control group within the G genotype. The utilization of gamma-ray radiation, known for its role in promoting diverse pigmentation and coloration in horticultural crops, did not yield the anticipated beneficial outcomes in St. Augustinegrass.*

Keywords: Mutation, Turfgrass, Plant Breeding, Radiation

1. INTRODUCTION

St. Augustinegrass, scientifically known as *Stenotaphrum secundatum* (Walt.) Kuntze, is a perennial turfgrass species that is commonly utilized in green spaces within subtropical and tropical climate zones. The precise origins of St. Augustinegrass are uncertain; nonetheless, it is recognized as a native species of turfgrass in North America. Over time, it has proliferated significantly along the coastlines of Central and South America, Australia, and the Pacific region (Chen, 1992). St. Augustinegrass is commonly utilized in residential and public gardens across the United States due to its notable capacity for shade tolerance, comparatively lower maintenance requirements in comparison to other warm-season turfgrass species, rapid soil coverage facilitated by its stolons, and resilience against salinity (Reynolds et al., 2009).

Bermudagrass is a species that exhibits strong adaptability to the Mediterranean and Aegean coastal regions of Türkiye, making it a highly favored choice. This preference stems from its

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

rapid establishment capabilities and its capacity to withstand heavy traffic. Nevertheless, due to its limited ability to tolerate shade and its need for a minimum of 6-8 hours of direct sunlight to achieve optimal development and growth (Sever Mutlu et al., 2011), greenkeepers are compelled to seek alternate turfgrass species suitable for shaded regions. In this regard, St. Augustinegrass emerges as a significant alternative turfgrass species suitable for places with partial shade and shade conditions, characterized by low levels of foot activity. Although St. Augustinegrass has significant promise for shaded places, it remains relatively unfamiliar in Türkiye. Two significant factors contributing to the restricted adoption of it in Türkiye are its incapacity to establish through seed and its coarse leaf texture. Seed production poses challenges due to genetic factors. Due to this circumstance, it is unfeasible to generate novel St. Augustinegrass cultivars with suitable turf attributes by the conventional hybridization approach. Hence, the utilization of mutation breeding appears to be a significant technique in the cultivation of novel St. Augustinegrass cultivars (Çakır, 2016).

Mutations are characterized as heritable alterations in the DNA sequence due to modifications in the physical and chemical composition of the genetic material (van Harten, 1998). Both physical and chemical mutagens offer effective methods for the development of novel varieties. Mutation breeding enables the generation of genetic diversity in a more expedited manner compared to traditional breeding techniques, facilitating the identification and selection of plants possessing desirable traits from this pool of variation (Taş, 1999). Mutations can arise through natural processes or be induced through intentional means. In recent years, researchers have employed nuclear techniques as mutagens and utilized radiation to induce genetic diversity in seeds and different plant components. This approach enables the identification of acceptable plant selections from among the pool of mutant candidates (Demir & Turgut, 1999). Mutation breeding studies involve the use of ionizing radiation, such as UV rays, X and gamma rays, alpha and beta particles, protons, and neutrons, to induce mutations. The utilization of gamma radiation is extensively favored in the context of physical mutagenesis applications due to its ease of use, capacity to effectively reach target cells owing to its high permeability, and absence of any toxic or detrimental consequences (Schum, 2003).

Mutation breeding has been used successfully in turfgrasses (Tan et al., 2009). It is recommended to use the gamma irradiation approach in the development of new varieties of vegetatively grown turfgrass species (Powell et al., 1974). Many researchers have applied irradiation to turfgrasses and received positive results. For example, the 'Coastcross II' Bermudagrass variety, which produces a denser and higher-quality turfgrass cover, was obtained from the 'Coastcross I' variety to which 70 Gy dose gamma rays were applied (Li, 2007). Among the Bermudagrass species, 'Tif Eagle' (Hanna & Elsner, 1999), 'Tift 94' (Hanna et al., 1997), and 'Tifway II' (Burton, 1985), which are widely used on golf courses, were obtained by gamma irradiation. Dwarfism has been identified as the prevailing mutant trait arising through mutation breeding, as documented by Powell et al. (1974). Nevertheless, researchers have successfully cultivated cultivars that exhibit enhanced seed yield, improved grass quality, a more intense green hue, improved resistance to heat, drought, and fungal infections, as well as an earlier onset of spring regrowth.

The objective of this study is to assess the impact of gamma radiation on the chlorophyll content and color of two distinct clonal genotypes of St. Augustine.

2. MATERIALS and METHODS

This research was carried out between February 2014 and November 2015 at Akdeniz University Faculty of Agriculture Research and Application Greenhouses. Gamma-ray applications were carried out at Akdeniz University, Faculty of Science, Department of Physics Laboratory. Two different clonal genotypes of St. Augustinegrass, showing coarse ('G') and very coarse ('M') texture, were irradiated at doses of 0, 50, 100, 150, and 300 Gy and 0, 20, 40, 80, and 120 Gy provided by the ^{60}Co source, respectively. Rooting of stolons in viols, selection of promising genotypes, growing of these genotypes, and morphological measurements on the plants were carried out in the greenhouse environment. Details regarding plant materials and method of development of mutant lines used in our previous study (Çakır et al., 2017). A total of 15 mutant lines with dwarf growth habit and finer leaf texture used in this study. Selected mutant lines and their non-irradiated control plants were propagated clonally. The stolons collected from the selected plants were cut into single-node cuttings and planted in plastic pots, each pot containing 15 stolons. The study was conducted in a randomized block trial design with three replications. Stolons were watered regularly to prevent water stress. Starting from the 2nd week after planting, the plants were periodically fertilized once a week with 18-18-18 (N-P-K) compound fertilizer at a rate of 2.5 grams of N per m².

Measurements were made to determine the variation in turfgrass color and chlorophyll contents 12 weeks after planting. Color values were determined with the Minolta Chroma Meter CR 400, Osaka, Japan. The color measurements were conducted on the leaves of five shoots that were randomly chosen within each pot. The Chlorophyll values were collected with a handheld chlorophyll meter (Field Scout CM 1000 Chlorophyll Meter; Spectrum Technologies, Inc., Plainfield, IL), measuring the reflected red and far-red light ratios to calculate the relative chlorophyll content at 80 cm height above the plot surface. The output is a unitless index of chlorophyll content on a scale of 0 to 999. The chlorophyll value of each pot was averaged from 15 readings per pot.

Treatment differences were tested using ANOVA procedures with PROC GLM (SAS Institute, 1999). Means were separated using Tukey's studentized range (HSD) test ($P < 0.05$) procedure.

3. FINDINGS and DISCUSSION

Color, a significant component of the aesthetic quality of turf and the genetic manifestation of turfgrasses, is a crucial selection criterion used by turfgrass breeders in the development of new cultivars. The response of turfgrass pigmentation to treatments may be used as an indicator of treatment efficacy or turfgrass injury potential (Berndt, 2023). The results for the color of turfgrass are presented in Table 1. Although not statistically significant, a*, b*, and C values changed in both directions for both genotypes. Only genotype G showed a statistically significant change in L* value compared to controls. G80-1 and G20-1 had the lowest and greatest L* values respectively. Powell et al. (1974) exposed dormant rhizomes of Bermudagrass 'Tifdwarf' to 68 Gy, 90 Gy, and 113 Gy of gamma radiation and obtained 71 mutant lines. According to them, the most distinguishing morphological characteristics of these mutant lines were color-tone variations and dwarfism. In addition, they indicated that hue values of color mutations were shifted in both directions, and comparable to our study, some of the mutants had light green and light yellow hues. Powell & Toler (1980) administered 45 Gy, 58 Gy, and 70 Gy of gamma radiation to the dormant stolons of the St. Augustine 'Floritam' plant. They obtained 14 lines of mutants. The resulting Mutant-1 line exhibited pink-colored

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

foliage. It has been reported that since the 'Floratam' genotype is a hybrid between a line with pink leaves and a line with non-pink leaves, this change may be a spontaneous variation.

Table 1. The effects of gamma ray applications on color of St. Augustinegrass

Genotypes	Lines	L*	a*	b*	C
Genotype 'M'	M-Control	40.82 ^{A1}	-14.50 ^A	19.89 ^A	24.42 ^A

	G120-1	38.68 ^{abcd}	-14.70 ^a	21.60 ^a	26.14 ^a

¹Lettering was done by testing each genotype separately. Capital letters indicate the comparison of the averages given for the 'M' genotype, and lowercase letters indicate the comparison of the data for the 'G' genotype.

²According to the LSD test, different means at the 5% significance level are shown with the same letters.

Table 2 presents the results for the chlorophyll content of the mutant lines. There was no statistically significant difference between the chlorophyll content of the 'M' genotype's control plants and mutant lines (Table 2). In the 'G' genotype, the chlorophyll content of G20-2, G40-6, and G120-1 mutant lines decreased by 17–20% relative to the control plants, whereas the chlorophyll content of the other mutant lines did not differ statistically from the control. This study's findings are inconsistent with those of Sever Mutlu et al. (2015). Sever Mutlu et al. (2015) irradiated the tetraploid 'B-165' genotype of bermudagrass at doses of 70, 90, and 110 Gy and obtained four mutant lines. They reported that the mutant lines contained 19% more

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

chlorophyll than the control plant. Fehr (1987) reported that the sensitivity of various plant species and genotypes within the same species to any mutagen may vary. Busey (1980) investigated the effects of gamma-ray dosages on seven distinct St. Augustinegrass genotypes and varieties. The author obtained a total of 22 mutant lines that exhibited chlorophyll deficiency. The findings of our investigation correspond with those of Busey (1980).

Table 2. The effects of gamma ray applications on chlorophyll content of St. Augustinegrass

Genotypes	Lines	Chlorophyll content	Difference according to control	Difference according to control (%)
Genotype 'M'	M-Kontrol	264.37 ^{A1}	-	-
	M50-1	250.20 ^A	-14.17	-5
	M100-1	240.50 ^A	-23.87	-9

4. CONCLUSION

A darker green color and a higher chlorophyll content are desirable characteristics of turfgrass. The level of green color variation within mutants was lower than that reported for other turfgrass species and horticultural commodities. Gamma-ray applications, which help to develop flowers of different colors/tones in horticultural crops, did not positively affect the chlorophyll contents of St. Augustinegrass genotypes evaluated within the scope of this study. Additional research using a broader range of mutant lines is necessary to ascertain whether alternative genotypes/cultivars of St. Augustinegrass provide mutant variants exhibiting more favorable coloration and elevated chlorophyll levels in response to gamma radiation.

Acknowledgments and Information Note

The present study originates from the master's thesis titled "Improvement of Turfgrass Quality by Gamma Ray Irradiation in *Stenotaphrum Secundatum* (Walt.) Kuntze," which was conducted by the first author under the guidance of the second author at the Department of Landscape Architecture, Institute of Natural and Applied Sciences, Akdeniz University. This project was funded by the Akdeniz University Scientific Research Projects Coordination Unit under the project code FYL-2015-543.

ABSTRACT

The population and urbanization rate, which continues to increase rapidly in the world and in Türkiye, also brings about destructions in green areas and agricultural areas. The expansion of cities towards fertile lands leads to reductions in agricultural areas, thus causing problems in food supply, meeting basic needs, breaking the human-nature bond and negatively affecting the quality of life of the citizens. This situation forces the world to produce innovative understanding and policies that integrate agriculture into cities. Edible landscaping is an innovative and sustainable landscape design approach that increases human-nature interaction, provides convenience in safe food supply, and has advantages in many economic, social and environmental issues. With the acceleration of urbanization, settlements with high agricultural potential may face losing this potential over time. Thus, both increasing the agricultural potential and providing easy access to food increase the popularity of edible landscapes day by day. These arrangements made with plants that are edible and do not contain any toxic substances are not much different from the traditional landscape made with ornamental plants in terms of maintenance and design. However, providing access to organic, fresh and healthy food and providing educational and instructive social areas for unity, togetherness, sharing and raising awareness make edible arrangements more attractive and advantageous. In this study, the definition and purpose of edible landscape arrangements, their advantages, disadvantages, design and maintenance have been revealed and examples of edible landscape applications in the world and in Türkiye have been examined.

Keywords: Urban Agriculture, Edible Landscape, Sustainability, Urban Food Supply.

1. INTRODUCTION

Nowadays, with the development of industry and technology, the migration of people from rural to urban areas increases the density in cities and also brings with it many problems. According to United Nations Population Fund (UNFPA) data, the world population, which was approximately 7.9 billion in 2021, is expected to exceed 8 billion by 2025 and 9.5 billion by 2050 (URL-1). It is also known that as of 2021, 56% of the world's population and 93% of Turkey's population live in cities. It is estimated that this rate will increase to 68% in the world and 98% in Turkey by 2050 (URL-11). With these population densities exceeding the capacities of cities, the need for accommodation, food and beverage, commercial, social and public areas and transportation axes between these areas increases day by day. In order to meet all these

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

needs, existing residential areas have gradually expanded into green areas and agricultural areas, which causes serious damage in these areas. The need for safe food increases with the increasing population and decreasing agricultural areas; this situation threatens soil and water resources. Migrations that start from rural to urban areas with the idea of increasing people's welfare level, over time, bring about unplanned urbanization, thus lands used for purposes other than intended, destroyed forests and agricultural areas, degraded landscapes and habitat areas. These negativities have initially ignored due to the attractive opportunities offered by development; later, they have started to become a problem that made it difficult to meet basic needs. (Demirci,2018; Meral & Doğan,2020).

Human beings are creatures that try to establish a bond with nature and keep this bond strong as a result of their physical and spiritual needs. Today, the rapid increase in urbanization and the destruction of parks, gardens and green areas cause people to stay away from nature (Demiroğlu,2023). Therefore, there is a need to create alternative solution areas to increase the presence of green areas in the city, which have many sociocultural, economic and environmental benefits, and to make arrangements that integrate the activities carried out in rural areas into cities at a more minimal scale and increase human-nature interaction. These arrangements appear in different applications, including roof and terrace gardens, urban agricultural areas and agroparks, eco farms, hobby gardens, permaculture areas, and edible landscaping. (Demirci,2018; Meral & Doğan,2020; Kapan & Öztoprak,2020).

Edible landscaping arrangements, which have a significant contribution to the establishment of urban agricultural areas and constitute the subject of this study, are decorative landscaping arrangements that increase people's awareness of learning and protecting nature, contribute to the supply of safe food, and can be a socializing and active area. While edible landscaping enables aesthetic and decorative images to be achieved by choosing suitable plants, they also offer the opportunity to benefit from the medicinal and aromatic fruits or leaves of the plants used. The purpose of edible landscaping is to produce and consume food, help people socialize, and also provide decorative spaces. Day by day, efforts to grow plants that can be consumed as food are gaining momentum in parks, roadsides, roofs, terraces and vertical gardens, public spaces and campus areas, in short, wherever communities spend time during the day (Meral & Doğan,2020).

In this study, first of all, information about the definition and purpose of edible landscaping, as well as their advantages, disadvantages, design and maintenance will be given. Then, edible landscaping examples in the world and in Türkiye were discussed and suggestions on the subject were developed.

2. WHAT IS EDIBLE LANDSCAPE?

Edible plants are productive plants with fruits or leaves that can be safely consumed by humans without toxic effects. Edible landscaping arrangements are arrangements that take into account the aesthetic and decorative properties of these food-producing plants. These plants, which are used for aesthetic and consumption purposes, generally do not aim to make commercial profit. While the aim is to contribute to the food demand of the increasing population in the most economical way, it is also to encourage local product consumption, to create social areas where people can have a good time, to increase people's awareness of nature and production by including children, especially children, in the production stages, and to obtain aesthetic, decorative and sustainable landscapes. Edible landscaping is a progressive and innovative food

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

systems approach that encourages and supports all people to consume local food, whether in private or community spaces and workplaces (Thompson and Sokolowski, 2016).

Edible landscaping uses food-producing plants. These plants, which are used for both their food and decorative properties, can be trees, shrubs, shrubs or herbaceous plants (Meral & Doğan,2020; Demiroğlu,2023). Fruit and nut trees, vegetables, medicinal plants with medicinal-aromatic properties, and ornamental plants with edible flowers and leaves are brought together in these arrangements to obtain aesthetically pleasing images. The location and design of these gardens or the types of plants to be used may vary depending on the purpose of use (medicinal-aromatic garden, fruit garden, etc.) or user density (home garden, city park, etc.). This situation is entirely at the discretion of the designer. Edible landscapes offer an alternative to ornate traditional landscapes established for purely aesthetic purposes. They stand out as an efficient landscaping alternative by integrating food-producing plants into ornamental plants and traditional designs (Kourik, 2004). Simply put, edible landscapes replace decorative plants with plants that both decorate the environment and produce food. They can create attractive and aesthetic images with their colorful fruits or flowers and scented or textured leaves in edible landscapes as well as in traditional landscapes designed with exotic ornamental plants. In recent years, the fact that the maintenance, fertilization and irrigation costs of edible plants are almost the same compared to ornamental plants has increased the popularity of edible landscapes and they have begun to be preferred more frequently in new regulations. In fact, we can say that these investments are more advantageous than traditional landscapes made with ornamental plants, as they provide returns on investments with the supply of fruits and vegetables. There are countless edible plants that can be grown in our country. These plants can be easily included in landscape designs in a locally appropriate way, instead of exotic plants used in traditional landscaping. Thus, it also contributes to obtaining sustainable landscape areas (Fetouh, 2018; Falla et al., 2020)

In fact, the concept of edible landscape is not a new concept. Since ancient times, people have taken care to use edible plants in gardens for different purposes. If we examine the gardens of different civilizations from history to the present, the gardens of Ancient Iran appear as the first gardens where edible plants were used together with ornamental plants. It is also possible to find edible ornamental plants in ancient Egyptian temples (Fetouh,2018). Edible fruit trees and medicinal plants were frequently found in medieval monastery gardens (Beck and Quigley, 2001). Aromatic plants were also used as spices in ancient Greek and Roman civilizations (Melillo, 1994; Cichewicz et al., 2004; Nowicka et al., 2019). The Hanging Gardens of Babylon are also one of the first examples in history of both edible landscaping, roof terrace gardens and vertical gardens (Meral et al., 2018). The purpose of using edible plants in the gardens of the Renaissance period was to meet the need for food and to create a place where one can have a pleasant time with various aromatic fruits. In addition, these fruits were harvested and sold to the public, and the expenses of the palace were covered with the income obtained. It is known that vegetables were frequently used in Renaissance gardens (Wilhelmi, 2013; Çelik, 2017).

The concept of edible landscape was introduced to the literature in the 1980s by Robert Kourik, a landscape designer and environmentalist. It started with the idea that aesthetic designs could also be achieved with these plants in gardens where crops were grown. In 1982, Rosalin Creasy clearly expressed the concept of edible landscape for the first time with her article titled 'The Complete Book of Edible' and introduced it to the landscape world. (URL-2). Edible

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

landscaping arrangements are becoming a part of the public day by day and cause changes in the plant species used in landscape design (Creasy, 2010).

Figure 1. Edible Landscaping Examples (URL-3)

3. ADVANTAGES AND DISADVANTAGES OF EDIBLE LANDSCAPE

3.1. Advantages of Edible Landscaping

Edible landscapes are landscaping arrangements that involve aesthetic concerns while growing crops in order to facilitate access to safe food and provide social spaces for people, despite the negativities brought about by rapid population growth and urbanization in recent years. These regulations, which are just beginning to become widespread today, provide people with many advantages in economic, environmental and socio-cultural terms. These advantages can be summarized as follows.

3.1.1. Economic advantages

One of the negative consequences of the population growth brought about by rapid industrialization and urbanization is undoubtedly the growth of cities towards green areas and agricultural areas and the damage to agricultural lands. Decreasing agricultural areas compared to the increasing population makes it more difficult for people to access safe food day by day. Edible landscapes are a solution to these problems and enable people to easily obtain the food they need in daily life. People who access edible plants in their home gardens, city parks and workplaces can save the energy they spend on transportation. In addition, the energy spent on delivering food to people is also saved. Thus, people's ability to access vegetables and fruits whenever they want will also reduce current food costs. Edible landscapes established on small scales show the same efficiency as traditional landscapes established with ornamental plants. Edible landscapes planned on large scales provide more suitable environments for activities such as pollination and fertilization among plants, thus increasing the quality and quantity of products. Thus, the food yield obtained per unit area will also increase. (Meral & Doğan, 2020). Studies show that almost 25% of a city's food needs can be met if the resources used for garden maintenance costs in public gardens, city parks and home gardens are used for edible landscaping. With edible landscaping, extra costs and energy spent for food production, consumption and transportation in cities are reduced and more food is obtained. (Halweil, 2002; Beck & Quinley, 2003; Fetouh, 2018).

3.1.2. Environmental advantages

In addition to facilitating access to fresh and safe food, edible landscaping enables the healthy continuity of water, soil and wildlife and increases biodiversity (Fetouh, 2018). Using edible ornamental plants in landscaping in urban areas saves energy in the maintenance, harvesting, transportation, packaging and waste management of these plants. (Bohn and Viljoen, 2005).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

This situation directly affects both the environment and the economy. Thus, by reducing the use of fossil fuels, it also contributes to the reduction of greenhouse gas emissions that cause climate changes. In addition, it is possible to mention the many benefits of edible arrangements for the environment, such as contributing to the reduction of the urban heat island effect, retaining rainwater flowing into surface flow, and providing functionality and revitalization to empty and idle areas in the city. (Robinson ve ark., 2017).

The use of chemical pesticides and hormones is also increasing in order to meet the increasing food demand and increase the yield obtained per unit area in agriculture. Landscaping arrangements containing edible plants prevent water and soil from being exposed to these chemical-containing pesticides, while facilitating access to natural and healthy food by reducing hormone use. Green spaces with sweet and aromatic plants serve as habitats for insects and birds. Attracting some bird species that feed on insects to the area with edible arrangements will reduce pesticide use. With these regulations, people will be directly involved in the growing periods of plants and will turn to food obtained in more organic and reliable ways. (Henderson, 1987).

3.1.3. Social advantages

In addition to providing people with areas where they can socialize, edible landscaping creates areas that increase human-nature interaction and strengthen the bond within society. Human beings are creatures that tend to be in touch with nature due to their physical and spiritual needs. Well-planned landscaping arrangements allow people, who today have to live disconnected from nature among high-rise buildings, to increase their interaction with nature. Edible landscaping increases and facilitates this interaction, as they are landscapes that offer activities such as growing and harvesting plants. Edible landscaping in a neighborhood park increases the opportunity for collaboration and socialization among neighbors and families during plant care and harvesting. (Holmer and Drescher, 2009). In addition, these interactions of people with nature will increase awareness of ecology and environmental protection. it helps both to provide a solution to the problem of malnutrition and to obtain economic profit from the harvested crops, especially in places with low-income communities. Regulations consisting of edible plants have the potential to meet the raw material needs of industries such as beekeeping, textile, cosmetics and spices. Since it helps to obtain and consume organic products, it also has a significant impact on protecting social health. (Lovell and Taylor, 2013).

3.2. Disadvantages of Edible Landscaping

While renewable landscaping arrangements bring advantageous solutions to many problems, they can also have disadvantages when the right application and maintenance are not provided in the right place. There are many factors that trigger environmental pollution in urban areas where human activities are intense.

These can be listed as exhaust gases resulting from heavy traffic and vehicle use, dirty, toxic greenhouse gases released from industrial sites and causing climate changes, and heavy metals that do not decompose in nature or require a very long time to decompose. These elements directly threaten the plants used in the edible landscape and indirectly threaten human health. In the master's thesis prepared by Batır (2019), the heavy metal concentrations in the organs used as food of fire thistle, linden, apple, rose, walnut, oleaster, cherry and sour cherry species grown in the city center of Eskişehir were compared with the heavy metal concentrations in

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

other organs. Within the scope of the study, the concentrations of Sodium (Na), Aluminum (Al), Barium (Ba), Cobalt (Co), Cadmium (Cd) and Lead (Pb) elements in the leaves, branches and fruit organs of these plants are determined and their negative effects on human health are mentioned. As a result of the study, significant changes were observed in the fruits exposed to the elements subject to the study. One of the most important results of the study is that the highest Co, Cd and Pb concentrations were obtained in fruits. These heavy metals are among the most important and dangerous heavy metals for human health.

According to these results, it is thought that edible landscaping applications may cause serious health problems. Authorities should always raise public awareness about not consuming fruits found in areas exposed to these pollutions. In addition, edible landscaping applications should not be used in flood areas or areas where the natural quality must be preserved. (Angotti, 2015). Conflicts between foragers are likely to arise during the harvest period in edible landscape areas. This is one of the disadvantages of regulations. This situation can be solved by regulating and keeping under control the limited collection. (McLain et al., 2014). Failure to choose locally appropriate plant species and varieties in edible arrangements can turn into a disadvantageous situation as it will require excessive care and damage biodiversity. In addition, not cleaning ripe fruits that cannot be collected during the harvest period in these areas and rotten fruits that have broken off from their branches will attract pests. If pest control is not achieved, these areas may turn into areas with bad smells and appearance that are unfit for human use. (Meral & Doğan, 2020; Demiroğlu, 2023). However, despite all these disadvantages, when edible landscape areas are planned and designed correctly, they are ecological and sustainable arrangements whose advantages outweigh their disadvantages.

4. DESIGN CRITERIA FOR EDIBLE LANDSCAPE AREAS

Edible landscaping is the practical integration of food plants into a decorative environment. Edible plants can be combined with another edible plant or ornamental plants in well-planned designs. The biggest challenge in edible landscapes is to create designs that allow urban residents to provide food by imitating natural life without harming the natural environment. (Fetouth, 2018). These designs are realized by using vegetables and bushes with edible fruits instead of plants without edible parts. Many people like the idea of including functional plants (edibles and wild plants) in their ornamental plants. But in reality, it is not always easy to achieve an acceptable aesthetic without careful design and attention to plant selection and each plant's growth habit and needs. (Sousa, 2016). Edible landscapes should offer decorative images as well as useful areas where the user can easily access food. Additionally, it is not necessary to use entirely edible plants in edible landscapes. The rate of use of edible plants should be adjusted depending on the intended use of the designed area and the user density.

Because producing more food than necessary may cause excessive maintenance costs and also lead to waste. Instead, delicious, practical and visually pleasing spaces should be created with the reasonable use of fruits, plants and vegetables. (Creasy, 2010).

Essentially, edible landscaping is designed using the same design criteria as traditional landscaping. However, edible plants should be used together, paying attention to their growth habits and needs. For example, an ornamental plant that is resistant to arid climates and requires low maintenance and a fruit tree that requires regular watering, pruning or fertilization should not be used in the same arrangement. This situation harms the healthy development of both plants and is valid for all edible or ornamental plants to be used in the design. Parks, streets

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

with low traffic density, roadsides, and home gardens are suitable areas for edible landscaping. Depending on the wishes of the users living here, arrangements can be made using one or more types of edible plants. The conditions that will make these arrangements successful can be listed as follows: using plants that are reliable and require less maintenance, using plants that look visually attractive and grow faster, using plants that people cannot easily access in the markets, choosing the right plant combinations, establishing irrigation systems suitable for the plant, and preferring smaller areas. (Hensen, 2016). In addition to all these, it is also of great importance to avoid regulations that would endanger the continuity of wildlife, to leave the necessary spaces to facilitate healthy development and maintenance for plants, and to pay attention to plant diversity to ensure the continuity of edible food throughout the year. Considering the characteristics of the selected plants such as form, texture, size and color, using them in harmony in the designs and taking into account the color, smell, aroma and taste of the fruits make edible landscape areas much more attractive. Edible herbaceous plants generally have a short lifespan. Therefore, arrangements made together with evergreen perennial plants provide edible landscapes that grow continuously throughout the year without losing their visual effect (Demirci, 2018; Demiroğlu, 2023).

5. MAINTENANCE IN EDIBLE LANDSCAPING

Arrangements where edible plants and ornamental plants are placed together may bring some opportunities and challenges. In practice, the design criteria used in arrangements with edible or ornamental plants are the same, but there may be a few details that edible plants are sensitive to. Both ornamental and edible plants need care. But xeric ornamental plants, which require less care, are also frequently used in landscapes today. However, in order to obtain yield from edible plants, it requires extra care in matters such as irrigation, fertilization, pruning and pest management. Edible landscapes require maintenance at regular intervals. Unfortunately, if these maintenance processes are not carried out regularly and continuously in a system, these advantages can turn into disadvantages. Therefore, individuals, institutions or organizations responsible for edible landscape areas should place these maintenance processes in a regular system and ensure their controls carefully. These maintenance costs can be minimized by placing the right plant combinations in the right places. For this, plant materials suitable for the local area should be selected, and the wishes and needs of the plants should be taken into account. Not applying the same amount of chemical pesticides or fertilizers to each plant is an important issue in edible landscapes. Before applying the chemicals to be used, their suitability for edible plants should be checked. Edible plants generally require more watering than ornamental plants. Therefore, the irrigation needs of the plants used in the arrangements are an important factor in the designs. Using the hydrozonation method, plants with the same water needs are used together. Thus, the plant is exposed to neither less nor more water than it needs. Edible plants may need pruning to increase crop productivity. Persons or organizations that undertake the maintenance and control of the area should carefully apply the pruning process at appropriate periods throughout the year in order to obtain a productive area for the product and ensure its continuity. (Meral & Doğan, 2020).

6. EDIBLE LANDSCAPE DESIGN EXAMPLES FROM THE WORLD AND TÜRKİYE

In this section, some edible landscape design examples in the United States of America (USA), Cuba, Dubai Emirate, England, Hong Kong and Türkiye are mentioned.

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

Edible Landscaping in the USA: The first examples of edible landscaping in the USA began to be implemented during the economic crisis between 1875 and 1917. During these periods, people tried to be least affected by the crisis by obtaining significant amounts of product through their voluntary participation in the maintenance of urban agricultural areas. Although almost 80% of the US population lives in cities, the fact that 40 million hectares of urban area is covered with grass indicates that edible landscaping practices are needed here and these grass areas are considered an opportunity for edible landscaping. (Beck, 2001). Protecting 40 million acres of land with grass and turning these areas into edible landscapes for the more than 54 million Americans who maintain these lawns every weekend is important for the development of urban-scale agriculture. While edible landscaping in these areas is made in the form of traditional vegetable gardens in some designs, in others it is made with ornamental plants by integrating annual vegetables into the general landscape (Demirci, 2018). (Figure 2)

Figure 2. Edible Landscape Design Examples in the USA (Demirci, 2018)

Dubai Urban Agriculture Park: The world's longest urban agriculture park in Dubai is designed to transform the city's longest road into an eco-valley. In the project that re-planned the Sheikh Zayed Road, which is the busiest and longest road in the city, the 25 km long road, which divides the city into two and covers an area of 350 hectares, was underground and transformed into first-class urban agricultural land. This project enabled the establishment of public spaces in order to direct social capital development, provide economic value and support sustainable growth. The park consists of air-conditioned indoor spaces, 80% efficient urban agriculture farms as well as open-air palm plantations. It was planned with the aim of reducing the environmental footprint by reducing the cost and energy consumption of transportation and storage of food grown in the city center. Apart from being an urban agricultural area, it has been designed as an environmentally, economically and socially sustainable park by choosing a vegetative design suitable for the existing vegetation and encouraging the use of local materials. (URL-4). (Figure 3)

Figure 3. Dubai Urban Agriculture Park (URL-4)

Cuba/Havana Urban Agricultural Areas: After the 1959 revolution in Cuba, agricultural development policies were initiated to prevent intensive mechanized and tillage agriculture. As a result of these policies, Cuba, whose population was 10 million in the 1980s, was able to

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

produce enough food for approximately 40 million people. However, in 1990, problems in trade and the slowdown in food production caused an economic crisis, and as a result, agriculture began to be practiced in urban areas. In the early 1990s, with the pressure brought by the historical and economic situation, the state began to see urban areas as an important source of food production. Over time, efforts have been made to meet the food needs of the urban population to a large extent. In this process, families living in the city began to cultivate not only in their own gardens, but also in the gardens of their workplaces and in urban open and idle areas. In the 2000s and later, the Cuban Government applied edible regulation methods at three different land scales in order to find local solutions to the food supply problem in the city of Havana. The first of these is the arrangement made by planting edible plants in potted gardens created by filling containers with fertile soil in asphalt or stone-paved infertile areas. The second way was to arrange idle areas in the city with edible plants. The third way was for people to cultivate their own home gardens with edible plants. Intensive gardens, which involve the use of intensive gardening methods to grow the maximum amount of produce on small-scale land, are another edible landscaping method applied in urban areas. In this method, various edible plants are planted in plant beds placed in a tightly arranged arrangement on large areas of land that are not separated by walls or fences. (Keskin & Yildirim,2019). While all these practices are carried out by the state or different institutions/organizations, local governments also allocate land for the use of private individuals. (Koont, 2004).(Figure 4)

Figure 4. Cuban Edible Landscapes and Urban Farming Areas (URL-5)

Edible Landscaping in England: Britain, which has the largest agricultural production potential in the European Union (EU), left the EU with a decision taken in 2016, which led to some uncertainties in the agricultural sector. The UK, which receives more than half of its total agricultural income from aid within the scope of the EU's Common Agricultural Policy (CAP), increased the incentives for local agricultural products in this period in order to avoid difficulties as a result of the termination of these aid. For this purpose, with a program first initiated in the city of Leeds, gardens with fruit trees such as apples and almonds were established in urban areas under the name of 'Public orchards'. Fruit trees were planted in green areas with voluntary public participation, thus aiming to increase beekeeping activities. In addition, while existing agricultural production facilities were protected, farms were established in urban areas and public access to fresh food was facilitated. These urban farms also provide great benefits in education and public awareness. (URL-6). (Figure 5)

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Figure 5. UK Urban Farming Areas And Edible Landscape Designs (URL-7)

Hong Kong Urban Farm Design: Nowadays, the idea of farming in urban areas is widely seen in Hong Kong, especially in order to alleviate the urban heat island effect. Urban farm areas, established by prioritizing locality and sustainability, are planned as common areas that offer different activities where city residents can share their experiences and relax. The areas that allow for increased human-nature interaction also appear as arrangements where edible plants are used predominantly to encourage the continuity of agricultural activities. (URL-8). (Figure 6)

Figure 6. Hong Kong Edible Landscape Arrangements (URL-8 & URL-9)

Edible Landscaping Examples from Turkey (Istanbul Yedikule, Roma and Kuzguncuk Orchards): The increasing rate of urbanization in Turkey after the 1950s caused agricultural lands to be occupied and agricultural lands to be pushed out of the city. While horizontal urbanization started towards existing agricultural areas, agricultural areas were opened to settlement and some of the forests were tried to be converted into agricultural areas (Kapan & Öztoprak, 2020). Over time, Istanbul has been affected by the negative effects of rapid urbanization and has turned into a city where green areas are destroyed, ignoring ecological sustainability. Edible landscape areas have begun to have an important place in order to improve the decreasing quality of life in the city and to increase and strengthen people's connection with nature, which has been interrupted. The first place that comes to mind in our country regarding agricultural and edible landscape areas in urban areas is undoubtedly Istanbul Yedikule Orchards. These gardens, which date back to the Byzantine and Ottoman times, were established to meet the fresh food needs of the Topkapı Palace and the public. According to the information obtained from old written sources, it is known that there were 54 orchards in the region from Yenikapı to Topkapı, and according to a guarantor book prepared in 1735, there were 344 orchards and 1381 workers working in these orchards. (Shopov & Han, 2013). As a result of infrastructure and superstructure works during the Republic period, some of these gardens were damaged and could not be protected. Istanbul Orchards, which still exist today, continue as a strip parallel to the city walls between Bayrampaşa valley, Langa, Yedikule and Topkapı, all the way to Davutpaşa. (Kuban, 1996). Although these orchards still exist, they are planted by people called gardeners and contribute to the food supply of the district where they

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

are located. Today, the gardens, which are maintained voluntarily by neighborhood residents and local governments, also instill people's awareness of collective living and offer activity areas where they can socialize. Garden areas, where the calmness of working with the soil and the interaction with nature increase, are frequented by many people and are used as areas for residents to have access to fresh and organic food and to have a pleasant time. The food produced here is shared with the neighborhood residents as well as the immigrant cuisine. Thus, it provides an environment for increasing cooperation and solidarity and sharing experiences. Although different agricultural techniques are used in each garden, there are also differences in the products each garden specializes in. (Karpuz,2015). (Figure 7)

Figure 7. Istanbul Kuzguncuk and Roma Orchards Edible Landscape Arrangements
(Karpuz,2015)

In recent years in Türkiye, arrangements where edible plants are grown in urban areas have begun to be seen frequently in hobby gardens established with the support of local governments. Hobby gardens are gardens that offer individual areas where edible plants are planted and harvested for the purpose of increasing interaction with nature and having a pleasant time. These gardens, organized using edible fruits, vegetables and medicinal-aromatic plants, can be shown as examples of edible landscaping areas in cities. The rate of urbanization is quite high in Türkiye, and hobby gardens have become widespread, supported by institutions such as municipalities and universities, as a solution to the negative effects of rapid urbanization. (Figure 8)

Figure 8. Hobby Gardens in Istanbul, Kayseri and Konya (URL-10)

7. CONCLUSION and RECOMMENDATIONS

Edible landscaping are arrangements that offer practical solutions to the negativities brought by urbanization. These regulations are made to improve the quality of urban life, to facilitate access to safe and healthy food, to create areas that allow people to socialize by drawing attention to the awareness of living as a society, and to help ensure the sustainability of natural resources.

With edible landscaping arrangements, people can witness the growth and harvest periods of plants as agriculture is carried out in urban areas, and they can also consume these organic foods, in which they are involved in the cultivation stages, more safely. Although edible

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

landscapes have many advantages in economic, social and environmental terms, they can also have disadvantages in some cases.

Productive landscapes that allow people to be involved in these production stages that produce edible healthy foods can turn into useless and disadvantageous areas unless proper care and control are provided. Therefore, maintenance and checks should be carried out by a person, institution or organization in a regular and meticulous system. Edible landscapes, where correct plant selection and correct irrigation, fertilization and pest management are provided, are always more efficient and advantageous compared to traditional landscapes. To increase these advantages, edible landscaping should be areas designed with a sustainable approach.

ABSTRACT

Sustainability is a key concept used in many fields today. The concept, which takes its place in the urban planning literature, offers solutions against the negative effects of urbanization and rapid industrialization on societies and the environment. In order to ensure the development of cities in line with the principles of sustainability, it is extremely important to have indicators that will help the development goals to be monitored and evaluated. Today, there are 23 urban sustainability indicators put forward by different countries and organizations in the international arena. The most of these are "United Nations Guide to Urban Indicators" and "European Foundation Urban Sustainability Indicator". In this study, the criteria in these two basic indicators are discussed and the contributions of urban open-green areas to the urban sustainability targets of the relevant criteria are examined on the basis of "ecological", "economic" and "socio-cultural" headings. The findings revealed that urban open-green spaces are one of the main actor of sustainability.

Keywords: Sustainability, Urban Sustainability, Urban Sustainability Indicators, Urban Open-Green Spaces.

1. INTRODUCTION

The main challenge facing today's cities is to reduce the heavy dependence on ecosystem services that lead to the depletion of natural resources and biodiversity. It is also to manage climate change mitigation and adaptation efforts by prioritizing public health and quality of life (EC, 2015). At this point, integrating the concept of sustainability into urban planning and management has become very important, especially in recent years (EC, 2015).

The concept of sustainability emerged in the early 1970s as a reaction to the fact that modern development practices of the period began to cause social and environmental crises around the world. It was used for the first time in 1972 by Donella Meadows and her colleagues in the book "The Limits to Growth". By modeling global population, resource consumption, and pollution trends, they predicted humanity's collapse in the mid-21st century. They emphasized that a sustainable future is possible by changing the growth trend and ensuring ecological and economic balance conditions. (Meadows et al., 1972). The concept, together with the concept of development, was first defined in the 1987 report of the World Commission on Environment and Development (Our common future report - Brundtland Report) as "meeting the needs of the present without compromising the ability of future generations to meet their own needs." (BM,

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

1987). Although there are many different definitions of the concept of sustainable development today, varying according to different themes, the necessity of a holistic approach to ecological, economic and social-cultural issues is emphasized in all definitions. (Yıldırım & Akkaya, 2020). In the following periods, the concept became a subject of research in many fields and began to be used. One of these areas is urban planning.

The concept of urban sustainability has emerged as a discourse that can positively affect the quality of life of individuals as a result of the uncontrolled and uncontrolled growth of urbanization, which greatly affects the livability and quality of life in urban areas (Çolakoğlu, 2019). According to Kennedy et al. (2007), *“a sustainable city can only be one for which the inflow of material and energy resources, and the disposal of wastes, do not exceed the capacity of the city’s surrounding environment. In other words, for achieving environmental sustainability urban consumption must match or be below what the natural environment — such as forests, soil and oceans — can provide, and the resulting pollutants must not overwhelm the environment’s ability to provide resources to humans and other members of the ecosystem”*. (EC; 2015). This concept, which requires solutions at a global level, aims to protect and develop environmental resources, as well as to build social solidarity in a society, increase economic empowerment and opportunities, and develop environmental awareness. (Çolakoğlu, 2019).

Urban sustainability has economic, social, cultural and political dimensions. Because the city covers all these dimensions. Activities carried out in cities affect many important elements and require the development of different strategies. It is extremely important to determine the strategies in question according to the scope of planning and the problems and possibilities of the area to be planned, and to look at all these problems and opportunities in an integrated manner, from the planning scale to the design components (EC, 2015; Tuğaç, 2018; Demiroğlu, 2021). At this point, sustainability indicators are very important to create sustainable urban spaces. These indicators measure and evaluate policies, infrastructure, socio-economic factors, resource use, emissions and other processes that contribute to and benefit from the city's metabolism, well-being and quality of life. Urban sustainability indicators are tools that allow urban planners, city managers and policymakers to measure the socio-economic and environmental impacts of urbanization. It also allows cities to monitor the success and impact of sustainability interventions, for example on existing urban designs, infrastructures, policies, waste disposal systems, pollution and citizens' access to services (EC, 2015). Indicators that help governments and communities address sustainability goals provide data to guide policy-making and enable comparisons between local governments and regions (SCI, 2012). Shaping the city within a set of criteria and indicators has benefits not only in ensuring sustainability, but also in developing different ideas for city planners, local governments and decision makers, and in evaluating the suitability of currently carried out actions (Tuğaç, 2018).

There are many important international studies, starting with the 1933 Treaty of Athens and continuing with the 2016 Habitat III conference, that played a role in bringing urban sustainability indicators to the point they have reached today. Other studies include; UN United Nations (UN) Conference on the Human Environment (1972); UN Environment and Development Commission Our Common Future Report (1987); European Urban Charter (1992); UN Conference on Environment and Development (Rio Conference) and Agenda 21 (1992); Habitat II Conference-Istanbul Declaration (1996); Millennium Development Goals (2010); Sustainable Development Agenda and Sustainable Development Goals (2015). It would be appropriate to say that the first steps towards determining the indicators were taken with

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Agenda 21, which was adopted after the 1992 UN Conference on Environment and Development. One of the main objectives of this document is to develop indicators to define sustainable development processes, measure and monitor their performance. The first concrete step towards the development of urban sustainability indicators was taken when Voula Mega proposed the first set of indicators in the Aalborg Charter, which was adopted at the end of the *"First European Sustainable Cities and Towns Conference"* held in Aalborg, Denmark. It is stated in the Charter that urban sustainability indicators are an important guide in achieving social justice, sustainable economy and environmental sustainability in accordance with the carrying capacity of nature and the living conditions of individuals. Cities that have signed the Charter have also committed to engage in Local Agenda 21 processes and develop long-term action plans for sustainability. 4 years after the signing of the charter, the first sustainability indicator that can be used for medium-sized cities was developed under the leadership of Mega and Petersen under the roof of the *"European Foundation for the Improvement of Living and Working Conditions"*. (Mega ve Petersen, 1998; Tuğaç, 2018; Çolakoğlu, 2019; EEA, 2023).

Since 1998, many indicators, most of which are of European origin, have been developed by various institutions and organizations at international and regional levels. These indicators can be classified as global level, EU level, those developed by international organizations, country-specific and other. Today, there are a total of 23 indicators developed by different internationally recognized institutions and organizations on a global, regional and national scale. It seems that all these indicator systems that have been defined are aimed at identifying the problems of life in urban areas, developing policies in line with these problems, implementing these policies and monitoring the implementation. (Table 1).

**These are certification systems where sustainability criteria for settlements and communities are defined.*

Although some elements may differ in the indicators, basically all indicators show that "importance is given to the evaluation of natural resources in the conservation-use balance, climate and topography information is taken into account in planning and design, and strategies to reduce greenhouse gas emissions that cause climate change are developed." (Tuğaç, 2018). It is also noteworthy that in almost all indicators, "the presence of open green spaces " and "accessibility to these areas" are among the basic criteria.

The starting point of this study is the contribution of open green spaces, which are the main components of cities, to urban sustainability. Open green spaces are an important component of the city and a critical issue of urban planning. The spaces have a multifunctional contribution. These contributions can be grouped into three basic groups: contributions to urban ecology, economy and socio-cultural structure. These multiple contributions are detailed below.

Contributions to urban ecology: They ensure the preservation of the bond between urban landscape and natural landscape. They prevent habitat fragmentation. They contribute to the protection of urban biodiversity. During photosynthesis and respiration, plants absorb heavy metals and carbon from the air, include them in the process, and decompose them, making them more harmless. Thus, they help improve air quality. They also further decompose harmful substances in the soil with their roots. Thus, they are important in preventing soil pollution. They are important in preventing heat island. They provide thermal comfort in cities. They also create air corridors, affect the moisture balance in the air with their vital processes, and improve the urban microclimate. Roof gardens, vertical gardens and vegetal designs around buildings reduce building energy loss and support energy efficiency. They provide rainwater control. Thus, they ensure the nutrition of groundwater. These processes affect the hydrological cycle. They are also important in preventing disasters such as floods and floods as they increase groundwater permeability. They contribute to preventing erosion and sediment flow. They prevent noise pollution (Gül ve Küçük, 2001; Fam, et al., 2008; Georgi and Dimitriou, 2010; Lovell, 2010; Jorgensen and Gobster, 2010; Ignatieva, et l., 2011; Pincetl, S. and Gearin, E. 2013; Kabisch, 2015; Nero, et al., 2017; Rakhshandehroo, 2017; Demiroğlu et al., 2016; Demiroğlu et al. 2017; Chen, et al., 2019).

Contributions to the urban economy: Open green spaces provide many different economic contributions, from providing a source of income to reducing energy costs. In this context, the areas primarily contribute to increasing housing and land values. They reduce the energy consumption and costs of buildings. They reduce building-energy consumption with roof gardens and vertical gardens. They reduce infrastructure costs by providing natural and sustainable solutions. They increase the interception and infiltration of rainwater, reduce the risk of storm sewer overflows and floods, and minimize the disaster expenses of local governments. They contribute to employment by creating resources for tourism activities. It nourishes edible landscape areas and urban agricultural areas. They reduce public health costs. They support the use of environmentally friendly means of transportation. (such as scooter, bicycle use area). They help the natural decomposition of waste (Curran, 2001; Gül ve Küçük, 2001; Jim and Chen, 2006; Fam, et al., 2008; Philips, 2013; Zoest and Hopman, 2014; Cilliers, 2015, Karadağ, 2018; Donghyun and Seul-Ki, 2019; Ali, et al. 202; Fei et al., 2023).

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Contributions to urban socio-cultural structure: Socio-cultural contributions are contributions extending from the individual to the health and structure of society. The existence of the open-green spaces positively affects people's physical, psychological, mental and sociological health. In this context, its effects on attention deficit and obesity are very important. It is important in children's development. It is also important in increasing the health and social connection of older people. It affects social health by increasing social interaction. It is important for ensuring and improving social equality. By providing recreation services, it ensures quality use of free time. It reduces the crime rate. It offers a field of education and science. It improves the quality of life. It contributes to the continuity of cultural values by providing public venues for activities such as concerts and festivals. It provides a safe emergency meeting and shelter area in times of disasters and crises such as epidemics and earthquakes (Fam, et al., 2008; Jorgensen and Gobster, 2010; Lee and Maheswaran, 2011; Pincetland Gearin, 2013; Jennings, et al., 2017; Demiroğlu, et al., 2018; Javadi, et al. 2021; Lopez, et al., 2021; Li, et al., 2022).

In this context, the aim of the study is to provide information about urban sustainability indicators put forward by different countries and organizations internationally; and to examine the contributions of urban open green areas, which make significant contributions to the ecological, economic and social-cultural sustainability of cities, in achieving the goals of urban sustainability indicators within the framework of two basic indicators, one developed at the global and the other at the EU level.

2. MATERIALS and METHODS

The main material of the study consists of different sustainable city evaluation indicators in the world, which were developed as a result of the accumulation of international studies on sustainable cities (Table 1). In the study, the contributions of urban open green spaces to achieving urban sustainability indicators were evaluated on the basis of the "*United Nations Urban Indicators Guide*" (UN, 2004) and the "*European Foundation Urban Sustainability Indicators*" (Mega and Petersen, 1998).

Urban Indicators Guide; the guide focuses on quality of life and sustainability. The guide consists of 5 main objectives (Housing, Social Development and Poverty Alleviation, Environmental Management, Economic Development, Governance). (Urban Indicators Guidelines, 2004).

European Foundation Urban Sustainability Indicator; the indicator, created by the "*European Foundation for the Improvement of Living and Working Conditions*" in 1998 was developed to draw a common framework for medium-sized cities based on the commitments in the Aalborg Charter. Almost all topics and scopes that can be evaluated in the context of urban sustainability are included. This system, which consists of a total of 16 main indicator headings, includes nine environmental indicators, six social indicators and one economic indicator. The most important difference of this criteria system is that it includes the "Original Sustainability" category. This means that some sustainability practices are specific to a particular city (Mega and Petersen, 1998).

In the study, the multiple benefits provided by urban open green spaces to the city were evaluated as a contribution point/subject to sustainability. As a result of the evaluation, Table 2 was created within the scope of the literature. Each contribution is given a code in the table and 36 contribution codes were developed under 3 main titles. Then, sustainability indicators

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

(on the scale of sub-criteria) were examined on the basis of the contributions provided by open green areas, and "contribution codes" were given to each sub-criteria to be contributed. A (-) is added to the criterion for which no contribution is made (Table 2).

Table 2. Contribution points/topics of open green spaces to urban sustainability

<i>Ecological contributions(The spaces.....)</i>	<i>Code</i>
support biodiversity.	C1
retain and decompose heavy metals in the atmosphere.	C2
capture and decompose carbon in the atmosphere.	C3
decompose waste/pollutants in the soil.	C4
prevent heat island and provide thermal comfort.	C5
improve urban microclimate.	C6
reduce energy usage.	C7
feed ground water.	C8
provide rainwater management.	C9
contribute to the prevention of disasters such as floods.	C10
reduce erosion and sediment flow.	C11
contribute to preventing noise pollution.	C12
<i>Economic contributions (The spaces.....)</i>	<i>Code</i>
increase the housing market.	C13
increase the land market.	C14
reduce energy consumption cost.	C15
provide employment.	C16
reduce infrastructure costs and maintenance.	C17
reduce transportation costs.	C18
support sustainable transportation.	C19
reduce healthcare costs.	C20
reduce recreation expenses.	C21
provide economic contribution by turning into a tourism resource.	C22
support the economy from different aspects, such as edible landscapes and urban agriculture.	C23
reduce the costs of combating and adapting to climate change.	C24
reduce disaster-related expenses.	C25
<i>Socio-cultural contributions (The spaces.....)</i>	<i>Code</i>
positively affect human health.	C26
positively affect child development.	C27

increase social interaction.	C28
improve social equality.	C29
positively affect public health.	C30
provide recreation services.	C31
reduce the crime rate.	C32
support education and science.	C33
increase the love of nature.	C34
supportcultural sharing.	C35
provide safer living spaces in times of disaster and crisis.	C36

3. FINDINGS

In the "United Nations City Indicators Guide", there are basically 5 targets and a total of 19 sub-targets that feed these targets. It has been concluded that the contribution of open-green spaces to the shelter goal is ecological and economical, the contribution to the goal of social development and poverty alleviation is socio-cultural, and the contribution to the environmental management goal is ecological, economic and socio-cultural. Additionally, when the table is examined, it has been seen that the contribution of the spaces to the economic development target is of economic weight, and to the governance goal is of socio-cultural weight (Table 3).

Table 3. UN Urban Indicators Guide (UN, 2004)

GOALS	Contribution Quality of Open-Green Spaces		
	<i>Ecological</i> (code no)	<i>Economic</i> (code no)	<i>Socio-cultural</i> (code no)
1. SHELTER			
1.1. Supporting the right to adequate housing <i>(Fixed structures, excessive density, right to adequate housing, ratio of house and rental costs to income)</i>	-	-	-
1.2. Ensuring the security of property rights <i>(Property right, construction with official permission, eviction by court decision)</i>	-	-	-
1.3. Equal access to loans (Housing finance)	-	-	-
1.4. Equal access to land (Ratio of land prices to income)	-	13,14	-
1.5. Supporting access to basic services <i>(access to safe water, access to advanced treatment, connectivity to services)</i>	2,4,8,9	-	-

September 14-15, 2023, Naples, Italy

2. SOCIAL DEVELOPMENT AND FIGHTING POVERTY

2.1. Providing equal opportunities for a safe and healthy life (<i>mortality rate under 5 years of age, murders, violent incidents in the city, HIV incidence</i>)	-	-	28,29,32
--	---	---	----------

2.2. Supporting social integration and disadvantaged groups (<i>Poor households</i>)	-	16,23	28,29
--	---	-------	-------

2.3. Ensuring gender equality in human settlements (<i>Literacy rate; Women's participation in social life; Education participation rate; Women council members</i>)	-	-	28,29,33
--	---	---	----------

3. ENVIRONMENTAL MANAGEMENT

3.1. Supporting geographically balanced settlements (<i>Urban population growth; Planned settlements</i>)	1-12	13-25	26-36
---	------	-------	-------

3.2. Effective management of water supply and demand (<i>price of water; water consumption</i>)	2,4,8,9	17,24,25	-
---	---------	----------	---

3.3. Reducing pollution in the city (<i>Wastewater treatment; solid waste storage; regular solid waste collection</i>)	2,3,4,8,9,11	-	-
--	--------------	---	---

3.4. Preventing disasters and rebuilding settlements (<i>Disaster prevention and mitigation tools</i>)	9,10,11,12	24,25	33,36
--	------------	-------	-------

3.5. Effective and environmentally friendly transportation systems (<i>Journey time; transportation types</i>)	3	18,19	-
--	---	-------	---

3.6. Supporting mechanisms in line with the preparation and implementation of Local Agenda 21 (<i>Supporting mechanisms in line with the preparation and implementation of Local Environmental Plans</i>)	1-12	13-25	26-36
---	------	-------	-------

4. ECONOMIC DEVELOPMENT

4.1. Strengthening small and micro-scale enterprises, especially those developed by women (<i>informal workers</i>)	-	15,22,23	-
---	---	----------	---

4.2. Supporting public-private partnerships and employment opportunities (<i>Urban production; unemployment</i>)	-	15,22,23	-
--	---	----------	---

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

5. GOVERNANCE

5.1. Promoting localization and strengthening local governments (<i>Local government revenues; local distribution of responsibility</i>)	-	-	-
5.2. Supporting civic participation (<i>Citizen participation; voter participation; civil organizations</i>)	-	-	28,29,35
5.3. Ensuring transparent, accountable and effective governance in cities, towns and metropolitan cities (<i>Accountability</i>)	-	-	-

It has been concluded that the contribution of open-green spaces to the 16 basic indicators included in the "European Foundation's Urban Sustainability Indicators" is greater in the ecological field, followed by economic and socio-cultural areas, respectively (Table 4).

Table 4. European Foundation's Urban Sustainability Indicator (Mega and Petersen, 1998).

INDICATORS	<i>Contribution Quality of Open-Green Spaces</i>		
	<i>Ecological (Code no)</i>	<i>Economic (Code no)</i>	<i>Socio-cultural (Code no)</i>
1. Global Climate Indicator (GCI) (<i>Emitted total CO₂, CH₄, N₂O and CFCs and halons.</i>)	2,3,5,6	-	-
2. Air Quality Indicator (AQI) (<i>Number of days per year on which alarm levels are exceeded and traffic circulation is stopped.</i>)	2,3,5,6	-	-
3. Acidification Indicator (AI) (<i>SO₂ / hectare, NO₂ / hectare, NH₃ / hectare</i>)	4	-	-
4. Ecosystem Toxication Indicator (ETI) (<i>Emitted quantities of cadmium, polyaromatic hydrocarbons, mercury, dioxin, epoxyethane, fluorides and copper. Emitted radioactive substances</i>)	4	-	-
5. Urban Mobility Indicator (UMI) or Clean Transportation Indicator (<i>Urban Mobility Equation (Umeq) = Travel kilometers made by non-environmentally friendly vehicles (private cars, etc.) / number of urban residents</i>)	-	18,19	-
6. Waste Management Indicator (WMI)	4	-	-

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

(Waste disposed of by incineration or in controlled landfills and in uncontrolled landfills; waste reused or recycled)

7. Energy Consumption Indicator (ECI) 5,6,7 15,24 -

(Consumed energy according to the source of production (renewable energy, electricity, petrol, gas-oil, heavy fuel oil, natural gas, carbon and wood).)

8. Water Consumption Indicator 8,9,10 24 -

(Water from recycling and used mainly for maintenance of public and green spaces is to be subtracted.)

9. Nuisance Indicator (DI) 4,12 - 26,30

(It is essential to have a subindicator for the % of the population seriously affected by one of the above factors)

10. Social Justice Indicator (SJI) - - 27,28,29,30,32

(It is also essential to have subindicators for vulnerable groups of population (youth, women, the handicapped and long-term unemployed)

11. Housing Quality Indicator - - -

(The number of homeless in percentage of the inhabitants and of those who might become homeless.)

12. Urban Safety Indicator (USI) - - 28,32,35

(It is essential to have a subindicator for the total percentage of irreversible long-term injuries.)

13. Economic Urban Sustainability Indicator (ESI) - 17,24,25 -

(City revenues (total individual income), environmental expenditures (garbage, sewage, transportation, etc.), pollution expenditures (water, air, soil))

14. Green, Public Space and Heritage Indicator (GPI) - - 31,35

(% of green spaces needing improvement/total surface of green space. % of heritage spaces in need of improvement/total surface of heritage space. % of public spaces (including heritage sites) in need of improvement/total surface of public space.)

15. Citizen Participation Indicator (CPI) - - 28,29,35

(The total % of the population active in local elections and participating in associative life.)

16. Unique Sustainability Indicator (USI) (Indicator to be defined by each city according to its uniqueness (i.e. unique climatic and local conditions) or the planning of a unique once-in-a-lifetime event.	1-12	13-25	26-36
--	------	-------	-------

4. CONCLUSION ve RECOMMENDATIONS

Today, the basis of many environmental problems is the intense human activities carried out in cities that have lost the balance of protection and use. For this reason, cities constitute the focal point of studies on sustainability. It is seen that urban sustainability indicators have been developed in order to find solutions to many ecological-economic-social-cultural-managerial problems that have emerged in cities that have grown uncontrolled and unrestrained, especially since the 2000s. These indicators are important tools in measuring and evaluating the performance of cities in many areas mentioned above. The most important common criterion in these indicators is the open-green space assets of cities and the accessibility of these assets.

In this study, where the contributions of open green areas to achieving the goals of two basic urban sustainability indicators are interpreted, it is concluded that open green areas contribute to many areas of ecological, economic and social-cultural sustainability of cities. These contributions will be guaranteed by considering open-green areas as components of green infrastructure systems, evaluating these components on the basis of sustainable urban planning, and questioning the integration into other urban plans along with the presence of green infrastructure plans in sustainability indicators. However, it is very difficult to reveal these contributions in a quantitative way. This situation makes it difficult to clearly demonstrate the direct effect of the contributions on the indicators. In addition, in this process, it is extremely important to evaluate the ecological and economic contributions of green areas as well as their social-cultural contributions equally. In this regard, studies on the development of quantitative evaluation methods in the field of landscape economics should be concentrated.

ABSTRACT

Maintaining urban sustainability has been one of the urban planning and design agendas in recent years. Rapid and unplanned city expansion, which brought losing green spaces caused the necessity of ensuring urban sustainability for human habitability (quality of life). It didn't take long for city planners to understand the significance of equal access to natural resources as well as their protection and management in cities, in line with the idea of sustainable development. In order to increase environmental sustainability and human quality of life, green infrastructure refers to a range of technologies, goods, and applications that make use of natural systems or manufactured systems that resemble natural processes. The primary source of ecosystem services that humanity receives from the biotic environment is green infrastructure. Maintaining and developing the Green infrastructure to optimize the supply of ecosystem services, therefore, requires deliberate planning. Green infrastructures provide lots of economic, environmental, and social benefits in the cities, such as Health-promoting, Reducing the effect of the highest sound level, Providing diversity in spatial arrangement, Providing urban aesthetics, Providing a range of ecosystem services and protecting biodiversity in urban settings, and so on. The aim of this paper is to reveal the unequal distribution of green infrastructure in cities, the impact of the problems in accordance with losing infrastructure in the cities, their importance, and what needs to be done.

Keywords: Urban Design, Urban Planning, Green Infrastructure, Green Cities, Ecological Design

1. INTRODUCTION

According to Grimm et al. (2008), cities both greatly influence and are extremely vulnerable to planetary change. Urban infrastructures that are aging and resource- and energy-intensive are becoming more vulnerable to extreme weather events and other global changes.

Cities throughout the world are subject to a variety of risks that are influenced by variables such as rising urban population and climate change (IPCC, 2008). Climate change and urban development are intimately intertwined. Reducing sensitivity to these changes is the main goal of adaptation to climate change (Shirgir et al., 2019). According to the IPCC (2012), climate change will likely result in an overall rise in temperature, more frequent heat waves and the exacerbated heat island effect, a change in the variability of precipitation regime with an increase in high precipitation and flood events, a decrease in the quantity and quality of water resources, disruptions to agricultural production that put food security at risk, a loss of biodiversity, and a decline in the aesthetic and recreational value of the landscape. The capacity for self-organization, the capacity to adapt to stress, and the ability of a system to absorb disruptions while retaining the fundamental structure and functional procedures are all examples of resilience (IPCC, 2008). Climate resilience is one dimension of resilience. Climate

resilience—a sort of urban ecological resilience that encompasses adaptation to and mitigation of the risks and negative effects of climate change has many different dimensions. In this case, urban green infrastructure is helpful in decreasing the effects of climate change in cities and boosting climate resilience. Since the 1970s, cities have been developing with the idea of green infrastructure (GI). The Boston "Emerald Necklace," which was described as a "complex multifunctional environmental design solution" that connected areas by green corridors (Engleback, 2009, p24), was the first example of urban planning and nature conservation/environmental awareness coming together.

Public parks were originally classified as a type of urban infrastructure in 1996 under the heading "infrastructure as a park and green space." According to Bianoci et al. (2018), "Green Infrastructure" (GI) is defined as an ecosystem or network of ecosystems with distinct components, needs, functions, and services, as well as a connected system of green space that preserves the values and functions of natural ecosystems while also benefiting human populations. The European Union saw green infrastructure (GI) as a clever response to the demands of the present. One of the solutions for coping with climate change, as well as for fostering and advancing climate resilience in cities, is urban green infrastructure.

Since the 1970s, cities have been developing with the idea of green infrastructure (GI). The European Union saw green infrastructure (GI) as a clever response to the demands of the present. One of the solutions for coping with climate change, as well as for fostering and advancing climate resilience in cities, is urban green infrastructure. According to Demouzere et al. (2014), GI generally refers to green roofs, permeable green surfaces, green walks and streets, urban forests, public parks, community gardens, and urban wetlands.

Given their tendency to be densely populated and impermeable, cities require as much green infrastructure as feasible. The term "green infrastructure" refers to anything that helps absorb, delay, and treat rainwater in an urban setting to reduce flooding and pollution downstream. This includes everything from parks to street trees and green roofs. Additionally, green infrastructure produces oxygen, absorbs carbon, and supports biodiversity (Hussein et al, 2020).

2. MATERIALS and METHODS

The most important question that may arise here, is Why should green infrastructure get involved in the urban planning and development. What is the problem?. This research contains three steps. The following section offers the research questions and a review of the literature related to the concept of urban green infrastructure. The third section of the paper focuses on the types of urban green infrastructures based on the literature review research. The last section is devoted to a general evaluation and conclusion (Figure 1).

Figure 1. Research Process (by the author).

3. FINDINGS and DISCUSSION

According to The Assian Development Bank (2014) In the nations that have had the least impact on global warming and climate change, low-income and middle-income populations are currently experiencing direct and indirect effects of climate change. Climate change will undoubtedly have the greatest impact on the lower income classes (Asian Development Bank, 2014).

This vulnerability is exacerbated by population pressure. By 2050, two-thirds of the world's population will live in cities, and many countries already have a high urbanization rate. Today's cities are developing toward more resilient, self-sustaining systems to maintain quality of life for expanding urban populations while maintaining within safe planetary biophysical constraints (Röckstrom et al. 2009) (Reynolds et al, 2019).

The quality of life, the state of the economy, and social stability are all negatively impacted by urbanization and climate change. Climate change mostly affects the regions with high concentrations of people, businesses, and infrastructure (green-gray). Due to their physical location, some metropolitan regions are also more susceptible to increased effects of climate change, such as high temperatures, rising sea levels, and fluctuating precipitation. A city's rapid growth will replace greenery with hard construction surfaces, amplifying the consequences of climate change (IPCC, 2008). As a result, precipitation is decreased and temperatures rise. To reduce the adverse effects of climate changes in the cities there is an urgent need to prepare and implement Design Guidelines for climate-responsive urban green infrastructure. Anticipating potential effects of climate change on green infrastructure and modifying management practices accordingly are necessary for proactive planning for climate change.

 University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

According to Klemm (Klemm et al., 2017) the guideline can be prepared in three scales, city, park and Street. At the same time all these parameters should be understanding, applicability, and viability.

4. CONCLUSION and RECOMMENDATIONS

In cities, green infrastructure offers numerous economic, environmental, and social advantages, including; providing urban beauty, improving health, reducing the impact of the loudest noise, providing variety in spatial layout, conserving biodiversity in urban areas and providing a variety of environmental benefits.

Green infrastructures can be implemented in different scales of design in cities, such as green walls, green roofs, and green public spaces, permeable green surfaces, green walks and streets, urban forests, public parks, community gardens, and urban wetlands (Demouzere et al., 2014).

Table 1. The Advantages of Green Infrastructures (Parker and Zingoni de Baro, 2019).

Advantages				
Welbing and Health Advantages	Environmental Advantages		Economic Advantages	Social Advantages
Elevated Mental Mood	Sequestration of carbon	of	Cheaper in capital costs than alternatives	a stronger sense of community
Elevated Physical Mood	Expansion of biodiversity	of	Cheaper in terms of operational costs than alternatives	Enhanced amenities

ABSTRACT

In recent years, the urbanization trend resulting from the population's migration towards urban environments has put pressure on open-green spaces. The inadequacy of open-green spaces due to the increase in physical structures leads to climate changes such as urban heat islands. The climate-related changes in urban ecosystems also affect urban biodiversity. Therefore, the plant species used in open-green areas have become more important to reduce the impact on urban biodiversity from these changes. New landscape design approaches should be sought to address the expected drought problem due to possible climate changes. Using drought-resistant, natural plant species and edible plants in urban spaces can provide economic, ecological, functional, and aesthetic benefits, as well as contribute to urban biodiversity. Climate change will be determined for the year 2050 with the UrbClim software model. According to the result of this, the plant list for the urban space will be determined. While there are many studies on urban biodiversity, there are relatively few studies on biodiverse cities. In a study focused solely on road trees, Liu and Flik (2021) examined the concept of biodiverse cities as a friend to biodiversity. This paper aims to explore the concept of biodiverse cities using natural and edible plant species in urban open-green spaces, such as residential areas, urban transportation corridors, city parks, and urban public gardens. The criteria for biodiverse cities will be established based on these two concepts. The ratios of these drought-resistant and extreme climate-tolerant plant species to other plant species used in urban open-green spaces will be determined and methodologically based on plant species ratios and densities. Areas with a plant species count exceeding the established ratio will be designated as biodiverse cities. Strategies will be proposed to raise awareness and implement this concept at the local, national, and global levels. This paper aims to provide data to the literature and practice as the first study on the criteria for biodiverse cities.

Keywords: Urban Biodiversity, Biodiverse Cities, Natural Edible Plant Species, Drought-Resistant Landscaping.

1. INTRODUCTION

In the UN development report, it is stated that by 2050, nearly 70% of the world's population will start living in urban areas. As a result, urbanization movements resulting from the increasing urban population in the world and in our country have led to a series of challenging environmental issues in urban ecosystems. Especially with the decreasing agricultural areas and green spaces, urban heat island formation threatens urban biodiversity. Due to inadequate attention to natural and ecological thresholds in physical development, cities fail to reap the difficult benefits of natural ecosystems, making them vulnerable to disasters. Climate change has begun to negatively affect urban areas in particular:

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Scientists have indicated that July 2023 could be the hottest month since the industrial revolution, with an absolute global average temperature increase ranging from 1.3 °C to 1.7 °C. It is emphasized that the consequences of inaction against global warming are unacceptable and that carbon emissions need to be reduced urgently, and cities, infrastructure, and healthcare systems need to be redesigned for climate change (URL, 1). According to a press release in July 2023, the U.S. government has decided to allocate 1 billion dollars for tree planting to combat climate change.

According to the Intergovernmental Panel on Climate Change (IPCC), global temperatures have already risen by 1.1°C and are progressing towards 1.5°C. Following the Paris Climate Agreement (COP21) held in 2015 with the participation of 194 countries and the UN Climate Change Conference (COP26) held in Glasgow in 2021, the 27th Parties to the UN Framework Convention on Climate Change was held in Egypt in 2022 with the participation of 190 countries. As a result of this meeting, it was decided to prepare action plans to keep global climate change below 1.5 degrees by the end of the century (URL 2, 2023).

Urban Biodiversity

Urban biodiversity is defined as the diversity of flora and fauna in different habitats within urban ecosystems. According to Müller et al. (2013), urban biodiversity refers to the "diversity or richness and abundance of living organisms (including genetic diversity) and habitats found in the environment and its surroundings. Species vary from rural areas to urban cores. Humans have a long history of transporting plant species and influencing local biodiversity. Survival and reproduction of wildlife species are directly related to the presence of urban landscape areas. Plants and animals in cities interact with the existence of social and ecological systems, often creating unique biotic communities unique to that city.

Various research has revealed that biological diversity within cities is higher than in the surrounding areas. Larger urban landscapes have been found to have more non-native species than smaller urban landscapes (Pyšek et al., 2004).

However, rapid changes in physical structures in cities, the loss of open and green spaces, and climate change are increasingly putting urban biodiversity under more pressure.

Urban ecosystems, being warmer in cold regions, benefit biodiversity with longer plant growth, protected building environments, local irrigation, moisture presence, and conscious or unconscious food availability. Environmental pollution and the destruction of natural habitats threaten urban biodiversity. According to Sukopp and Wurzel (2003), despite ecological and socio-economic factors affecting plant cover in urban areas, many non-native invasive species that colonize (or become naturalized) in cities come from warmer regions and benefit from more favorable climates.

Urban tree species are important components of floristic diversity. In a study, it was emphasized that as the number of tree species increases, ecosystem resilience increases, and a single tree species should not exceed 10-20% of the total tree species (Kendal et al., 2014).

Trees and shrubs planted in various areas in urban spaces are important natural elements that connect people to the biosphere (Liu et al., 2021). Urban plant diversity, consisting of natural/native species, brings many advantages, such as supporting urban greenery sustainability, sensitivity to climate change, supporting wildlife and native fauna, and low maintenance costs.

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

The use of fruit-bearing plant material is more common in private gardens (single-family homes, housing, collective housing, some public institution gardens, etc.) in our country (Dikmen and Yılmaz, 2021). Fruit trees in urban environments contribute to visual landscape quality with flower and fruit colors, autumn leaf color changes, and are important building blocks that support wildlife (birds, bees, butterflies, some insect species, etc.) ecologically and economically. In a study (Demir and Aydın, 2020), it was found that in terms of biodiversity, areas with intense human activities have more insect diversity compared to areas with low human activities.

Urban open-green areas are the most important building blocks for regulating climate/heat island formation, reducing its negative effects, and increasing the resilience of cities in the face of increased urbanization (Figure 1). These areas undertake many vital tasks such as ecological, aesthetic, economic, socio-psychological, recreational, and contributing to biodiversity (Yılmaz et al., 2021; Alves et al., 2022; Balany et al., 2022; Quyang et al., 2023; Young et al., 2023).

A New Concept: Bio-Friendly City (BIOCITY)

The use of fruit-bearing plant species in urban environments is a critical criterion for creating bio-friendly cities. The concept of a bio-friendly city was first introduced in a study conducted in China (Liu and Slik, 2021). In this research, street trees in 59 Chinese cities were considered as natural species and fruit-bearing trees, and it was concluded that these plants were not adequately represented in urban areas.

In this study, the concept of a BIOCITY, particularly in the context of urban biodiversity's importance and sustainability in the face of climate change scenarios, aims to provide a resource for biological diversity research.

BIOCITY covers the analysis of open-green areas such as urban spaces, street trees, public institution gardens, residential gardens, urban woodlands, cemeteries, squares, sports fields, and their vicinity. A suggested form has been created for implementation in each area.

In any urban open-green area, the Biyodost settlement criteria recommendation form includes the following analyses:

As Bio-Friendly City criteria recommendations:

The number of natural species used for each land use will be considered, along with the number of fruit-bearing species.

The total number of plant species for each land use.

The ratio of one tree species to the total number of tree species in each land use.

The age of planted vegetation in each land use.

The size of the area.

The ratio of green areas to impermeable surfaces.

Positive ecosystem components.

Negative ecosystem components.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Each of the above criteria is assigned a score out of 100 based on its contribution to biodiversity according to the specific characteristics of the area. Settlements that score above 60% are defined as Biyodost.

Figure 1. Urban green spaces contribute to urban biodiversity

2. CONCLUSION and RECOMMENDATIONS

To minimize the harms of rapid urbanization, world leaders agreed upon 17 global goals in 2015 under the title of "Sustainable Cities and Communities" by the United Nations. Among these main goals, particularly, sustainable development has brought significant pursuits such as promoting healthy and quality living, accessible and clean energy, sustainable cities and communities, climate action, life below water, and life on land (URL 3).

The invasion of exotic plants into cities, rapid physical changes in urban ecosystems, and resulting environmental pollution, as well as the fragmentation of ecological corridors/habitats with changes in topography, are all leading to a decreasing resilience in urban biodiversity. Urbanization fragments or eliminates natural vegetation, leading to habitat loss and isolation. Altering the spatial arrangement and heterogeneity of landscapes disrupts ecological pathways (Müller et al., 2013; Aznarez et al., 2022).

The rapid urbanization and global biodiversity loss necessitate new research that provides information on policies, management, and protection in urban ecology (Knapp et al., 2021). It is assumed that natural species will provide a broader range of biodiversity benefits (Berthon

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

et al., 2021). It is known that urbanization changes local conditions and can make urban living areas unsuitable for native plant species (Sjöman et al., 2016).

With Bio-Friendly City:

The concept of a biodiversity-friendly city in urban landscape approaches against climate change scenarios can be a new approach.

Although the components/criteria of the Bio-Friendly City concept have been determined, the development of applications through this criterion can be achieved through field applications.

Strategies for urban open-green areas to meet the Bio-Friendly City criteria can be determined by decision-makers, subject experts, and public participation in cities.

For other cities in our country, this concept can be popularized by applying it to any urban green area, and by promoting it, it can gain brand value.

In this regard, a study on the concept of a biodiversity-friendly city (Bio-Friendly City) has been conducted for the first time in this work. The fact that no similar study has been conducted in our country or abroad makes this idea or concept unique.

The concept of a Biodiversity-Friendly City (Bio-Friendly City), which will be discussed for the first time through this study and the fact that it will be discussed in the scientific community and public opinion as a brand value for cities in our country and worldwide, is also an important step in terms of developing strategies.

In conclusion, in our present day when we are beginning to experience all the negatives of climate change, there is a need for new approaches for sustainable urban ecosystems. The importance of urban open-green areas for urban health, ecology, aesthetics, economics, and sociology has increased. New concepts like **BIO-FRIENDLY CITY** need to come to the forefront, and different disciplines should come together for their implementation, initiating the first applications to develop this concept.

A CONCEPTUAL REVIEW ON SECOND HOME TOURISM

Res. Asst. Yusuf Çağrı Türkseven* (ORCID: 0000-0002-8491-3899)

Mersin University, Faculty of Tourism, Department of Tourism Guidance, Mersin-Türkiye

Email: turksevcagri@mersin.edu.tr

ABSTRACT

Tourists' reasons for traveling create various types of tourism. Houses where individuals spend their leisure time outside their permanent residence in order to have fun, rest and get away from stress are called second homes. The socio-economic events that occur during the temporary stays in second homes have brought prominence to the concept of second home tourism. Unlike other tourists, second home tourists visit the same region to be together with the same people during their stays. Therefore, they are considered as marginal tourists. Second homes are studied from various perspectives in the disciplines of architecture, urban planning, geography, and tourism. The main objective of this study, designed through qualitative research method, is to establish a theoretical framework related to second home tourism. In addition, the sub-objective of the research is to assess the social, economic, and environmental impacts of second home tourism and to develop recommendations based on existing studies. Within this framework, the concepts of second home and second home tourism have been thoroughly explained. Document analysis and literature review have been conducted in line with the defined objectives. According to the findings of the study, second home tourism is mostly studied in geography and tourism disciplines. Studies have shown that while second homes are important for the continuity of economic benefits derived from tourism activities; However, in terms of socio-cultural impacts, they may have negative effects on the local community. Furthermore, it has been determined that in areas where second homes develop without proper planning, they exert pressure on the environment and infrastructure. On the other hand, second homes, which hold a significant place within domestic tourism, have become the most preferred tourism type during the COVID-19 pandemic. As a result of the research, in areas that have not benefited from mass tourism investments but are rich in natural resources, the development of planned second housing tourism and infrastructure works for this purpose are presented as recommendations.

Keywords: Second Home, Second Home Tourism, Literature Review.

1. INTRODUCTION

Tourism activities are essentially composed of temporary and non-commercial trips. Travel undertaken for tourism purposes has various economic, social, cultural, and environmental impacts (İçöz, et al., 2019). Tourists engaging in economic activities by spending money without the intention of earning during their travels hold a significant place in the economies of countries and regions. Tourism income generated from the expenditures made by tourists during tourism activities has positive economic effects, such as contributing positively to the balance of payments, assisting in the reduction of trade deficits, addressing foreign exchange constraints, and creating employment opportunities. Therefore, tourism activities hold a significant place in national policies (Kozak and Bahçe, 2009; Bahar, 2020).

TeMALab

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Tourism activities in Turkey began to develop from the 1950s onwards. The mass tourism movements (sun, sea, and sand tourism) that gained momentum in the 1960s further accelerated by the 1980s in Turkey. Particularly, the Tourism Incentive Law No. 2634, enacted in 1982, supported mass tourism movements. Tourist visits to Turkey have consistently increased over time, except during crisis periods. Recent tourism statistics reveal that, apart from the COVID-19 outbreak in December 2019, Turkey has witnessed an increase in both tourist numbers and tourism revenue (TUIK, 2021). During the COVID-19 pandemic, mass tourism activities came to a halt, and tourists shifted their focus from mass tourism to alternative tourism activities. In this context, there has been an increase in demand for second homes during the COVID-19 period (Zoğal and Emekli, 2020). As a result, during the COVID-19 pandemic, second homes have gained prominence in the revival of tourism activities, and there has been a growing emphasis on second home tourism (Zoğal et al., 2020).

The importance given to second homes has increased in Turkey, leading to the initiation of construction activities for second homes (Emekli, 2004). Starting from the 1980s, Turkey's building capacity began to increase in terms of second homes. As the number of individuals participating in tourism activities increases, there is also a growing interest in second homes (Cohen, 1974; Hilber and Schöni, 2020). In this context, second home tourism holds a significant place within the tourism industry today. Second homes are important not only within the scope of outbound tourism but also within the scope of domestic tourism (Kervankıran and Çuhadar, 2017). A significant portion of overnight stays in Turkey takes place in the homes of relatives, close acquaintances, and second homes (Mutlu and Avcıkurt, 2021). Therefore, the main objective of this study is to establish a theoretical framework for second home tourism. Additionally, the sub-objective of the research is to highlight the social, economic, and environmental impacts of second home tourism through existing studies and to develop recommendations.

2. CONCEPTUAL FRAMEWORK

In this section, the concepts of second homes and second home tourism are elaborately explained. Within this context, information is provided about the development process of second homes, and studies related to second home tourism in the fields of tourism and geography disciplines are examined.

2.1. The Concept of Second Homes

There are numerous definitions in the literature regarding the concept of second homes. According to Clout's (1971) definition, second homes are residential properties or apartment units owned by individuals that are used for short-term stays during specific periods of the year, excluding tourist facilities. According to Clout, the primary purpose of staying in second homes is to fulfill individuals' vacation needs. According to Manisa (2007), second homes are fixed properties built in destinations rich in natural and cultural resources, such as coastal areas, mountains, lakes, and thermal springs, outside of individuals' primary residences. These properties are used for vacation purposes during specific times of the year and are associated with tourism-related real estate investment. The concept of being associated with tourism, as mentioned in this definition, stems from the alignment of second home usage with the principles of leisure in tourism (Hall, 2014). In another definition, second homes are the residences to which individuals travel in order to escape the stress and chaos of daily life in their primary permanent residences (Emekli, 2014). Authors often define the concept of second homes as

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

residences located in areas near water sources, different from individuals' primary residences, and used during specific periods of the year to escape from daily life (Oğan and Yasak, 2021). Based on these definitions, we can list the characteristics of second homes as follows:

- Being located in areas rich in natural resources,
- Temporary use for tourism purposes,
- Possessing the characteristics of a fixed property,
- Being considered as real estate investment.

The term "second" used in the concept of second homes does not indicate a sequence. The primary reason for using the term "second" is that these homes remain vacant for a significant part of the year (Emekli, 2014). In other words, the term "second" does not denote a sequence of owned properties but rather refers to a residence used at a specific time, excluding the primary permanent residence (Zoğal and Emekli, 2018). When reviewing the literature, it can be observed that second homes are classified and labeled based on their seasonal characteristics and structural conditions. In English, terms like "summer houses," "second housing," and "second home" are used, while in Turkish, they are referred to as "yazlık evler" (summer houses), "kır evleri" (countryside houses), "çiftlik evleri" (farmhouses), and "rekreasyonel konutlar" (recreational houses) (Müller, 2002; Okuyucu and Somuncu, 2016). Table 1 demonstrates the classification of second homes.

Table 1. Classification of Second Homes

Type	Structure	Building/Vehicle
Permanent	Houses and Apartments	Remote Country Houses and Homes Second Village Houses Apartment Buildings
Semi-Portable	Camps	Vans/Mobile Homes Recreational Vehicles Tents Caravans
Portable	Boats	Sailing Boats

Source: (Hall and Müller, 2004: 5).

As seen in Table 1, second homes can have different types and characteristics. However, the areas where second homes are developed generally exhibit similar features. These regions often include:

- Areas rich in natural resources easily accessible to major urban centers,
- Coastal regions and their vicinity,
- Highlands with tourist attractions (Emekli, 2014).

2.2. Second Home Tourism

Tourism types are formed based on the purpose of travelers' trips. In this context, interactions arising from travels to second homes contribute to the emergence of second home tourism in the visited destinations. These trips to second homes fulfill the conditions included in the definition of tourism (Müller, 1999: 33). Unlike other tourists, individuals participating in

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

second home tourism travel to the same destination to spend time with the same people. Therefore, these tourists do not possess the motivation to seek experiences or be in the company of different individuals, as is the case with other tourists (Cohen, 1974). Consequently, second home tourists occupy a position between being locals and tourists (Müller, 1999). In tourism-oriented second home usage, the travel duration between individuals' primary residence and the second home holds significance (Kauppila, 2010). The travel distance between individuals' primary residences and their second homes, where they can spend their weekends, ranging from 100 km to 250-400 km, is significant in terms of the usage of second homes. This is due to the fact that the frequency of second home usage decreases after 200 km (Lipkina, 2013). When the travel distance exceeds 400 km, the rate of second home ownership also declines (Okuyucu and Somuncu, 2015). However, for second home tourism to develop in areas beyond 400 km, these regions need to have more abundant natural resources. Therefore, the development of second homes located by the sea or lakeshores with rich tourism products and those in winter tourism areas is not influenced by the distance factor (Kauppila, 2009). Second homes in Turkey are typically constructed in areas with high tourism appeal in the Aegean and Mediterranean regions. Additionally, there are second homes suitable for weekend usage in locations close to the city center of Istanbul (Gökdeniz, 2014). In this context, second homes are significant for domestic tourism.

Domestic tourism activities encompassing travel for tourism purposes within the political boundaries of a country hold significant importance in many countries around the world for reducing interregional development disparities and promoting balanced development (Turner and Reisinger, 2001). In Turkey, second home tourism plays a pioneering role in invigorating domestic tourism. Due to their seasonal usage, second homes commonly referred to as "yazlık" (summer houses) are prominent in terms of overnight stays in Turkey (Mutlu and Avcıkurt, 2021). In this context, it can be stated that second homes are an indispensable element for domestic tourism (Jackson, 1986).

2.3. Development Process of Second Home Tourism

Second homes have been frequently used for various purposes throughout history. For instance, in ancient times, affluent individuals would satisfy their accommodation needs in their second homes during their travels to different destinations (Gomes et al., 2017). In countries like Sweden, the United Kingdom, and France, cities such as Stockholm, London, and Paris have second homes that affluent individuals have used at various times. In Greece, individuals belonging to the upper class have acquired second homes for tourism purposes.

In its contemporary sense, second home tourism has developed in the vicinity of large cities. After World War II, individuals' prosperity increased, and there was a growing demand for second homes driven by the understanding of tourism (Huang, 2003; Bakırcı, 2007). Additionally, the desire to escape the stressful urban life (Adamiak et al., 2015) and the ability for foreigners to purchase properties in Turkey under the framework of European Union (EU) harmonization laws (Manisa, 2007) have contributed to the popularity of second homes.

In Turkey, following the transition to a free market economy after the 1980s, second homes have been utilized as a means to support development (Emekli, 2014). During this period, advancements in transportation and the widespread use of automobiles accelerated individual tourism movements, leading to an increase in the use of second homes for leisure purposes in tranquil areas near large cities. On the other hand, in the 1990s, haphazardly constructed second

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

homes led to issues of unused capacity and exerted pressures on the environment. Subsequently, the 1999 Gölcük earthquake and the 2001 economic crisis reduced the demand for second homes in Turkey. However, after 2003, the legal regulation allowing foreigners to purchase properties under the EU harmonization laws and the reduction of housing interest rates revitalized the demand for second homes (Emekli, 2014; Manisa, 2007).

2.4. Review of the Literature on Second Home Tourism

Second homes have various social, economic, and environmental impacts, which is why they are studied in different disciplines. In this context, studies on second homes and second home tourism are extensively conducted in geography and tourism literature. Studies conducted within the field of geography provide a comprehensive understanding of tourism (Hall and Page, 2012). In this context, it can be said that geography and tourism disciplines share similarities in their scope of study. When examining geographical studies related to second home tourism, it becomes evident that the selection of areas for the development of second homes places significant importance on the geographical characteristics of the region (Emekli, 2014). Therefore, the areas where second homes are situated need to be geographically suitable. Within this scope in a qualitative study investigating the reasons for choosing the Urla district of İzmir as a second home area, findings revealed the attractiveness of the region in terms of natural resources, affordable housing prices, and its proximity to İzmir (Zoğal and Emekli, 2018). The second home owners included in the research evaluated the economic vitality provided by second homes as a positive feature. However, causing spatial clustering and exerting pressure on the environment were considered negative attributes.

In another study conducted by Yasak and Doğan (2018), the reasons for the development of second homes in Silivri were analyzed. As a result of the study, it was revealed that Silivri's location on the main transportation lines and its close location to Istanbul accelerated the development of second homes in Silivri. Tourism activities also develop in the areas where second residences develop. Studies conducted in this context are included in the tourism discipline.

In the tourism discipline, second homes have been addressed in terms of different topics. These topics are generally; evaluation of second homes in tourism (Önder et al., 2010; Manisa and Görgülü, 2008; Kozak and Duman, 2011), perceptions of local people about the development of second home tourism and foreigners' second home acquisitions (Avcıkurt et al., 2021; Karakaya and Turan, 2006; Öztürk et al., 2007; Kadı, 2014; Baltacı, 2011), socio-economic impacts of second homes (Oğan and Yasak, 2021; Marjavaara, 2007; Ünlüönen and Çimen, 2010; Velvin et al., 2013), meanings attributed to second homes after the COVID-19 pandemic and motivations for second home ownership (Clout, 1972; Jackson, 1986; Chaplin, 1999; Lipkina, 2013; Turksoy, 2021). Upon reviewing the literature, it is observed that the conducted studies predominantly employ quantitative methods and utilize survey designs (Avcıkurt et al., 2021; Baltacı, 2011; Oğan and Yasak, 2021; Okuyucu and Somoncu, 2016; Ünlüönen and Çimen, 2010; Öztürk et al., 2007). In these studies, surveys have been used as the data collection method. The scarcity of studies that comprehensively investigate second home tourism from the perspectives of local communities, destinations, and second home owners using qualitative methods is noteworthy (Zoğal and Emekli, 2018). Therefore, there is a need for in-depth studies designed with qualitative methods to be conducted on second home tourism.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

According to the findings of studies in the literature, it is recommended that second homes should be developed not only in coastal areas but also in regions abundant in natural resources. The development of second homes in these areas will foster economic vitality and alleviate unemployment issues in the regions (Önder et al., 2010). Furthermore, the utilization of second homes in tourism will contribute to an increase in the accommodation sector's capacity (Manisa and Görgülü, 2008; Kozak and Duman, 2011).

When examining the results of studies investigating the effects of foreign individuals acquiring second homes, it has been determined that such acquisitions can create multiplier effects on the economy. On the other hand, it has also been found that foreign individuals acquiring second homes can lead to certain socio-cultural drawbacks. These drawbacks include the unintended use of second homes, economic leakage issues, and tax losses (Kadı, 2014). Conversely, foreigners purchasing real estate in Turkey can have a positive impact on the country's image (Öztürk and Bayram, 2021). Consequently, it is suggested that this can lead to an increase in the number of tourists and tourism revenues.

When the participation of individuals in second home tourism and their motivations for acquiring a second home are analyzed; the prominent factors in the acquisition of second homes are escape from stressful city life (Clout, 1972; Chaplin, 1999; Lipkina, 2013) and the need to be in touch with nature (Jackson, 1986). The natural resources, climate and social opportunities of the destination mostly affect individuals' second home preferences (okuyucu and Somoncu, 2016).

The popularity of second homes has increased after the COVID-19 virus emerged in Wuhan, China in December 2019. In this context, studies on the use of second homes during the COVID-19 outbreak are included in the tourism literature. One of these studies was conducted in Çeşme district of Izmir. According to the findings of the study, second home tourism increased significantly in Çeşme during the COVID-19 period. It was determined that this situation caused inflation by increasing housing rents and housing prices. In addition, as a result of the intensive use of second homes, it was determined that the infrastructure was strained and daily life was negatively affected (Türksoy, 2021).

3. RESULT and RECOMMENDATIONS

The proliferation of second homes and the development of second home tourism in Turkey coincided with the enactment of the Tourism Incentive Law in 1982. In this period when mass tourism activities gained momentum, the construction of second homes also accelerated. Initially concentrated in coastal regions, second homes were later built in all regions of Turkey. In this context, the concept of second home tourism emerged. The expenditures made by individuals participating in second home tourism in their second homes provide economic mobility (Marjavaara, 2007). These expenditures revitalize the local economy and create indirect employment (Müller, 1999). Although the development of second home tourism in these regions reduces inter-regional development differences, the use of second homes in certain periods of the year leads to spatial agglomeration by causing the population to increase suddenly. In this context, within the framework of EU harmonization laws, the ability of foreigners to acquire second homes in Turkey has had both positive and negative effects on the economy. This study provides a broad perspective by analyzing the social, economic and environmental impacts of second home tourism. The findings of the literature review and evaluation can be summarized as follows:

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

- Second residences are residences that are located outside the permanent residences of individuals participating in tourism activities and are generally used for vacation purposes. The development of these dwellings usually takes place in areas with high natural and touristic attractiveness.
- Second homes play an important role in economic activities and increase tourism revenues. It also has positive effects such as revitalizing the local economy and reducing unemployment.
- Second-home tourism plays an important role in revitalizing domestic tourism and diversifying the tourism sector. The preference of second homes, especially in the immediate vicinity of big cities, for weekend getaways contributes to the revival of domestic tourism.
- Site selection for the development of second homes is a factor where geographical characteristics are of great importance. Factors such as natural resources, transportation facilities and touristic attractiveness play a decisive role in the location of second homes.
- The effects of second home tourism are studied in various disciplines. Geography and tourism have similar fields of study and there is interaction between these two disciplines.
- In the literature, there are studies on second home tourism mostly designed with quantitative methods. There is a need for more studies that will analyze in-depth with qualitative methods.

As a result of the unplanned development of second home tourism activities, agricultural lands are opened to second home construction, coastal areas are crowded, forests are damaged, unplanned construction, regional inflation and other undesirable consequences (Emekli, 2014). In addition, in these areas, migration from rural areas to cities is accelerating due to increased prosperity due to tourism activities. This situation negatively affects agricultural production (Çıkın et al., 2009; Rye, 2011). Therefore, planning should be done carefully in the areas where second home tourism will be developed. Otherwise, the costs and taxes incurred by local people living in these areas will increase. Therefore, although the positive economic effects of tourism activities are also seen in second home tourism, second homes also cause some negative effects. In this context, the demand for second homes slowed down in the 1990s due to reasons such as the contraction in the construction sector, the principle of prioritizing public interest on the coasts, the increase in the number of accommodation establishments and the cheapening of vacationing, and the 1999 earthquake (Somuncu et al., 2010). However, with the enactment of the law allowing foreigners to acquire property, the demand for second home tourism has started to rise again.

Housing sales to foreigners stimulate both tourism and the construction sector. Both of these sectors employ a large number of people with high multiplier effects. Therefore, they have a positive impact on the economy. The literature emphasizes that second home tourists spend more than other tourists (Okuyucu and Somuncu, 2015). This situation reveals the importance of second home tourism. In order to maximize the benefits of second home tourism, attention should be paid to tourism planning and infrastructure investments in areas where second home tourism is developed (Adamiak et al., 2015; Dal and Baysan, 2007; Müller and Hoogendoorn, 2013).

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

In future researchs, studies can be conducted on the development of planned second home tourism in regions that have not received the required share of tourism investments but are rich in natural resources. In this context, it may be recommended to conduct more qualitative studies in the field of second home tourism and to examine this issue from different perspectives. In addition, more research needs to be conducted on the environmental impacts and sustainability of second homes. These studies can contribute to a better understanding and management of second home tourism. In addition, the effects of second home tourism on local communities in areas where second home tourism has developed can be investigated. These regions could be Istanbul, Ankara, Antalya, Mersin and Antalya, which have the highest number of second home sales to foreigners in Turkey. In addition, the reasons why foreigners acquire second homes in these regions can be inferred from the opinions of second home owners and recommendations can be put forward.

ABSTRACT

In the research process, the use of social and visual semiotic strategies to make sense of events and concepts in the fields of media, mass communication and culture enables the development of new methods. In a semiotic sense, the questioning of codes and ideas in terms of facts and meanings points to the intersection between concepts and semantic content. In this sense, semiotics includes everything that can be understood as signs. It can be said that it is an important tool that shows the development of creative expression as well as the development of technology and media. In particular, media reality has brought different perspectives to semiotic research. Considering the compatibility of graphic design with media and technology, it is normal for different indicators to emerge. For this reason, in this research, both the literature on how semiotic analysis is structured and the semiotic analysis of the posters of the American artist Chip Kidd, who attracted attention with his graphic posters and billboards, were made.

Keywords: Indicator, Semiotics, Graphic Design.

1. INTRODUCTION

Meaning clusters have an extremely complex structure, they represent something different from what they describe, they are filled with new meanings just when we think we understand them, they allow different approaches and even interpretations, they deepen by embracing each other, they embrace people more deeply, they gain meaning again with the existing and developing human culture. In this sense, they need to be reorganized and explained. What fulfills such an effort is the so-called semiotics of signification (Şahin, Arat, 229).

Semiotics is an interdisciplinary field of study that questions the formation of meaning. The meaning can be any text, logo, symbol, photo, building or advertisement. Semiotics, which is a rapidly developing branch of science, especially after the 1960s, has started to be used consciously in the fields of art, communication, marketing and advertising. These are the approaches to reading the representation systems of a text through signs, giving meaning to codes, evaluating intertextual relations with verses, syntax, metaphor and metonymy, and examining the ideology and culture underlying hidden meanings. Semiotics, which emerged from linguistics, has become an independent science with the rapid development of new media and communication technologies in recent years, and has become a universal science with its own unique and interesting microcosms, including linguistics. Beyond natural languages and the meaningful universe that surrounds man; beliefs, customs, actions, passions, advertisements, fashion, architecture, television, cinema, literature, theater, painting and photography are some of the systems consisting of signs, and semiotics aims to reconstruct these expression systems by reading, interpreting and analyzing them. Semiotics develops a model that enables people to make sense of the world they live in (Parsa, Olgundeniz, 2014).

In activities of daily living, real objects or ideas are explained by what individuals perceive and interpret. There are several indications that these objects are covered by the time they are perceived. These metrics may vary depending on the perceived context. The indicators we use for certain purposes in our daily lives and these indicators actually make intuitive-sensory associations (Erişti, 2021).

Astronomy

Semiotics; The terms "semiology" (German) and "semiology" (English) in European languages are based on the ancient Greek word "semeion". The term we call semiotics in Turkish is represented by two different terms in English: "semiotics" and "semiotics". These two terms are synonymous. Both are intended to study signs and meanings. This indicator is for any individual. In other words, it is a matter of creating a status in the mind of the individual that will give him an equal or higher status than himself. A science created by studying the life of indicators in society; This science is social psychology, that is, it will be part of general psychology; this science is called semiotics (Star, Virgo, 2019). The current meaning of the science in question cannot be reduced to the sum of the meanings of the concepts that make up the term Semiotics in Turkish. The merging of two fields of theoretical activity, which correspond to two different terms in Western languages, under a single Turkish term poses such a problem. Semiotics, the first activity to study signs from the perspective of communication, is said to have a realistic approach and approaches language and language skills on a superficial level, as if describing specific, observable physical objects that exist in nature. The second approach, on the other hand, sees language faculties not as a single class object to be observed, but as a whole consisting of constructed and constructed classes of meaning, and tries to reinterpret and understand its basis and formation. In doing so, it is not aimed to become an attitude that is content with describing observable linguistic phenomena, but to create a general theory of linguistic ability and to organize it within a scientific theory (Yasa, 2012).

Semiotics began to become an important approach to cultural research in the late 1960s. Semiotics, based on the work of Roland Barthes, was intended to address in particular any system of signs, regardless of its nature and limitations; pictures, gestures, musical sounds, objects and their complex connotations. Ceremonial, conference, or public entertainment content: they create, if not language, then at least systems of meaning. Saussure's term semiotics is sometimes used to refer to the Saussure tradition, "semiotics", sometimes refers to the Peirce tradition, but today the term semiotics means: the set of signs that includes all kinds of systems within its scope. Semiotics as an academic discipline has not been widely institutionalized. It is a field of study in which many people are involved. It includes different theoretical stances and methodological tools. One of the broadest definitions can be defined as the one made by Umberto Eco, "Semiotics deals with everything that can be taken as a sign" (Chandler, 1994).

Ignoring each other's work, Peirce and Saussure formulated the basic principles of semiotics that underlie modern semiotics. Saussurian semiotics is language-oriented and based on the nature of communication; In the semiotic Peircian approach, the nature of materials is explained in a logical context and from a pragmatic point of view: The main objective is to reveal what we do not know beyond what we know about objects. Modern and post-modern theorists have used the ideas of Peirce and Saussure to understand language and culture. Pondaag explains that semiotics is a science or an analytical method for studying signs. These are the signs that we are trying to find a way between being with people and people in the world. Eco explains

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

semiotics as the study of a set of objects, events, and entire culture in the form of signs. These signs are said to represent something else that has been built on the basis of social contracts. Zaini uses semiotics in the science of communication, especially in the analysis of media messages or texts (Sitanggang, 2020). The use of semiotics in the science of communication is based on the assumption that the medium contains a set of signs. Another scholar, Roland Barthes, was perhaps the first social semiotician to use semiotics to understand media culture in his book *Myths*. In his semiotic analysis, he reveals individual or group interests and ideology regarding social behavior from a political/critical point of view (Erişti, 2021).

The French philosopher Roland Barthes is the most influential figure in the world of semiotics. He was a philosopher, literary critic, structuralist, and semiotician. This semiotician developed the work of Ferdinand de Saussure, including structuralism and semiotics in the text. The key in Barthes' semiotic analysis is the concept of content and content. This model, through Barthes, establishes that the importance of the first stage is the relationship with external reality between the signifier (manifestation) and the signified (content) in a sign. Barthes identifies the most obvious meaning of the indicator as the indicator. By the way, the connotation has a subjective or at least intersubjective meaning. In other words, the signifier is what the signifier tells about an object, while the meaning of the connotation is how it is defined (Siragar, 2022).

According to Barthes, images are linked to aesthetic and ideological elements, paving the way to read and interpret inferences to explain how meaning is created through complex semiotic interaction. Thus, semiotics in media studies provides recipients with the information they need to be able to analyze and create meaningful texts and designs in the future. In this context, Barthes argues that the death of the author/creator of the text allows the recipient to witness the birth of the text and create a form of semiotic production of various meanings, interpretation, reading and observation. It is the complexity of semiotic interpretation and the analysis of messages and media discourses in order to open the semiotician's senses to new methods of using signs in social and cultural contexts. In fact, Roland Barthes' approach is widely applied in media studies, which focus on the semiotic analysis of different media areas such as advertising, cinema, film, music video and cartoon. The influence of Barthes' work in recent years has led communication semiotics and epistemology to question the symbolic interaction of linguistic and non-verbal signs. Barthes has made a great contribution to the field of analysis of textual images in order to reveal their meaning, which is based on the functional order of cultures and systems, and therefore their intermediate importance (Bouzida, 2014).

Figure 1. Barthes' Indicator Analysis

Various concepts are widely used in semiotics. Signs include explicit and implicit meanings that people use in their communication with each other or with entities outside of themselves, such as spoken language, body language, signs, symbols, etc. These symbols are difficult to

TeMALab

 University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

understand and analyze because they contain many different forms. Reference, another concept that shapes this science, is the message that the indicator wants to convey. The sign is defined as a symbolic universe that contains all the signs and associations that the interpreter points to and evokes in his mind. Meaning is the meaning that derives from the relationship between what the signifier wants to represent and what is signified. One of the concepts we often encounter in semiotics is terminology. Anything that has a scientific meaning is called a term. The meanings of terms do not change depending on where they are used. In semiotics, Saussure argues that language is a system because the parts that make up a whole are defined as "systems" (Özdemir, 2020).

Semiotics includes everything that can be considered an indicator. A sign is anything that can be considered a substitute for something else. This other thing does not have to continue to exist as the meaning it represents, anywhere at any time. Therefore, semiotics is a disciplined principle that can examine everything that can be used (Erişti, 2021).

Natural language is a system made up of different behaviors, gestures, images, traffic signs, the spatial layout of the city, musical works, paintings, theatrical performances, films, advertising posters, posters, fashion, literary works, different scientific languages that people use to communicate, in short, the order of passions, the structure of the ways of communication within a nation, an architectural arrangement, a system made up of all the different units of meaning, whether they are for communication purposes or not. The units of these systems, which have different implementation plans, are also generally understood as indicators. In this sense, semiotics; Language, code, properties, etc., are a field of structural chain science. Indicators are actions or structures that refer to something other than themselves. The code is the system by which indicators are organized and defines how indicators can be related to each other. Fiske claims that these indicators and codes have been communicated to others or made available to others. According to Fiske, handing over or receiving signs is a fact of social relations (Özgür, 2006).

Indicator	Indicating	Shown
Traps Banner		Portraits consisting of nested boxes depicted on a rectangular composition and colored writing styles were used. In the design, the use of cold and warm colors together is preferred. At the same time, a remarkable composition has been formed by taking into account the descriptive power of the artist.
Time Poster		The poster named Time, designed by Chip Kidd, draws attention with a design consisting of 100 boxes. In the painting, black, white and red colors are generally used and three colors are concentrated.

September 14-15, 2023, Naples, Italy

Paradise Leaderboard

The poster called Paradise is seen among the remarkable designs of the artist. The poster, which is depicted in a rectangular composition, focuses attention on the styles with the sharpness of the red color, intensifying with the harmony of black and white and its tones.

Indicator

Plain Meaning

The poster consists of nested boxes, and inside each box, there are face faces that attract attention with their perspective feature and color contrasts that provide sharp separation of shapes. Fonts are placed in the upper and lower parts of the poster and integrity is ensured.

Connotation

Although the poster contains concrete things in its plain meaning at first glance, its inner meanings are moving towards abstraction, and the cross-section of each moment attracts attention. The contrast and balance of the colors used are seen as a difference.

The poster shows the times divided into boxes with the tangible and the sections framed by sharp red lines.

The poster is sharpened with frames in which a face is separated by different times and each time.

In a rectangular composition that appears concretely on the poster, there are red text styles in the upper and lower sections and a face face in the middle of the poster.

In the poster, an effective composition arising from the combination of white and red colors on a black background was tried to be created.

2. CONCLUSION and DISCUSSION

Semiotics is an interdisciplinary field of study that questions the formation of meaning. Its meaning can be any text, logo, symbol, image, building, or advertisement. Semiotics, which is a fully developed science, has started to be used consciously in the fields of art, communication,

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

marketing and advertising, especially after the 1960s. These are approaches that aim to read the narrative systems of a text through signifiers, to give meaning to codes, to evaluate the relationships between texts and inscriptions, syntax, metaphor and metonymy, as well as to examine the ideology and culture behind hidden meanings.

ABSTRACT

Urban morphology is a field of study that assists in deciphering these changes by examining the physical form and urban structure of settlements as they evolve over time. The Hamamyolu Bazaar, located in the city center of Eskişehir, has undergone various physical changes over time. These changes have had various impacts on the physical and social structure of the city. In this context, the aim is to conduct a morphological study of the Hamamyolu Bazaar. For the urban morphology analysis of the Hamamyolu Bazaar, a geographical-based morphological analysis method developed by Conzen was employed. In this method, the historical development of the Hamamyolu Bazaar was initially examined. During this step, key turning points in the evolution of the Hamamyolu Bazaar were identified and its historical development was investigated. In the second step, analyses regarding land use parcel-building relationships were conducted using the maps obtained for the identified turning points. According to the results of the study, it was determined that the Hamamyolu Bazaar has undergone changes at the building scale over the years, influenced by various factors such as urban planning and zoning regulations. Additionally, it was revealed that the Hamamyolu Bazaar has been a significant area in terms of recreation and commerce since the establishment of the city.

Keywords: Urban Morphology, Hamamyolu Çarşısı, Eskişehir.

1. INTRODUCTION

In the course of historical development, objects such as buildings, streets, and walls located in urban space undergo various transformations due to various reasons (interventions by users, experts, decision-makers, etc.). From this point, it is possible to assert that space undergoes a "change in state" over the course of historical processes through the activities of individuals. This change in state becomes tangible and observable through spatial transformations within the city, revealing different spatial organizational structures in different periods. Cities can exhibit variations in morphological diversity depending on their size and historical background. Therefore, what is crucial in morphological research is the identification of relationships and differences that occur in various periods (Ünlü, 2018).

Urban morphological studies used to identify the relationships and differences in the transformation of the city across various historical processes have been carried out since the beginning of the 20th century and continue to be examined from different perspectives (Cömert, 2015). In its simplest form, urban morphology can be defined as the examination of the physical form and structure of a city (Santa, 2003). Moudon (1997) expresses that urban morphology is used to read and analyze cities based on their physical forms, and it is employed in determining how cities are constructed and transformed. Madanipour (1996) defines urban morphology as a systematic study concerning the constructed structure of cities, the fundamental forms, plans, structures, and functions of buildings, and how they develop over time. In summary, it is

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

possible to describe urban morphology as a process of changing forms over time. Researchers focusing on urban morphology investigate the development of the city from its establishment to the transformations that occur over the years, identifying these transformations as breakpoints in the city's history (Bayer, 2020). Researchers have employed various methods for urban morphology analyses. Philippe Panerai, Jean Castex, and Jean-Charles Depaule have developed a research model in their works, such as "Elements of Urban Analysis" and "Principles of Urban Analysis," using approaches like the concept and methods of urban analysis, urban structure, urban morphology, and parcel configurations. Within this research model, they have addressed the analysis of urban landscapes through studies focusing on the visual perception dimension (Cullen-Townscape, Kevin Lynch-Urban Image), incorporating it into the analysis of urban form (Bilsel, 2018). Various methods for urban morphology analysis include spatial configuration, morphological analysis using GIS, the Conzen method, the typological-morphological approach, and the connection of urban morphological analyses with the dynamics of cities' social, economic, and political contexts (Hillier and Hanson, 1984; Conzen, 1960; Bayer, 2020).

Conzen method, which is a part of urban morphology within the field of geography, is the most representative work reflecting the concepts and methodological framework of M.R. Conzen's urban morphology approach. The concept of "historical urban geography" that has developed within the field of urban geography shapes the subject matter of urban geography as human settlements, the emergence of cities, settlement patterns, urban systems, and the subjects of historical, social, and economic processes. It has evolved as a subject of study that encompasses the macroform of cities, spatial and functional organization, urban plans, and the shaping and transformations of urban fabric (Bilsel, 2015).

Conzen further developed the concept of morphology, initially used by Schuler in 1898, and approached the morphological development and analysis of cities within the framework of historical development theory (Cömert and Hoşkara, 2018). According to Conzen, urban plans can be analyzed in accordance with their developmental patterns over different time periods. The fundamental unit of analysis is the parcel. The subdivision of parcels provides a systematic infrastructure for urban form. Conzen recognizes that urban plans are composed of different components, which can be observed in variations in streets, parcels, building sizes, and forms (Gürer, 2016).

Conzen focused his research on reading urban landscapes and identified three main features in his studies: urban plan-ground plan, building texture, and land pattern and building usage (Whitehand, 2001). In his analytical method, which he referred to as "urban plan," Conzen distinguishes the three fundamental elements of urban planning: streets, parcels, and buildings (Gürer, 2016). In the historical-geographical morphogenetic method, urban space is analyzed in conjunction with its context. This analysis, known as urban plan analysis, focuses on examining the changes, transformations, and variations that occur in urban space based on the results of changes in parcel, building, and street patterns obtained from historical maps for specific periods, as well as the land use situation in the area (Sakar and Ünlü, 2019; Conzen, 1960).

Conzen conducted his study in Ludlow using the urban plan analysis method, in which he identified all the distinctive areas of the city. To make these identifications, he utilized parcel-building type, land use status, and urban fabric analyses. According to Conzen, the urban fabric,

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

which encompasses not only physical elements but also social experiences, distinctiveness, and historical accumulation, allows for the formation of different development periods and characters over time (Conzen, 1966). Conzen suggests that it is possible to analyze cultural periods and spatial character by analyzing the components of existing conditions, building fabric, and land use. As seen, within the framework of the historical-geographical approach, this study aims to conduct a morphological analysis of Hamamyolu Çarşısı in the context of the changes that have occurred during the historical process.

2. MATERIALS and METHODS

The main material of the study, Hamamyolu Çarşısı, is located in the Odunpazarı region of the city. Within Hamamyolu Çarşısı, you can find traditional bazaars, passages, municipal buildings, residential buildings, hotels, and recreational areas. Hamamyolu Çarşısı serves various functions and is situated in close proximity to the focal points of the city (Figure 1).

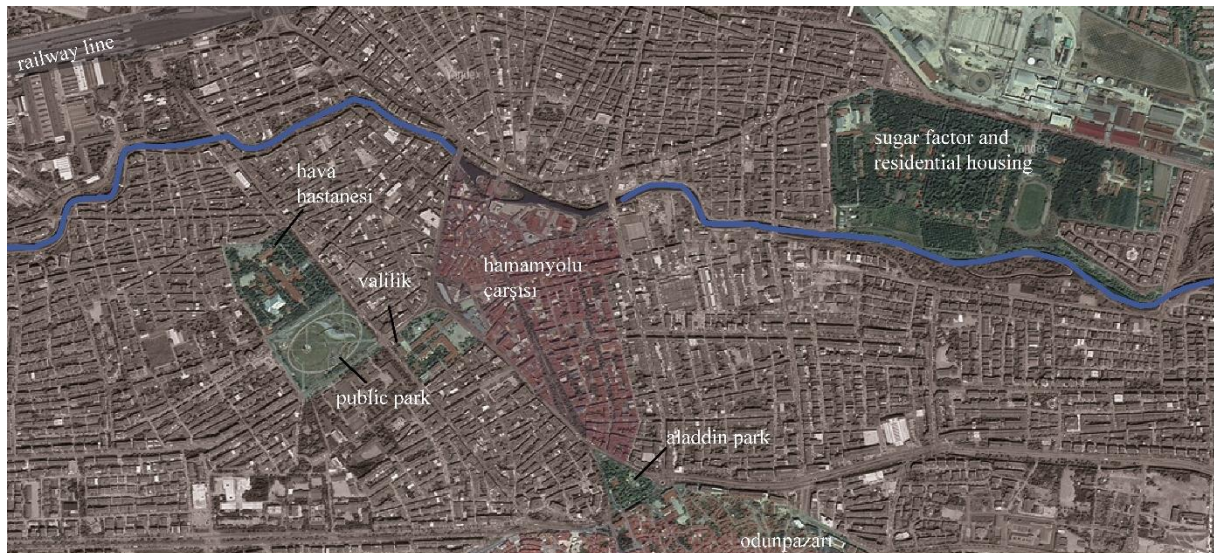

Figure 1. The Location of Hamamyolu Çarşısı within the City

Hamamyolu Çarşısı contains traditional bazaars, the municipal building, passages, residential structures, accommodation facilities, recreational areas, and more (Figure 2). Due to its historical significance and its role as the city's first commercial hub, Hamamyolu Çarşısı holds a prominent place in Eskişehir. It is located in the area bounded by İki Eylül Avenue, Deliklitaş Avenue, and the Porsuk River. Within this area, you can find the city's earliest neighborhoods, namely Arifiye and Deliklitaş neighborhoods. Taşbaşı Çarşısı, located within Hamamyolu Çarşısı, has been designated as an urban conservation area. It is a place where the traditional bazaar culture of the city is preserved. Streets within this bazaar are named after the trades they host. For instance, you can find areas like the Clockmakers' or Goldsmiths' Bazaar. Additionally, the study area serves as a natural hot spring center for the city. The region houses natural hot springs that supply hot water to the surrounding baths. Hot springs have been a significant factor for the city from its history to the present day. The hot spring source is within an area with a diameter of 200-225 meters, situated between the Aerial Hospital and Deliklitaş Avenue. The primary source is collected within the courtyard of the Mosque of the Bazaar (Balta, 2005).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 2. Boundaries of the Study Area

In summary, Hamamyolu Çarşısı has been selected as the primary material for the study due to its significance in tracing urban memory over a vast historical period, its role in maintaining vibrant and continuous public life, and its appeal to a diverse range of users. The study focuses on Hamamyolu Çarşısı, which encompasses various places such as the Sıcak Sular Bölgesi, Taşbaşı Çarşısı, Hamamyolu Caddesi, and Çukur Çarşı. Therefore, there are studies that specifically address Hamamyolu Çarşısı and the spaces within it. Looking at these studies: Aksoylu (1995) collected data on the condition of Taşbaşı Çarşısı before and after expropriation, and provided design recommendations for this historical area. Albek (1991) and Ertin (1994) discussed the historical and physical development of Eskişehir. Alpan (2016) highlighted the role of Hamamyolu Caddesi as a central axis and offered design recommendations to address the issues that emerged in Hamamyolu Caddesi during the 2010s. The study 'Dünden Bugüne Eskişehir'deki 14 İşletmenin Öyküsü,' edited by Kozak (2013), examines the oral history (in-depth interviews) and the historical development of unique flavors in Eskişehir, especially in Hamamyolu Çarşısı. Nalçakan et al. (2015) evaluated changes in Çukur Çarşı within the context of the concept of 'place.' Üstün and Özkan (2016) focused on the spatial transformations of Hamamyolu Caddesi since the Republic Era. Büyüktaş and Kaçar (2023) delved into the impact of the furniture in Hamamyolu Caddesi and other parks within the city on the city's identity. Upon examining these studies, it becomes evident that the absence of a morphological analysis of Hamamyolu Çarşı and its constituent spaces underscores the importance of the study in the existing literature.

Analysis of the Morphological of Hamamyolu Çarşısı

To conduct the morphological analysis of Hamamyolu Çarşısı, the study was carried out in two distinct phases. In the first phase, the historical development of Hamamyolu Çarşısı was

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

examined using data obtained from newspaper articles, works in the Eskişehir City Memory Museum, exhibitions, literature, and traveler's observations. This allowed for the identification of critical turning points in the history of Hamamyolu Çarşısı. In the second phase, the morphological analysis of Hamamyolu Çarşısı was performed by comparing maps related to the area, including street layout, block-parcel relationships, and building-parcel relationships. Conzen defines urban morphology as the acquisition of layers of historical periods. With this method, changes and transformations in land use, building fabric, and genetic planning units are analyzed (Cömert, 2015). The Conzen method is grounded in a historical-geographical approach, making it suitable for this study. The maps used in the Conzen analysis were selected to be from years corresponding to the significant turning points in Hamamyolu Çarşısı. Various maps from different years and characteristics, aerial photographs, newspaper photographs, and archive photographs were utilized in the morphological analysis of the study area. The maps used in the study date back to the 13th century, 1891, and 1956.

The historical development of Hamamyolu Çarşısı:

Cities undergo various social, physical, political, and economic processes that shape their forms. Streets, buildings, and other physical components adapt to changes in spatial practices by users and shifts in the cultural geography within the city over time. Therefore, it can be said that historical processes are significant variables that influence the physical forms of cities. Historic city centers, with their accumulated historical layers, are noteworthy areas within cities for their historicity, layering, and urban characters (Sakar and Ünlü, 2019). In this context, in order to assess Hamamyolu Çarşısı morphologically, it is essential to first determine the changes it has undergone during its historical development, how it has evolved, and identify the key turning points throughout its historical timeline. To achieve this, data was collected from local (Milli İrade, Sakarya, İstikbal) and national (Akşam, Cumhuriyet, etc.) newspapers, existing studies in the literature, the Eskişehir City Memory Museum, and the Cultural Heritage Preservation Board. The assessment of Hamamyolu Çarşısı's morphological changes and historical evolution is crucial for understanding its role in Eskişehir's urban development and the preservation of its cultural heritage.

Hamamyolu Çarşısı has played a central role within the city, and its historical fabric is rich and diverse. In the Byzantine era, it was utilized for recreation and as a market due to its natural hot springs (Doğru, 2005). Travelers who visited the city in the 1800s mentioned the existence of hammams and markets in this area (Acar, 2009). During the Seljuk period, baths were constructed because of the presence of hot springs, contributing to the city's economy and social life. The Erler Hamam, which still stands today in Hamamyolu Çarşısı, serves as an example of the hammams constructed during the Seljuk era (Doğru, 2005 and Altınsapan, 2009). The city, upon falling under Ottoman rule, experienced a period of stagnation. During the Ottoman period, several hammams were constructed in the city, such as the Şengül, Alçık, Kıymet (known today as Has Hamam), and Yenice (known today as Vakıflar Hamamı) hammams (Koşlu and Birgün, 2015; Acar, 2009). Hamamyolu Çarşısı, during the Ottoman era, was one of two main areas within the city (the other being the residential area known as Odunpazarı). This area was referred to as the market district where a marketplace was established, and soldiers used it as a rest area (Doğru, 2005). As observed from the city's foundation until the Ottoman period, it served various functions, including recreation, markets, shopping, and more. The character of Hamamyolu Çarşısı began to change in 1877 with the arrival of immigrants and the opening of the Baghdad Railway, marking the beginning of a transformation in the area.

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

In 1877, Rumelian immigrants began to settle across the Porsuk River. These immigrants made positive contributions to animal husbandry and agriculture in the city. As a result, a weekly market established in the area was transformed into a fair that operated for 15 days under the order of the sultan (Kozak, 2013 and Albek, 1991). The influx of immigrants led to the formation of new neighborhoods within Hamamyolu Çarşısı. The Arifiye neighborhood, known today as Arifiye Mahallesi, is an example of the initial neighborhoods that emerged within Hamamyolu Çarşısı during this period. During this time, various types of buildings with different functions were constructed within Hamamyolu Çarşısı. The Pirinç İş Hanı, Ottoman Bank (now Garanti Bank), Taş Han, and the fountains built for using the hot springs are examples of such structures.

Table 1. Buildings Constructed in the Late 19th Century

Taş Han (EKVKK, 2021)

Osmanlı Bankası - Present-Day Garanti Bank (EKVKK, 2022)

Fountains (Atuk, 2021)

The presence of the railroad and immigrants led to social changes in Hamamyolu Çarşı, resulting in spatial diversity. The presence of immigrant communities' nightlife influenced the city's way of life, leading to changes on a spatial scale. As an example of this, in the Çukur Çarşı area, there were not only coffeehouses but also taverns. It is worth noting that during this period, this location became home to one of the first taverns established by a Muslim in Anatolia (City Memory Museum, based on the oral history account by Kemal Yakut, 2022a). The presence of a tavern suggests the possibility of alcoholic beverage production in the city. During this period, the region of the hot springs housed Anatolia's first alcohol distillery (Sakarya Newspaper, 1982a).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 3. News about the alcohol factory opened in the 1800s (Sakarya Newspaper, 1982a)

In 1908, the city's first local newspaper, Nimet Newspaper, was published, and the newspaper's printing press was established on Taşbaşı Caddesi (Yakut, 2007). This information is also found in the Hakimiyet Newspaper;

"Zeytunzade Sadık Efendi brought a journalist named Mehmet Burhanettin to Eskişehir. He covered all the expenses and, in 1908, opened Nimet Newspaper. It was located at Taşbaşı, Number: 10" (quoted from Yakut, 2007).

In 1915, the Ottoman Agricultural Store was opened in Hamamyolu Çarşısı. The store's opening was reported in the Eskişehir Newspaper;

"Since the day our store opened, we have fulfilled our duty of gratitude for the favor and support we have received from our esteemed customers. It is especially requested from our dear customers, in their own interest, that they do not visit other shops once they come to our store for whatever they need. Eskişehir: Bonmarche in the Lower Market," (quoted from Yakut, 2007).

At that time, municipal activities were also observed in the market area. Various activities such as the repair of the Roman (Stone) Bridge, the opening of shops around the bridge, and the supply of clean water to the market area are mentioned. These activities were reported in Eskişehir and Hakimiyet newspapers;

"The wooden part of the market bridge deteriorated over time, leading to its reconstruction using iron pipes and the decision to build shops, cafés, and similar structures on both sides," (Eskişehir Newspaper, 1910; quoted from Yakut, 2007).

"Through a motor-driven distribution system, the municipal office delivers hot water to the residents, especially those in the lower and partly upper neighborhoods, and their efforts in ensuring the needs are truly admirable and superior," (Hakikat Newspaper, 1911; quoted from Yakut, 2007).

This part mentions the opening of the first pharmacy in the city, Ömer Lütfü Pharmacy, near the Roman Bridge, offering both medicine sales and medical treatment services. Details regarding this can be found in the Metanet Newspaper;

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

"Ömer Lütfü Eczanesi (Pharmacy). Dr. İstevraki Papayatoplu at Köprübaşı, Eskişehir. Specialist in internal medicine, surgery, and women's diseases. Dr. İstevraki conducts examinations daily. This announcement is made to the esteemed public." (From Metanet, 1912, as cited in Batur and Özdemir, 2018).

During this period, various buildings were constructed within Hamamyolu Çarşısı, increasing spatial diversity. The development of the street was met with destruction in 1922 due to the damage inflicted by Greek soldiers, who set fire to the shops and stores in the bazaar area.

Figure 4. Hamamyolu Çarşısı After the Greek Occupation (Acar, 2009)

The damage caused to the city by the Greeks was reported in the Hakimiyet Newspaper:

"The guides of Western civilization, in a span of twenty-four hours, turned a city that would have had the most prosperous and promising future in Anatolia into ruins. We could not have foreseen that fire and flames would destroy it in all twenty-four aspects." as depicted in the image, the extent of the damage caused by the Greeks illustrates the magnitude of the destruction (Yakut, 2015). It is evident that the damage inflicted by the Greeks served as a turning point for Hamamyolu Çarşısı. In the early years of the Republic, the city attempted to recover from the inflicted damage while striving to keep up with the developments across the city. Following the liberation from the Greek occupation, the city sought to alleviate the economic and social repercussions of the damage incurred. Temporary permits were granted for new barracks constructed in the market area after it was burned by the Greeks. Cobblestone pavements were installed in the market district, and Yediler Park and Yediler Bridge were built (Ertin, 1994, and Güneş and Yakut, 2007). Information regarding the opening of Yediler Park and its heavy use during that period can be found in Vakit Newspaper:

"... Yediler Park, located in the heart of the city, was opened... The park saw some improvements this year. Last year, a large pool was built. This year, we see that park walls have been constructed, and the shapes of garden fences have changed. The park's radio plays from 17:00 to 22:30. At night, there are many people who come to the park to listen to the radio and take walks..."

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 5. Yediler Park (Atuk, 2021)

During this period when hot springs were used, it can be observed that hot water was used both in public baths and in homes (Albek, 1994, Güneş and Yakut, 2007, and Eskişehir Halkevi Magazine, 1933). In the market area, you could find Erler (Men's), Asker (Kıymet) Bath, Şengilcık, Alçık, Yenice, Asri, and Şifa Bath. During this time, it was decided to reconstruct the Yenice Bath as it couldn't meet the requirements. The bath project, designed by the foreign architect of the time, Professor Deps, was initially proposed for implementation. However, it was considered unsuitable for Turkish customs and was later modified and carried out by Turkish architects (Özaktaş and Arsev, 1943). In 1923, a contract was awarded to prepare a map of the city as of that day. In 1924, the city's first urban plan was developed, dividing the city into different zones and planning its streets and roads based on the examples of European cities. This urban plan was partially implemented until 1936 (Planning Eskişehir in the 1930s, 2021).

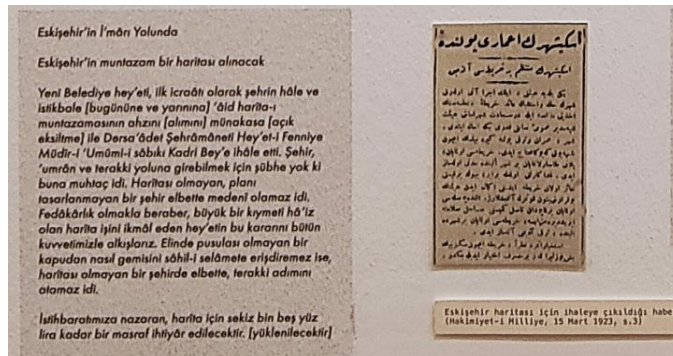

Figure 6. Announcement for the Tender of the City Map (Source: Planning Eskişehir in the 1930s, 2021)

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 7. News of Approval for the City Map (Source: Planning Eskişehir in the 1930s, 2021)

In the zoning plan, changes can be observed in Köprübaşı, Taşbaşı Çarşısı, and İki Eylül Caddesi. In this zoning plan, some of the shops in Köprübaşı and Taşbaşı Çarşısı were allocated for road and pavement. However, due to financial constraints and resistance from the shopkeepers in the bazaar area, this zoning plan was not fully implemented. In the 1930s, this resistance was put to an end, and more than 300 shanties (temporary licensed shanties) in the bazaar area were demolished, and new brick shops were constructed in line with the city plan (Yakut, 2015 and Vakit, 1933). This situation is reported in the Akşam Newspaper:

"...an order has been issued for the demolition of more than 300 shacks within 48 hours. Now the shacks are being demolished, and preparations are being made for new construction. The city has had a regular plan dating back to 1924. Due to financial constraints, the municipality could only gradually implement this plan during construction. The demolition of the shacks will enable the implementation of a significant portion of this plan, leading to the opening of new streets and the expansion of narrow ones..." (Akşam, 1933).

The transformation on İki Eylül Avenue is as shown in Figure 8.

Figure 8. İki Eylül Avenue opened between 1924-1938 (Source: Planning Eskişehir in the 1930s, 2021)

This situation also indicates the influence of foreign architects and urban planners in the city. An example of this influence is the urban planning proposals made by the French urban planner H. Lambert in 1938-1939. News about Lambert preparing an urban plan for the city was reported in newspapers.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 9. The Eskişehir Plan Prepared by Lambert (Source: Planning Eskişehir in the 1930s, 2021)

The ongoing urban development activities led to the expansion of residential areas in the regions previously used as vegetable and fruit orchards. One of these neighborhoods is Arifiye Mahallesi located within Hamamyolu Çarşısı. In addition to residential structures, it can be observed that various buildings with different functions such as industrial facilities, cinemas, mosques, hotels, and restaurants were constructed within Hamamyolu Çarşısı during this period. This spatial diversity was depicted in the Akşam Newspaper with the headline "Eskişehir's landscape has changed.";

"...Construction is on the rise in the city, with new and large buildings going up everywhere. ... Wherever you go, you can see that several buildings are under construction... It seems like there are almost no empty plots left in the city center... The new buildings have altered the city's landscape... Eskişehir's streets are becoming more orderly..." (Akşam Newspaper, 1933).

During this period, Hamamyolu Çarşısı began to flourish as various structures were added, and it started to recover from the damages it had suffered. In this era, we can observe the construction of a mosque and accommodation buildings in Hamamyolu Çarşısı. The Çarşı Cami, Ziraat Bankası, Eskişehir Bankası, Köprü Palas Otel, Çağlayan Palas Oteli, Porsuk Oteli, Yasin Çakır Un Fabrikası, and the office building for the Yasin Çakır Un Factory were among the structures built during this period. While the Çarşı Cami, Ziraat Bankası, and the factory's office building (known as the İstanbul Oteli) still exist in Hamamyolu Çarşısı today, Köprü Palas Otel, Çağlayan Otel, Eskişehir Bankası, and the Yasin Çakır Un Fabrikası are no longer located in the area. The Yasin Çakır Un Fabrikası had mills along the banks of the Porsuk River, and thanks to these mills and dams, it was possible to take boat rides on the Porsuk River with ease (Akşam, 1934a). The opening of official institutions, banks, and the presence of the market in this area, among other factors, made Hamamyolu Çarşısı a focal point in people's daily lives. Additionally, with the opening of cinemas, restaurants, and other similar establishments, it became one of the most visited areas in the city. The opening of cinemas during this period, as reported in national newspapers of that time, is indicative of the lively social life taking place in the Çarşı district. Cinemas operated in Hamamyolu Çarşısı between the years 1926 and 1990. Some cinemas in the area also had gardens overlooking the Porsuk River. National newspapers

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

provided information about these cinemas and their gardens, highlighting that the gardens served as meeting places (Akşam, 1934b).

"...Park Cinema's garden is also the second meeting point for Friday gatherings... This garden is bigger and more beautiful than Porsuk Hotel's garden... Here, there's a beautiful and crowded musical group. Most of the customers are the city's youth..." (Akşam, 1934b).

"...Modern and extensive neighborhoods have been established around Porsuk Creek, and buildings are rising. Köprübaşı has changed completely; old buildings have been demolished and replaced with large and tall concrete structures. To express how advanced the city has become, it's enough to say that it has five cinemas that could outshine Istanbul..." (Kurun, 1938).

In the 1960s and subsequent periods, various activities took place in Hamamyolu Çarşı. A casino building was constructed in the garden of the Porsuk Hotel.

"...In a short time, our city is at risk of losing its green spaces. Various parks and green areas have been replaced by buildings, leading to the disappearance of these parks... There is a plan to construct a hall and a casino in the part of the Municipal Park located by the Porsuk River. We expect that relevant authorities will prevent this situation and take into account the public's need for green spaces..." (Sakarya, 1963a).

These expressions highlight that the construction of casino buildings was not positively received due to the decrease in green spaces. The removal and damage to plants and pine trees within the garden during the construction are mentioned (Sakarya, 1963b). Another arrangement involved the reformation of Çukur Çarşı.

Figure 10. Çukur Çarşı (Source: Sakarya, 1982 ve Atuk, 2021)

Another change that occurred in the 1960s was in Yediler Park. The riverbed of the Akar Stream, which merges with Hamamyolu Avenue, was altered, and Sebahattin Günday Park was established.

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Figure 11. Yediler Park Transformed into a Park in the 1960s (Source: Atuk, 2022)

As a result of the park's arrangement, the newspapers of the time reported:

"... In the meantime, especially the new Yediler Park has attracted great interest from the public. In the evenings, it is impossible to find a place in the park, which is particularly favored by housewives. In the meantime, the municipality has made the fountain placed on the Akar Stream more colorful..." (Sakarya, 1967).

In the 1980s, Hamamyolu Avenue underwent changes due to the pollution of the stream that flowed along it. The local newspapers reported the pollution of the stream:

"... The Akar Stream, which passes through Sebahattin Günday Park (Yediler Park), the only sitting and children's play area in our city, has become quite dirty, spreading bad odors in the surrounding area due to complaints... (Milli İrade, 1987b).

"... Once upon a time, the Akar Stream used to flow sparkling clean and pure along the edge of Hamamyolu. In recent days, due to the careless disposal of garbage by the public and the authorities' lack of interest, it has turned into a pile of trash and filth..." (Sakarya, 1991a).

"... Due to this indifference, this beauty has almost disappeared, clean air has vanished, the waters have receded, and the riverbed has been filled with garbage residues as people have raced to do so... statues have been left alone with the trash..." (Sakarya, 1991b).

In the 1990s, the stream passing through Hamamyolu and Savtekin Streets, which flowed into the Porsuk River, was covered. Within the scope of the Hamamyolu Project, the goal was to cover the stream and replace it with three ornamental fountains adorned with fountains. As part of this project, the Emek Cafe, which had been in operation in the same location in Yediler Park for 29 years, was demolished. In addition to Emek Cafe, the bridges that had become symbolic of the stream were also demolished (Milli İrade, 1992a). The project aimed to transform the street into a green boulevard with cobblestone paving (İstikbal, 1993 and Milli İrade, 1992b and Sakarya, 1991c and Sakarya, 1992 and Sakarya, 1993a and Sakarya, 1993b). The new

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

appearance of the street as a result of the Hamamyolu Project was described in local newspapers as follows:

"Only 10 years ago, the stream that added beauty to the city's appearance has now become history. The stream that once added beauty to the Yediler, Hamamyolu, and Sıcak Sular neighborhoods was cleaned, rehabilitated, and ultimately closed, effectively erased... The place where the stream, which used to nourish the willow trees and bring color with its cascades to Günday Park, once flowed, is now an empty space." (Milli İrade, 1992a).

"Hamamyolu residents, now free from the garbage-filled stream, wear smiles on their faces. Hamamyolu, considered as the only street worth showing in Eskişehir, is praised for its created fountains, the arrangements made, and the myriad beautiful flowers, and various types of trees that adorn it, making Hamamyolu a different kind of celebration now..." (Sakarya, 1993c).

In the 1980s, due to the inadequacy of the Porsuk Hotel building to meet the municipality's needs when it was used as the municipal building, a decision was made to construct a new municipal building (Sakarya, 1982c). Initially, the Çukur Çarşı area was considered suitable for the construction of this municipal building. However, this location was abandoned due to concerns about the stability of the ground (Sakarya, 1983). Subsequently, it was decided to build the municipal building on İki Eylül Caddesi, across from the Vilayet Building. During the period when the Municipal Building was constructed, the following statement described the structure:

"The ongoing construction of the new municipal palace, covering an area of 8390 square meters, was expected to surpass the Vilayet Building in terms of architectural significance upon its completion." (Milli İrade, 1987a).

As the 1990s approached, there was a renewed effort to rehabilitate the Çukur Çarşı area. In 1998 and the 2000s, Çukur Çarşı was demolished twice and is now as depicted in Figure 12.

Figure 12. Çukur Çarşı in 1998 and the 2000s. (Source: EKVKK, 2002 ve URL 1)

In the present day, an important development on Hamamyolu Street is associated with the Hamamyolu Park and Square Renovation Project, which was implemented in 2018 under the name "Hamamyolu Urban Deck" by Yazgan Architecture (URL 2). The construction process and the subsequent period were covered in newspapers. Regarding the new appearance of the street, newspapers featured the following expressions:

"Hamamyolu Street: Eskişehir's New Attraction Center... Hamamyolu, which the residents have already embraced, now features children playing games in specially designed play areas. Children seem to particularly enjoy the trampolines." (URL 3).

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

"Intense Interest in Hamamyolu Street... Hamamyolu Street, with its new look, continues to attract significant attention from the public. Cafes serving teas, coffees, and Turkish coffee from various countries offer a wide range of options, from sandwiches to ice cream." (URL 4).

Under this heading, an attempt has been made to identify the historical turning points of Hamamyolu Çarşısı (Hamamyolu Bazaar) and its characteristics in the eyes of urban residents. The timeline for Hamamyolu Çarşısı is outlined as follows: Pre-Baghdad-Berlin Railway Era (Pre-19th Century Hamamyolu); The Arrival of Immigrants and Railway Construction (1894-1920); Hamamyolu in the Early Years of the Republic (1920-1960); Expropriation of the Sıcak Sular Bölgesi and Transformation of Yediler Parkı (1960-1980); Expropriation of Taşbaşı Çarşısı and the Hamamyolu Project (1980-2000); Demolition of Çukur Çarşı and the Commencement of Tramway Usage (2000-2010); Hamamyolu Park and Square Renovation Project on Hamamyolu Caddesi (2010 and the Present): This marks the latest development, which is the Hamamyolu Park and Square Renovation Project on Hamamyolu Caddesi. Throughout these stages, Hamamyolu Çarşısı is described as a place located in the city center, serving as a breathing space for urban residents, with a vibrant public life, and functioning as a recreational, commercial, and more space. This description is drawn from national and local media, travel narratives, and literature sources, illustrating its historical and contemporary significance in the urban context.

Figure 15. Structures Built between 1900 and 1950 (Source: Odunpazarı Municipality, 2022, and YandexMap)

a. The Spatial Analysis of Hamamyolu Çarşısı Using the Conzen Technique:

Conzen suggests that the morphological changes in a city can be tracked through urban landscape elements. For a morphological analysis, he considered the urban landscape elements

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

to be street patterns, the relationship between filled and empty spaces, building block-parcel relationships, building-parcel relationships, and land use characteristics. Among these elements, he noted that street patterns are the most resistant to change, as they are defined as the boundaries of public spaces. In contrast, parcels and buildings undergo faster changes due to their connections with private property relationships (Şahin and Saban, 2020). The examination of urban planning reveals that the complex of the three elements defined as streets, parcels, and buildings in the urban area results in individualized combinations in different areas of the city. Each combination gains uniqueness due to location conditions, providing morphological homogeneity or unity in some or all aspects of the area. Urban plans continue to exist, develop, and function within the physical and human context. Therefore, plan analysis should encompass an evaluation of not only the physical conditions but also the economic and social development of the city (Conzen, 1960). Based on this, a spatial analysis of Hamamyolu Çarşısı will be conducted using Conzen's method, focusing on plans.

Figure 13. Land Use in Hamamyolu Çarşısı Over the Years (Source: Tanyeli, 1987; Koylu and Birgün, 2015, Odunpazarı Municipality, 2022)

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

When examining the maps from the 13th century, 1891, and 1956, it is evident that changes occurred in Hamamyolu Çarşısı on a building and parcel basis. In the 13th century, the Taşbaşı Çarşısı and the Sıcak Sular Bölgesi could be discerned on an island-parcel basis. In the 19th century, island-parcels expanded to cover a larger area, featuring garden usage. In the 20th century, the Taşbaşı Çarşısı and the Sıcak Sular Bölgesi displayed similarities. However, when compared to the 19th-century map, the Hamamyolu Çarşısı, with more distinct boundaries on an island-parcel basis, emerged. These differences can be attributed to various factors from that era, such as fires, the opening of different streets, and the condominium ownership law.

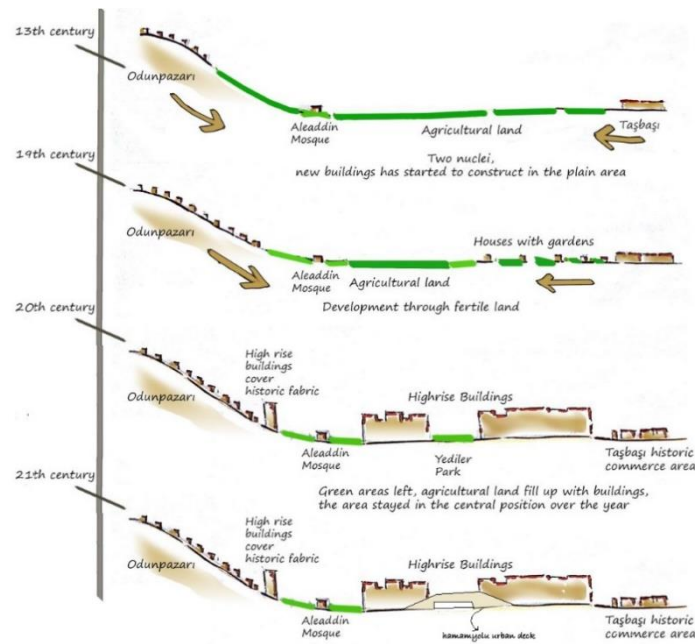

Figure 14. Schematic Representation of the Historical Development of Hamamyolu Çarşısı
(Adapted from Hakyemez, 2016, by the author for this study)

In the 13th century, it is observed that the area now known as the Sıcak Sular region, which was initially used for Taşbaşı Çarşısı, had some vacant plots around the Akar Dere. By the year 1891, due to the migration of people and the construction of the railway, there were notable differences in terms of spatial and land use. During this period, various markets were established in Hamamyolu Çarşısı, various spaces were constructed, and the area known today as Deliklitaş was used for farming and gardening. In the region known as Arifiye Mahallesi, residential and commercial areas were used alongside gardens. By 1956, it can be seen that the boundaries of Taşbaşı Çarşısı, including the Sıcak Sular Bölgesi, and Arifiye Mahallesi were being defined on an island-parcel basis, with recreational areas being utilized (Yediler Parkı). Even during this period, Deliklitaş Mahallesi had occasional residential settlements, but it was primarily used for gardening and farming (Figure 14).

Figure 15. Filled-Empty Analysis Over Different Years (Koylu and Birgün, 2015, Odunpazarı Municipality, 2022)

When examining the filled-empty analysis between 1891 and 1956, it is possible to see that within the emerging island-parcel boundaries (especially in Deliklitaş Mahallesi), there were occasional buildings, and Hamamyolu Caddesi was being used as a recreational area. Data obtained from newspaper articles and the Conzen analysis suggest that Hamamyolu Çarşısı has been an important space for the city in terms of commerce, recreation, and social aspects throughout its history, from the past to the present.

3. CONCLUSION and RECOMMENDATIONS

Urban morphology, in its broadest sense, helps us understand how a region within a city has undergone changes from the past to the present. In this study, the concept of urban morphology was used to identify the transformations and breakpoints that Hamamyolu Çarşısı has experienced from the past to the present. To achieve this goal, an attempt was made to identify the breakpoints of the market from newspaper articles. Based on the results obtained, the following periods were determined: Before the Baghdad-Berlin Railway (pre-19th century Hamamyolu); Arrival of Immigrants and Construction of the Railway (1894-1920); Early Years of the Republic in Hamamyolu (1920-1960); Expropriation of the Sıcak Sular Bölgesi and Transformation of Yediler Parkı (1960-1980); Expropriation of Taşbaşı Çarşısı and the Hamamyolu Project (1980-2000); Demolition of Çukur Çarşı and Commencement of Tramway Use (2000-2010); Hamamyolu Park and Square Arrangement Project on Hamamyolu Caddesi (2010 and the present). These breakpoints resulted from various factors, such as fires, the opening of different streets, and condominium ownership laws. The use of 'recreation' on the street, which has witnessed transitions from single-story buildings to multi-story buildings and from garden usage to residential-commercial use, has remained unchanged from the past to the present. Hamamyolu Çarşısı, which constitutes the first commercial nucleus of Eskişehir,

consists of baths, business buildings, passages, row shops comprising adjacent shops, banks, mosques, cinemas, residences above the shops, trees on the street, and, although it is closed today, a water element passing through it and green park areas. When examined through the concept of urban morphology, it is evident that Hamamyolu Çarşısı has a rich historical process.

Thanks and Information Note

The data used in this study, including newspaper articles, plans, etc., were obtained and developed from the author's master's thesis titled 'Reading Changing Urban Memory Elements Through Shopping Spaces: The Case of Hamamyolu Çarşısı,' which the author completed in 2022.

ABSTRACT

Natural disasters such as earthquakes and fires trigger the need for urgent housing, therefore, rapid manufacturing technologies are being developed. With the use of 3d printing (3DP) technology, structures can be built in more economical and faster ways. However, the measures should be taken in terms of energy efficiency and environmental impact due to the use of cement-based materials with high initial embodied energy. The most common contemporary building materials are autoclaved aerated concrete (AAC) and brick in Turkey. Therefore, it is aimed to compare the energy consumption and global warming potential of AAC, brick and 3d printed concrete (3DPC) in this study. These materials have the same wall thicknesses with different thermal conductivity (U) values in accordance with TS 825, national thermal insulation rules. The system boundary covers the production (A1-A3) and use (B6) stages. Because of being the third most populated province of Türkiye and the location in the first-degree seismic zone, Izmir was selected as the study area. Design Builder software was used to calculate the operational energy and carbon values; and environmental product declarations (EPDs) were used for the production stage. According to the results, the total energy consumption increases in the 3DPC by 20.4% and 17.7% compared to AAC and brick alternatives, respectively. On the other hand, using foam concrete in 3d printing may assist to reduce operational energy and carbon values up to 9.6% .

Keywords: 3D Printed Concrete, 3D Printed Foam Concrete, Building Materials, Energy Consumption, Carbon Emission.

1. INTRODUCTION

While the world is struggling with the climate crisis, it also has to deal with natural disasters. Due to earthquakes and fires that affect masses of people, many of them can suddenly become homeless and have difficulty meeting their basic needs. In such emergencies, there is a need for durable structures to be built with rapid manufacturing technologies. Since the extent of the disaster and the duration of the victimization are unknown, sheltered structures should be built to be minimally affected by external environmental conditions. On the other hand, considering global warming and resource depletion, the energy consumption of these structures should be reinterpreted and evaluated within the framework of a sustainable approach.

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

3d printing (3DP) technology has the potential to be used in emergency housing construction thanks to its advantages such as fast installation, sustainability, and affordability (Markin et al. 2021; El-Sayegh et al. 2020). Compared to traditional construction methods, the 3DP technique offers an efficient, economical, and reliable solution (Ahmed, 2023). Besides its ability to minimize material waste by reducing material costs, 3DP can reduce 50-80% of the total cost of the project in terms of labor. This reduces the number of project employees required, minimizes occupational accidents and injuries, and reduces the cost due to human failures. Thus, the total project cost can be reduced by 35-60%. The 3DP method greatly shortens the construction time, with a 25% reduction compared to a house built with traditional methods (Craveiro et al., 2020; Shomberg, 2016). One of the fundamental reasons for the decline in worker productivity is the failure to integrate new technologies such as 3D printed concrete (3DPC), also known as additive manufacturing (El-Sayegh et al. 2020). This technology has the potential to transform construction processes by gaining an important place in the building industry.

Foam concrete is a cementitious material with a low self-weight. Its light weight is due to the addition of air to the matrix of a suitable foam formed with cement paste. It is preferred in the construction industry due to its advantages over normal concrete such as low self-weight (Wei et al., 2013), thermal insulation (Amran et al., 2015), acoustic absorption (Tada, 1986), fire resistance (Valore, 1954) and workability (Chica & Alzate, 2019). However, ultra-low-density foam concretes may have low mechanical strengths and potential instability issues (Jones et al., 2016; Jones et al., 2017). Mechanical properties depend on dry density as well as foaming agent, curing condition, cement type, and water/cement and air/cement ratios. A new type of 3DP technique involving lightweight foam concrete (3DP-LWFC) offers several advantages such as the ability to maintain dimensional stability in the fresh state, architectural flexibility, and material savings owing to the automated extrusion production process (Falliano et al., 2020). This material stands out as a potential solution in the construction industry by providing energy savings and environmental advantages. 3DP-LWFC contributes to energy efficiency with its high insulation performance saving construction cost and time (Markin and Mechtcherine, 2021).

Among studies on 3D printing, which has been utilized in bridges, residences, offices, and emergency shelters, the number of those specifically addressing energy efficiency (Suntharalingam et al. 2021; Alkhalidi and Hatuqay, 2020; Pessoa et al. 2021) and environmental impacts (Shuaib et al. 2021; Khosravani and Reinicke, 2020) has recently increased. Some of the studies suggest that the use of 3DPC with only air cavities is not sufficient in terms of thermal performance. Suntharalingam et al. (2021), found that the cavities do not satisfy the U value according to standards. The lowest U value was achieved as 0.34 W/m²K with the help of insulation. In another study, Alkhalidi and Hatuqay (2020) achieved to design a wall with a U value of 0.15 W/m²K. They designed a double-row, insulation-filled wall made of 100% silica sand, and the thickness of the wall is 0.5 m.

The aim of this study is to quantify the energy performance and carbon emission of 3DPC and 3DP-LWFC in the most energy intensive life cycle phases, A1-A3 (production) and B6 (use), in construction industry and to compare them with contemporary building materials in Izmir climate conditions.

2. MATERIALS and METHODS

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Izmir, which is located in the 1st degree earthquake zone is the third most densely populated province of the country, was selected as the case area for the study. Dikili, which is affiliated to this province, is among the regions whose population increases with the influx of tourists in summer. A hypothetical house with a floor area of 100 m² and belonging to a family of 4 people was chosen as the subject of the study. The plan diagram and the 3D model produced in Design Builder are shown in Figure 1.

Figure 1. Plan scheme of the case study house (left), 3d model (right)

The energy consumption and related carbon emissions of this house, which was produced with autoclaved aerated concrete (AAC), brick, 3D printed concrete (3DPC), and 3DP-LWFC wall alternatives, were examined within the scope of the pre-occupancy and occupancy phases of the building. The climate data of the relevant region used in Design Builder, an energy simulation program, was taken from Url-1. While designing the openings of the house, the window-to-wall ratio (WWR) on all facades was set to 20%. The indoor temperature in the simulation environment is 21°C in summer and winter, set points were 27°C and 15°C for summer and winter, respectively. Heating is active between October-March while cooling is between June-September, from 07:00 am to 23:00 pm.

When designing the wall components, the wall thicknesses were kept constant, the standard dimensions of the main building material were selected for the exterior and interior walls, and the thickness of insulation layers of the facade were determined. 3DPC was used in three layers and the gaps were filled with insulation material since it has a thin layer and does not meet the standard thermal conductivity value by itself. The properties of the selected materials were obtained from environmental product declaration (EPD) files and literature studies (Marais et al. 2021). Thermophysical properties of three different exterior wall alternatives are given in Table 1. According to TS 825, the U value for the 1st degree day zone is 0.66 W/m²K and the designed wall configurations are below this value. The values specified in TS 825 standard were taken as the basis for the selection of roof, flooring, windows, and doors in accordance with the selected material.

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Table 1. Wall configuration of the selected materials (A0X: Alternative 0X)

AAC	Materials for A01	Thickness (m)	Density (kg/m³)	Thermal conductivity (W/mK)	Specific heat (J/kg K)
	Exterior plaster	0.03	1000	0.4	1000

	Total wall thickness (m)	0.3			

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

The unit embodied energy and carbon values are given in Table 2. Since the EPD for 3DP-LWFC is not available, the embodied energy and carbon values of this material are not known and the results for this material only cover the B6 stage. In the conclusion part, the outputs obtained are given from the point of 3DPC and then in comparison with 3DP-LWFC. The volume of the materials used in the building was taken by using 'schedules' in the Revit program.

Table 2. Embodied energy and carbon values for production stage (Ytong EPD, 2015; Saray Brick EPD, 2022; Akdağ EPD, 2022; Sikacrete EPD, 2022)

Material	Functional Unit	System Boundary	Embodied energy intensity (MJ)	Embodied carbon (kgCOe)
AAC	m ³	A1-A3 (cradle to gate)	1342.6	167.1
Brick	m ³		4779.7	425.7
3DPC	m ³		19737.0	829.6
Mineral wool	m ³		1010.3	82.0
3DP-LWFC	-		-	-

The system boundaries covering the production (A1-A3) and use (B6) phases for the relevant materials are shown in Figure 2. The most energy-intensive processes of the materials were marked in red. As cement is heated at high temperatures, it can result in significant energy consumption. The portland cement ratio of AAC is between 15-30% by mass. Even if there is no cement in hand-made brick, the long-lasting baking process of the brick (13 hours) can also increase the energy demand. The melting process of the ingredients of mineral wool at temperatures higher than 1500°C should be considered in terms of energy requirement. It should be noted that in the EPD file of 3DPC, the worst-case scenario results of the product were taken into account for the embodied stage. The inorganic binder mass ratio is stated to be between 2-98%. In this case, more than 90% of cement could have been used (Figure 2).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Figure 2. System boundaries of the AAC, brick, mineral wool and 3DPC

3. FINDINGS and DISCUSSION

The energy and carbon emission values obtained for each of the three façade alternatives were analyzed for the processes of extracting the raw material (A1), transporting the material to the factories for processing (A2), manufacturing the building material (A3) and using in the building (B6). Accordingly, it is seen that the ranking in terms of embodied energy and carbon values spent for the production phase is AAC, brick, and 3DPC from better to worse (Table 3).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Table 3. Embodied energy and carbon values in the A1-A3 stages

Materials	Volume (m ³)	Embodied Carbon (kgCO ₂ e)	Embodied Energy (MJ)
AAC	26.48	4,425	35,552
Total (A01)		4,425	35,552
Brick	22.98	9,782	109,838
Mineral wool	6.72	551	6,789
Total (A02)		10,333	116,627
3DPC	20.33	16,866	401,253
Mineral wool	11.2	18	11,315
Total (A03)		17,784	412,568

Since the energy values spent during the use phase of the building were obtained from the Design Builder program in kWh, the relevant values were multiplied by a factor of 3.6 and converted to MJ; thus, it was aimed to evaluate the energy consumption of the building in pre-use and during use stages together. In order to calculate the amount of energy consumed by the building during its lifetime, the service life of the building was assumed as 50 years. According to the results, the reduction in U-values by almost half in the 3DPC option led to a gain of 3.9% and 0.9% in primary energy consumption from heating, cooling, hot water, and lighting during the use process compared to AAC and brick, respectively (Table 4).

Table 4. Operational energy consumption in the B6 stage (DHW: Domestic hot water)

AAC (A01)	Lightening	Heating	Cooling	DHW	Primary Energy use
MJ/m ² /year	28.7	136.4	96.8	42.0	304.1
For the entire service life (MJ, 50 years)					1,520,363
Brick (A02)	Lightening	Heating	Cooling	DHW	Primary Energy use
MJ/m ² /year	28.9	128.6	95.2	42.2	295.0
For the entire service life (MJ, 50 years)					1,474,956
3DPC (A03)	Lightening	Heating	Cooling	DHW	Primary Energy use
MJ/m ² /year	24.9	138.3	92.8	36.4	292.2
For the entire service life (MJ, 50 years)					1,461,042

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

In terms of annual carbon emissions from energy consumption, the building alternative with AAC emits 3.5 tons of carbon per year, with brick 3.4 tons, and with 3DPC 3.3 tons. The gains in the case of 3DPC are 6.3% and 4.8% compared to AAC and brick, respectively (Table 5).

Table 5. Annual operational carbon emission in the B6 stage

Annual operational carbon	A01	A02	A03
Total (kg)	3,539	3,484	3,317

In A03, the energy requirement during the production phase of the building may be higher than the others due to the fact that 3DPC contains cement as an inorganic binder (2-98% by mass) and this ratio is kept high due to the worst-case scenario as stated in the EPD file. The reason for the rise of the brick may result from the baking process lasting for 13 hours. In terms of annual operational energy, AAC requires slightly more energy than the others while 3DPC exhibits a less energy-intensive attitude thanks to its thicker layer of insulation. In line with energy use, carbon emissions are in the same sequence (Figure 3).

Figure 3. Energy and carbon performance of the wall alternatives

Considering the total energy need of the building within the scope of 50 years of the life cycle, the energy distributions were 1,555 GJ for A01, 1,591 GJ for A02, and 1,873 GJ for A03. Considering 50 years of life cycle, 3DPC causes energy losses of 20.4% and 17.7%, compared to AAC and brick, respectively. In terms of global warming potential, it leads to a 1.26% rise compared to AAC, whereas a 0.45% of reduction compared to brick (Table 6).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Table 6. The total energy use of the wall alternatives and savings of 3DPC

Wall alternatives	Operational Energy (MJ, B6, 50 years)	Embodied Energy (MJ, A1-A3)	Life Cycle Energy (MJ)
A01- AAC	1,520,363	35,552	1,555,915
A02- Brick	1,474,956	116,453	1,591,409
A03- 3DPC	1,461,042	412,568	1,873,610
Saving compared to AAC (%)	3.9	-1060.5	-20.4
Saving compared to Brick (%)	0.9	-253.7	-17.7
Wall alternatives	Operational Carbon (MJ, B6, 50 years)	Embodied Carbon (MJ, A1-A3)	Life Cycle Carbon (MJ)
A01- AAC	176,955	4,425	181,380
A02- Brick	174,200	10,318	184,518
A03- 3DPC	165,890	17,784	183,674
Saving compared to AAC (%)	6.3	-301.9	-1.26
Saving compared to Brick (%)	4.8	-72.1	0.45

The reason for the low energy gain (0.9%-3.9%) of 3DPC in the use phase despite the 10 cm insulation layer may be the low thermal properties of the material. Therefore, the second part of this study aims to compare 3DP-LWFC, which has higher thermal performance, with other building materials. Since the properties of 3DP-LWFC were taken from a study (Marais et al. 2021), an EPD file for the same material was not available. Therefore, comparisons are only considered for the use phase (B6). The primary energy consumption of the structure built with this material and the gains obtained compared to other alternatives are given in Table 7.

Table 7. Operational energy consumption, annual carbon emission and savings of 3DP-LWFC

Foam concrete 3DP-LWFC (A04)	Lightening	Heating	Cooling	DHW	Primary Energy use
MJ/m ² /year	28.5	114.1	90.7	41.7	274.9
For the entire service life (MJ, 50 years)	1,374,462				
Annual operational carbon (kg)	3,308				
Savings of 3DP-LWFC;	Operational Energy Savings (%)	Operational Savings (%)	Carbon		
Compared to A01 – AAC	9.6	6.5			
Compared to A02 – Brick	6.8	5.1			
Compared to A03 – 3DPC	5.9	0.3			

According to the results, 3DP-LWFC has better energy performance with a gain of %9.6 compared to AAC; %6.8 compared to brick, and %5.9 compared to 3DPC. These gains reflected the carbon emissions a reduction of %6.5, %5.1, and %0.3, respectively. As can be seen from the results, superior thermophysical features enhance energy savings. Therefore, the development of higher quality energy-efficient materials would help to reduce energy demand.

4. CONCLUSION and RECOMMENDATIONS

Developments in technology guide architectural design and material selection processes. Thanks to 3D printing technology, which is one of these developments, it is possible to construct living spaces more economically and quickly, based on fewer labor requirements and with fewer waste problems. In addition to all these criteria, this study aims to test the effects of 3DPC on global warming potential and consumption of energy resources within the scope of environmental sustainability. For this purpose, the energy consumption and carbon emissions of AAC and brick, which are the most preferred contemporary building materials in Turkey, were evaluated in the embodied and operational processes with 3DPC.

According to the results, it has been observed that 3D printing technology, which offers advantages in many aspects, does not provide the desired results in terms of lifetime energy consumption and carbon emissions. AAC and brick are much more environmentally friendly than 3DPC, especially during the production phase. However, this may be because, as stated by the company, the worst-case results are included in the EPD file of the material.

In the second part of the study, the energy and carbon performances of foam concrete with improved thermal properties in 3D printing, as mentioned in another study, were evaluated separately for the use phase of the building. Thus, the effects of improved properties such as thermal conductivity, density, and specific heat on energy performance were examined. As a result, it was found that energy gains were increased by 2 to 7 times and carbon emissions were reduced, albeit negligibly. Since there is no EPD file for 3DP-LWFC, the energy and carbon levels during the production phase could not be evaluated.

The results of the study show that standard 3DPC does not have the lifetime energy performance to compete with contemporary building materials, but the gap can be closed with new-generation materials with improved thermal properties, such as foam concrete. In addition, the use of cement-free materials can reduce embodied energy.

Prospectively, life cycle phases can be studied more comprehensively, considering hazardous waste, initial investment, maintenance, and repair costs, and the consumption of other resources such as water and raw materials. By comparing new generation and/or traditional materials that are widely used today, it is possible to reveal their advantages and broaden the perspective of material producers to enable the production of materials that are environmentally friendly, have high energy performance, and offer convenience in many other ways.

ABSTRACT

In the world, 40% of the energy use and 30% of greenhouse gas emissions are caused by the construction industry. Buildings consume both embodied and operational energy during their entire life cycle. Recently, measures have been taken to reduce both types of energy. However, to make further progress, it is necessary to know the current stage. Therefore, the major objective of this study is to provide the theoretical background for future research by conducting a bibliometric analysis of 122 publications from the Web of Science (WOS) database over the last ten years. Results were examined under four key themes that emerged from the publications that reviewed: research topics, building types, software & databases, and materials. The studies comprise embodied and operational energy conducted in various research fields such as energy, carbon, cost, climate, comfort, design alternatives, etc., using a whole range of databases and software programs. The building types were studied according to their height, size, function, refurbishment, and certification status. Although there are studies carried out on the whole building scale, some of them were conducted on the material scale that consists of traditional, contemporary, prefabricated, recycled, or green building substances. As a result, it was concluded that buildings should be examined from a holistic perspective at the design stage in order to determine resource use, environmental impacts, budget, and user comfort.

Keywords: Operational Energy, Embodied Energy, Life Cycle Assessment, Buildings, Bibliometric Analysis.

1. INTRODUCTION

Evidence of global warming and climate change has become clear, with 2014 being the warmest year on record (dating back to 1880) and most of the warmest years after 2000 (R. H. Crawford, Bartak, Stephan, & Jensen, 2016). To address this critical challenge, there is a need to reduce greenhouse gas emissions, and buildings play a crucial role in this effort. In developed economies, buildings alone account for 30-40% of the primary energy demand and construction is one of the most energy-intensive sectors (IEA, 2022). Construction sector is the primary contributor to carbon emissions, accounting for 40% of energy-related emissions. Within this 40%, 12% is attributed to embodied carbon related to various building life cycle stages. The remaining 28% represents carbon offset, originating from energy usage in building operations,

September 14-15, 2023, Naples, Italy

including heating, cooling, and electrical appliances (Azis, Memon, Rahman, Nagapan, & Latif, 2012; Khan et al., 2022; Soust-Verdaguer et al., 2022).

If significant improvements in building efficiency are not made, greenhouse gas emissions from the construction and building industry could double in the next 20 years due to urban sprawl (UNEP, 2009). The carbon emissions and energy use associated with buildings occur throughout their life cycle, including material extraction, manufacturing, construction, operation, and end-of-life (Ramesh, Prakash, & Shukla, 2010). Building construction and operation consume a considerable amount of energy and have a great environmental impact (R. Crawford, 2011). Embodied energy and operational energy are two critical concepts for environmental sustainability. Embodied energy refers to the energy consumed in the production of building materials and includes the total energy required for the extraction, processing, production, and transportation of materials. On the other hand, operational energy refers to the energy consumed in the use stage. Embodied energy plays a critical role in design and material selection by determining the environmental impacts of building materials in their production processes, whereas operational energy is a critical factor in improving the energy efficiency of buildings and moving towards low-carbon energy sources. Rapid population growth and urbanization further exacerbate the pressure on natural resources and the environment, as the construction sector currently accounts for approximately 36% of global energy consumption and 40% of process-related emissions (IEA, 2018). Considering that buildings consume nearly half of the global energy each year and contribute significantly to carbon emissions, it is important to develop more sustainable and resource-friendly solutions within the construction sector (Poveda & Young, 2015; Schandl et al., 2018). The concentration of carbon in the atmosphere has reached record levels, leading to noticeable global warming and extreme weather events. Therefore, urgent action is needed to investigate energy performance during the building life cycle.

Bibliometrics is a method used to assess the structure and development of scientific fields or to map and analyze specific disciplines (Boyack, Klavans, & Börner, 2005). Bibliometric research evaluates the data obtained using various statistical techniques (McBurney & Novak, 2002). These evaluations are carried out via various research parameters such as publication years, research topics, authors, institutions, keywords, citations, and research methods. These reviews are accompanied by findings to assess the current status and development over time of a discipline, book, journal, paper, institution, country, etc. (Pritchard, 1969). Furthermore, through various bibliometric indicators, the scientific publishing behavior and dynamics of countries, universities, and institutes can be determined (Pechlaner, Zehrer, Matzler, & Abfalter, 2004).

This study provides a systematic literature review that aims to identify key issues and factors in building embodied and operational energy. In the study, the following research objectives are pursued:

1. By using bibliometric analysis, identifying commonly used keywords, key concepts, most influential authors, universities, countries, and articles.
2. Reviewing and summarizing the current trends, practices, and limitations related to operational and embodied energy in buildings.

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

3. Focusing on the results of the study by identifying potential solutions to the identified problems, future research topics, and opportunities.

2. MATERIALS and METHODS

To investigate the state of the art of operational and embodied energy analysis in building life cycle, the most frequently used keywords are determined to describe the subject. ("Life Cycle Energy" OR "Life Cycle Carbon" OR "Life Cycle Assessment" OR "LCA") AND ("Building" OR "Construction") in the title, AND ("Embodied" AND "Operational") in the title, abstract, and keywords, between 2013 and 2023 index to search are analyzed. The language, "English" was selected and chosen document type "Article" OR "Review" was examined with VOSviewer and Bibliometrix, software tools for visualizing and obtaining bibliometric datasets. Keywords, language, and research field limitations apply to the research criteria (Figure 1). The most frequently cited articles, authors, countries, years of publication, the total number of publications by country, research area, sources, organizations, factor analysis, frequently used keywords, and content are examined in the literature review analysis on operational and embodied energy analysis of building life cycle in the construction industry. Web of Science database is used to obtain an accurate and reliable bibliometric network. Based on the analysis of the WOS database, 122 articles were found to be indexed SCI-Expanded, SSCI, ESCI, and A&HCI. The summary of the methodology can be seen in Figure 1.

Figure 1. Methodology of the scientific review

Before proceeding with visual and scientific mapping, it is necessary to briefly evaluate the documents that constitute the universe of the study. According to analysis, the annual growth of published research is 17.46% and there is an average of 26.39 citations per publication. 122 publications were obtained as a result of the research criteria on operational and embodied energy throughout the life cycle of buildings with a total of 365 authors and 33 sources of publication.

3. FINDINGS and DISCUSSION

In this section, the results of the bibliometric analysis are presented in detail. The analyses provide a comprehensive view of the current state and development of the discipline, offering

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

valuable insights to researchers, academics, and relevant stakeholders. These results provide information for future researchers in related fields.

3.1. Annual Publication Analysis

The distribution of the number of studies throughout time is a key factor in determining the depth of a subject. Figure 3 shows the total number of publications in the period 2013-2023. It is observed that among 122 publications on this subject, 13% of them were published in 2020 and 16% in both 2021 and 2022. The sustainable development goals in the EU and the importance of this issue in other countries around the world in recent years have played a major role in this situation.

Figure 3. Distribution of publications by years

3.2. Country Analysis

Analyzing publications by country helps to understand how important the topic is in which countries. The 122 articles were produced in 33 countries in total. The United States of America (USA) has the highest number of publications with 30, followed by China with 29, and Australia with 28. It is seen that developed countries are more inclined towards this topic than developing countries (Table 1).

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

Table 1. Distribution of the number of publications by country

<i>Rank</i>	<i>Country</i>	<i>Publication</i>	<i>Rank</i>	<i>Country</i>	<i>Publication</i>
	United States of America (USA)	30		Canada	7
<i>1</i>			<i>11</i>		
<i>2</i>	China	29	<i>12</i>	Spain	7
<i>3</i>	Australia	28	<i>13</i>	Turkey	7
	United Kingdom (UK)	21		Denmark	6
<i>4</i>			<i>14</i>		
<i>5</i>	Belgium	17	<i>15</i>	Norway	6
<i>6</i>	Italy	13	<i>16</i>	Germany	5
<i>7</i>	India	11	<i>17</i>	Iran	4
<i>8</i>	Switzerland	10	<i>18</i>	Sweden	4
<i>9</i>	Portugal	8	<i>19</i>	Chile	3
<i>10</i>	Austria	7	<i>20</i>	Finland	3

A study is a continuation of previous studies and each study is a part of the literature. For this reason, giving and receiving citations is a very important issue in terms of ensuring the visibility of the research in the scientific field and pioneering future studies. Figure 4 shows the top 20 most cited countries in the field. With 518 citations, it is seen that the most cited articles are from Australia.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 4. Top 20 most cited countries

3.3. Author and Affiliation Analysis

The citations made by authors are important not only for identifying the most influential authors but also for determining the influence of the author on other works. For this reason, universities or organizations attach great importance to publishing articles to increase their effectiveness and visibility in the scientific world. In Table 2, the list of the top 10 most highly cited authors and the organizations that produce the most articles can be seen. The top 5 most cited authors and pioneers in the field are respectively "A. Stephan" 357 citations, "R. H. Crawford" 234 citations, "A. Garcia-Martinez" 225 citations, "B. Sanchez-Montanes" 225 citations, and "A. Vilches" 225 citations. The top 3 organizations with the most publications in the Web of Science database are "University of Melbourne", "Graz University of Technology", and "KU Leuven". This data guides in assessing the importance and impact of studies in the scientific world and is an important reference for relevant researchers and institutions.

Table 2. Top 10 most cited authors and the top 10 organizations with the most publications

<i>The most cited author</i>				<i>The most productive affiliations</i>			
Rank	Author Name	Citation	H-Index	Rank	Affiliation Name	Publication	Citation
1	A. Stephan	357	6	1	University of Melbourne	11	333
2	R. H. Crawford	234	6	2	Graz University of Technology	7	61

3.4. Source Analysis

Examining the top 10 platforms with the highest number of publications in the reviewed literature is necessary in terms of understanding the degree of interest of the sources in the subject. The top 3 journals with the highest number of articles are "*Energy and Buildings*" with 23 articles, "*Building and Environment*" with 12 articles, and "*Buildings*" with 10 articles (Figure 5).

Figure 5. Top 10 sources with the highest number of publications

The three-field plot (TFP) is used to display the relationships between keywords, sources, and countries. The diagram's main characteristics are represented by rectangles of a different hue. The height of the rectangles in the TFP diagram is determined by the sum of the relationships occurring between the component of the rectangle (keywords, source, and countries) and other

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

parts of the diagram. The higher the rectangle representing the component or element, the more relationship it has to other concepts it is connected to. Figure 6 depicts the TFP analysis of publications on life cycle assessment, which focuses on the relationships between keywords, sources, and countries. The graphic demonstrates the relationships between the top countries (*China, Australia, etc.*), the leading journals (*Energy and Buildings, Buildings, etc.*), and top keywords (*life cycle assessment, embodied energy, etc.*).

Figure 6. Relations between keywords (left), source (middle), and countries (right)

3.5. Keyword Analysis

A keyword analysis is substantial for understanding the content and scope of a study. The mapping of the keywords repeated 1 or more times is given in Figure 7. In the mapping, 396 keywords used in the publications were examined to determine the relationship, frequency, and total link strength of keywords using VOSviewer. It is seen that 2 main clusters in the keywords are formed within the framework of "life cycle assessment" indicated by the gray cluster and "embodied energy" indicated by the red cluster.

September 14-15, 2023, Naples, Italy

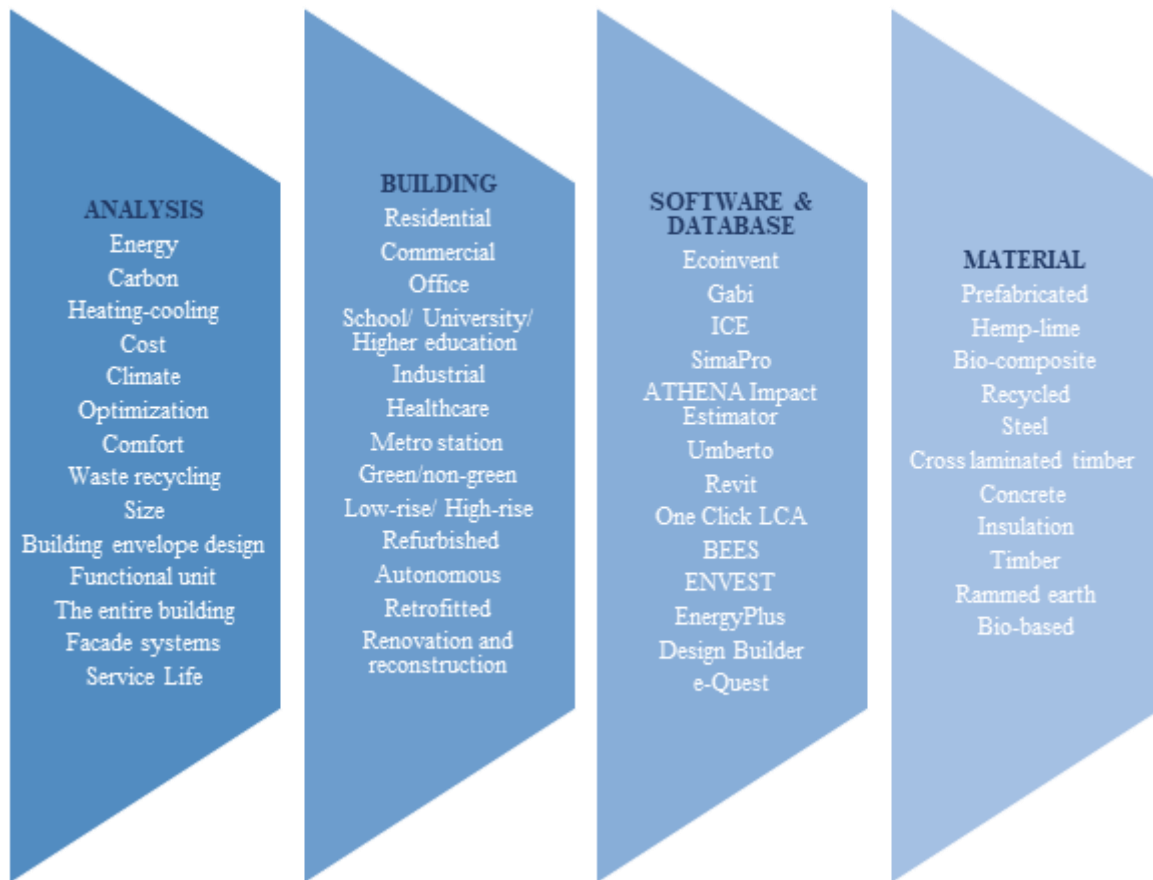

Figure 8. Trend topics of the publications

The conclusions drawn from the studies examined in detail are as follows:

- Building floor area affects the amount of recurring, total embodied energy and life cycle energy. In addition, total embodied energy may increase with the increase in the size of the house (Dixit, 2019).
- Measures to reduce operational energy are important to quantify the life cycle energy and cost over the service life of the building (Stephan & Stephan, 2016).
- Prefabricated buildings have an average embodied carbon reduction of 15%, and an average operational carbon reduction of 3.2% (Teng et al. 2018).
- Minimizing life cycle energy requires consideration of the building's embodied energy as well as heating and cooling energy. It has been determined that about 25% of the total life cycle energy of the building is due to embodied energy, especially in warm climates (Karimpour et al., 2014).
- The choice of building materials and design features affect the life cycle energy of the building (Abd Rashid & Yusoff, 2015).
- In a sensitivity analysis conducted in a study, it was found that the use phase of the building makes the largest contribution to carbon emissions (Peng, 2016).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

- In the case of building renovation, the use of new materials accounts for 10% to 60% of the total energy requirement. In renovation scenarios, the total energy requirement for the remaining life cycle of the building is reduced by 30% to 80% compared to the non-intervention case (Vilches, Garcia-Martinez, & Sanchez-Montanes, 2017).
- Life cycle assessment studies on low-rise buildings, especially on residential buildings, are numerous. However, in the life cycle assessment of high-rise buildings, commercial buildings are at the forefront (Bahramian & Yetilmezsoy, 2020).

4. CONCLUSION and RECOMMENDATIONS

The findings of this study show that research on building materials, design features, and energy use should be more focused on moving towards sustainability goals in the building sector and minimizing negative impacts on the environment. Improving buildings in terms of energy efficiency, environmental compliance, and user comfort will be an important step towards a more livable environment for future generations. Therefore, the research and studies in the building sector would contribute to raising awareness of sustainability and promoting green buildings.

In line with the results obtained, it is seen that it is necessary to adopt a holistic approach at the design stage to determine essential elements such as resource use, environmental impacts, budget, and user comfort. This comprehensive assessment will contribute to making buildings more efficient and environmentally friendly in terms of architectural sustainability.

Future studies could focus on the determinants of energy use and examine how energy consumption levels vary according to climate, building size, building height, and building age. It would also be an important area of research to examine the energy performance of different kinds of buildings in detail and make comparisons between developing and developed countries.

ABSTRACT

With the growth of cities, it has become inevitable for areas and structures that have lost their function in the center to transform together with their environment and gain different functions. Each of the structures with different functions in the historical surroundings of the cities is a cultural heritage as it carries the traces of the period in which they were built. For sustainable cultural heritage, the social, cultural, historical and architectural values of these structures must be preserved and thus transferred to future generations. Re-functioning in historical texture is an important area of interior design. Due to the importance of the subject, an experimental workshop was conducted with the participation of 12 students within the scope of the Interior Space Organization elective course of the Department of Architecture at Gaziantep University. This study covers the re-functioning of the Cenani Mansion, which is located in the historical city center of Gaziantep, in order to sustain its cultural heritage. At the end of the workshop, interior designs that take into account the preservation of the historical texture and the existing structure were revealed. It has been determined that the theoretical knowledge transferred to the participant students throughout the process, workshops and their own researches are reflected in the final products. With this workshop, it is aimed to gain design practices in order to think about the protection of historical buildings, which are our cultural heritage, and to function them with the right architectural solutions.

Keywords: Cultural Heritage, Sustainable Design, Refunctioning, Interior Design, Cenani Mansion.

1. INTRODUCTION

Integrating architectural heritage, which is one of the most important components of cultural heritage, with contemporary life is important for the cultural continuity of societies. Re-functioning of buildings registered as architectural heritage without compromising their identity and authenticity is one of the most preferred conservation methods today. The reuse of architectural heritage is about negotiating the transition from the past to the future to secure the historical transfer of heritage assets while also meeting the needs of the contemporary world (Chapman 2004). Considering that re-functioning rather than demolishing the building extends the life of the building (Yıldırım and Turan, 2012), the method serves the understanding of conservation in the context of both ecological and social and cultural sustainability (Tuğlu Karslı and Aytis, 2019). Ecologically, while the practice of adapting it to a new function takes into account the amount of waste that will arise during demolition, the amount of energy and materials to be consumed (Elsorady, 2013), the building, which has continued its life in a socio-cultural dimension, participates in urban life by transferring the traces of the period it was built

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

to the new environmental context (Gazi and Boduroğlu, 2015). Heritage conservation, in turn, contributes to ecologically sustainable development (Pearson & Sullivan, 1999).

Re-functioning is the adaptation to a different function of historical buildings with function destroyed due to changing lifestyles over time and linked desires or the updating of historical buildings that are below standards due to continuing function but old standards of comfort. (Ahunbay 2011). "Cultural assets may be refunctioned in line with current needs, but this should be performed in a way respectful to, and without harming, the existing artistic, original, and historical features" (ICOMOS, 1965). In this reuse process, buildings must be raised to an acceptable standard of living while respecting their authenticity, integrity and meaning. (ICOMOS, 2013)

When assigning a "new function" to a structure:

- Spatial formation of the building (plan scheme)
- The volume dimensions of the building (interior dimensions of the building)
- Attention should be paid to the internal circulation of the building (Altınoluk, 1998)

In this study, the process and results of a workshop for the re-functioning of the Historical Cenani Mansion are shared. In the workshop, it was aimed for the students of Architecture to understand the practice of re-functioning in order to sustain the cultural heritage and to comprehend the methods of interior design in historical buildings. This study, which includes practices for re-functioning that should be included in architectural education practice, aims to create a document for future research.

2. MATERIALS and METHODS

For this study, Cenani Mansion located in the historical neighborhood of Gaziantep was chosen. The reasons for choosing this building are that it reflects the history and culture of the surrounding area, that it has gained many different functions from the past to the present, and that the building has been well preserved until today. In the study, literature information on the subject, the history of Cenani Mansion, the workshop process and the results of the idea projects will be shared. The workshop consists of the students' re-functioning of the Cenani mansion within the scope of the Interior Space Organization elective course of the Department of Architecture of Gaziantep University. The participants, consisting of 12 students who took the course, carried out their studies in groups of 4 people.

During the workshop, Cenani Mansion and its surroundings were visited and examined with the students. After examining the survey, restoration projects and other documents taken from KUDEB of Cenani Mansion, which is used as a cultural center by gaining a new function today, theoretical information about re-functioning was given to the students. At the end of the workshop, the function given to the historical urban texture and the original architectural structure of the mansion and the problems that may occur afterwards were questioned at the end of the workshop.

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

The flow of the workshop process was followed with the table below:

↑	The importance and justifications of the concept of re-functioning in the historical environment
	Analysis of the existing historical building and its surroundings
↓	Discussion on re-functioning proposals
	Interior design of the re-functioned building
	Conclusion and evaluation

Description of Building

Cenani Mansion located between Bey and Eyüboğlu neighborhoods of Gaziantep, the southern part of Turkey, was built in 1870.

Fig. 1. Location of Cenani Mansion (Google Earth)

It is a two-storey building made of cut stone (havara stone), which consists of two courtyards and four buildings. There are shops under arched openings on the ground floor of Cenani Mansion. A round-arched door opens to the courtyard of the Mansion. There are pomegranate, apricot, mulberry, plum, apple, fig and pine trees in this large courtyard. The courtyard of the house is entered through a round arched door with a decorative keystone protruding outwards. With its triangular pediment and profiled facade windows, the building has a characteristic architectural originality.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Fig. 2. (a) street facade of the building,

(b) courtyard of the building

The Cenani Mansion was registered on 10.03.1997 and it was donated to Gaziantep University by the Cenani family in 2010. The building, whose restoration was completed on September 30, 2011, was put into service as Gaziantep University Cenani Mansion Culture and Art Center, and serves as one of the most important culture and art centers of the city with the exhibitions and artistic events.

3. FINDINGS and DISCUSSION

Within the scope of the workshop, students were asked to propose a function for the historical Cenani Mansion and to work on the adaptation of this new function to the space. In this section, 3 proposal projects developed within the scope of the workshop are included. Each proposal consists of the work of a group of 4 people. Students presented these works with interior project expression tools (moodboard, material board, rendered plans, lighting plan, sections furniture details and 3d views).

Proposal 1: Architectural Atelier

The group that developed this proposal determined the concept of the design as the contrast of the historical texture and the new. The rationale for the new function; is the need for a place where architecture students can do their work outside of school. In the space design, the modern atmosphere of the new is reflected within the outer borders of the historical mansion. In the interior project, furniture and lighting elements were designed in line with the needs of the function.

Fig 7. Proposal 1: Architectural Atelier- furniture details

Proposal 2: Boutique Hotel

The group that developed this proposal built its design concept on simplicity and comfort. The rationale for the new function; to keep the historical texture of Gaziantep alive through tourism. While commercial functions are located on the facades facing the street on the ground floor, an administrative office, kitchen and 5 hotel rooms are designed on the upper floor. There is a restaurant in the courtyard. The colors used in the design are pastel and earthy tones. Furniture for hotel room bed, nightstand, closet, etc. and the tables and chairs for the restaurant were designed by the students in a simple line.

Proposal 3: Book store-cafe

The group that developed this proposal built the design concept on the principles of modernism. The rationale for the new function; It has been determined for the residents of the neighborhood where the mansion is located, for the need for the combination of book sales and cafe functions. On the ground floor, there are book sales shops on the facades facing the street, and on the upper floor, reading rooms and a group study room. There is a cafe and seating units in the courtyard. The colors used in the design are white and earth tones. The furniture is designed with clean, sharp lines reflecting the language of modernism, with metal, wood and glass materials.

4. CONCLUSION and RECOMMENDATIONS

Within the scope of the study, the workshop conducted for the re-functioning of the Cenani Mansion located in the historical Bey Mahallesi of Gaziantep city was examined. In this workshop, which was carried out with architecture students, the existing historical building was examined with visual and physical analysis, and the interior design was realized together with new functions, with three different functions being assigned. In the workshop, creating architectural solutions required by the new function by preserving the existing structural elements has been the primary criterion in ensuring the continuity of the historical texture and the social and cultural sustainability of the building.

As a result of the study, it was observed that the students had insufficient knowledge on this subject at the beginning of the workshop and the existence of innovative and creative ideas. Although the explanation of interior design through re-functioning is insufficient for the duration of the current course, it has been observed that a minimum of knowledge has been formed as a result of the theoretical information conveyed to the students during the workshop and the discussions made so that they can make original designs.

Giving students the awareness of the protection of the historical environment and buildings by practicing with different courses is important in terms of creating awareness. Since it is possible for them to encounter the problem of new building design in the historical texture in their professional life, it is certain that students who have been trained in conservation and re-functioning will make the right decisions about transmitting cultural assets to future generations.

As a result, it is inevitable that the historical and cultural environments of cities will become obsolete and function changes over time. Revitalizing historical buildings with new functions in line with the needs of the place where they are located, meeting the needs of the users and adapting them to their environment are important for the sustainability of our cultural heritage.

Note: The survey and restoration projects of Cenani Mansion have been taken from KUDEB, Gaziantep Metropolitan Municipality, Department of Conservation, Implementation and Inspection. (Fig.3 and Fig.4).

ABSTRACT

The dome and domed structure, one of the indispensable symbolic and functional elements of world architectural history from the earliest ages to the present day, is also one of the important building elements of Turkish-Islamic architecture. From the 14th century onwards, the Ottomans, who settled in Anatolia, started the development process of the domed space type in Anatolia by synthesizing the building culture of Islam and the Seljuks with the local materials of Anatolia and their own building culture. The domed central space is an important element of Turkish mosque architecture, and many original experiments were carried out in this direction. From the 15th century onwards, the dome ceased to be a covering element and became one of the most important symbols of Ottoman architecture. The dome architecture, which reached its most monumental form in terms of size and load-bearing system in the Classical Ottoman period, especially in the buildings designed and built by Mimar Sinan, continued to be used and diversified in the Late Ottoman and Early Republican periods. This diversity varies according to regions, localities, and time. The domes, in the construction of which various materials such as stone, brick, wood, and iron were used, were built with bagdadi technique in some of the mosques built in the 19th century and early 20th century. This study discusses some mosques in the center and districts of Çankırı Province whose domes were built with bagdadi technique. The study starts with a literature review on Çankırı. The study starts with a literature review on Çankırı. Then it continues with a literature and field study on the mosques that constitute the subject of the study. The architectural features of these buildings are emphasized and the bagdadi dome is discussed. These buildings with similar architectural features are dated to the late nineteenth century.

Keywords: Çankırı, Baghdadi Dome, Mosque, Late Ottoman Architecture.

1. INTRODUCTION

Çankırı, which is located between the Kızılırmak and the Western Black Sea basins in the north of the Central Anatolia Region, spreading over a wide area between the Ilgaz Mountains in the north and the Middle Kızılırmak Basin in the south, is a bridge connecting Central Anatolia and the Black Sea regions (Yurt Ansiklopedisi, 1982). The city of Çankırı is located in the region known as Paflagonia in history (Başer, 1956). We learn the first written information about Çankırı and the Paflagonya region in which it is located from Strabon's "Geography" in the 7th century BC (Strabon, 1993). After the 1071 Malazgirt Victory, while the raids to Anatolia continued, Suleiman Shah, the founder of the Anatolian Seljuk State, and his commanders began to capture many settlements in Anatolia. Emir Karatekin, one of the commanders of Süleyman Şah, conquered Çankırı and its surroundings in 1082-83 (Sevim, 1993). Between 1132 and 1140, due to the struggles between the Danishmendids, it changed hands several times between Byzantium and the Danishmendids (Alptekin, 1992). In 1142, during the reign of the Seljuk Sultan Mesut I, the regions of Ankara, Çankırı, Kastamonu, Kayseri, and Malatya were definitively annexed to the Anatolian Seljuk lands (Kankal, 2011). The city remained under the

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

sovereignty of the Anatolian Seljuks between 1142-1243, the Cobanids for a short time until 1290, the Candarids until 1461, and then the Ottomans until the Republican period. After the city was taken over by the Ottomans, it was in Çankırı Sanjak under the Anatolian province. After the 1861 Provincial Regulation, it became a province under Kastamonu Province (Varlık, 1991). In this study, 4 mosques in Çankırı Province, which were built in the bagdadi dome technique, were examined. These are Central Şeyhoğlu Mosque, Korgun Yolcaya Village Mosque, Orta Kalfat Hatipler Mosque and Ilgaz Gaziler Village Mosque.

2. INVESTIGATION OF BAGHDADI DOMED MOSQUES IN ÇANKIRI

Bagdadi dome applications are located under a hipped roof. For this reason, it is generally defined as a hidden dome or symbolic dome. It is also referred to as "imitation dome" in some studies (Pektaş, 2013). Bagdadi technique consists of laths or slats nailed horizontally at intervals of 1-2 cm between the uprights in timber frame structures and the bagdadi plaster mortar is applied on these wooden slats and adhered to the surface by entering between them (Sözen & Tanyeli, 1986; Arseven, 1983; Hasol, 2008). In mosque architecture, the bagdadi dome appears in the simplest form as the dome placed in the center of the wooden ceiling. The dome is placed between the roof trusses and protected by a hipped roof or gable roof. The fact that the wooden material is easily accessible, lightweight, and does not bring an additional burden to the structure, provides thermal insulation by protecting it from cold and hot, and prevents dampness and humidity has made the bagdadi technique preferred in domes (Muşmak and Çetinaslan, 2009: 463).

Baghdadi domed mosques, which are the subject of this study, have a very important place among the mosques in the center and districts of Çankırı Province, most of which date back to the Ottoman period. When the mosques in the city are examined, it is seen that most of them were built with masonry adobe or stone system and have a wooden flat ceiling system. Except for the Sultan Süleyman (Ulu) Mosque and Alibey Mosque in the center of Çankırı, there are no domed mosques built in brick or stone.

Şeyhoğlu Mosque (Figure 1): The mosque has a square plan (7.50x7.60 m harim space) with a 7.60 m diameter Baghdadi dome. The dome rests on an octagonal tambour/pulley (about 150 cm tambour height) with a wooden roof covered with tiles (Figure 2). The minaret is not original and was built in 1966. Today, it is known that two wooden panels in the Archive of Dr. Rıfki Kâmil Urgan Çankırı Research Center belong to Hacışeyhoğlu Mosque. According to these inscriptions, Hacışeyhzade and Hacı Pir Said built the mosque and madrasah and Hacı Said issued a foundation in H.1268 / 1851-52. According to the gravestone in the southeast of the hazard located on the east side of the mosque, it is thought that the mosque was built before 1829-30, the date of the death of Hacı Şeyhzade Hacı Mehmet, the founder of the mosque.

September 14-15, 2023, Naples, Italy

Figure 1. Exterior view of Şeyhoğlu Mosque (Karakuş, 2007)

Figure 2. North façade and B-B Section (Ankara Regional Directorate of Foundations Archive)

Orta District Kalfat Hatipler Neighborhood Mosque (Figure 3): The square-plan harim (interior measures 10.14x10.08 m) of the mosque has very high main walls and the dome is supported by a polygonal pulley/tambour. There are weight towers supporting the tambour at the four corners (Figure 4-5). The walls of the harim and the tambour end at the top with profiled stone eaves that gradually open outwards. There are eight windows in the tambour. The closed last congregation area of the mosque has three sections, all of which are domed and lead coated. The transitions to the main dome are provided with squinches at the corners and the arches rest on stone consoles and are supported by tension bars at the corner. The narrow promenade at the

base of the dome is surrounded by an iron railing. The wooden women's lounge in the north of the harim is supported by four wooden columns and the main wall. The graves of Hacı Derviş Osman, the founder of the minaret, Memişzade Ali Efendi, the founder of the mosque, and his two wives are in the courtyard. The double-balcony minaret stands slightly apart from the wall and bears traces of different periods. The minaret was built in 1858 AD. The part after the first balcony is reinforced concrete and not original.

Ilgaz- Gaziler Village Mosque (Figure 6): The rectangular (10,34x12,36 m interior dimensions), two-storey building with a hipped roof was built in H.1329/M.1905. The minaret in the northwest with a single balcony was built of cut stone in 1962. There is a last congregation place open on three sides in the north. The transition to the bagdadi dome is through squinches. There are windows with revzen on the dome tambour. The dome, dome transitions, walls, arches and windows are decorated with geometric and floral motifs (Figure 7) (Ayhan, 2012).

September 14-15, 2023, Naples, Italy

Figure 7. North façade and B-B Section (Archive of AVBB)

Korgun Yolcaya Village Mosque (Figure 8): There is no foundation registration or inscription about the construction date of the mosque. According to its architectural features and construction techniques, it is dated to the late 19th or early 20th century. The walls of the building, which has a rectangular plan scheme close to square (7,86x 7,82 m interior dimensions), are made of rubble stone. The harim space is covered by a baghdadi dome resting on an octagonal tambour/pulley. The transitions to the baghdadi dome are through pendants and the tambour is also formed by the baghdadi method (Figure 9). The smooth cut stone minaret base, adjacent to the west wall of the mosque, is adjacent to the west wall of the closed last congregation place continuing from the north.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 8. Exterior and interior view of Korgun Yolcaya Village Mosque

Figure 9. West façade and D-D Section

The Korgun-Mitik Mosque (Figure 10), which dates to the late Ottoman period, has rubble stone walls, a Baghdadi dome with squinches, an octagonal tambour and a tile roof. There are false arches connecting the squinches to each other. Korgun-Büyük (Old) Mosque has the same characteristics as Yolkaya Village Mosque in terms of dome features.

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

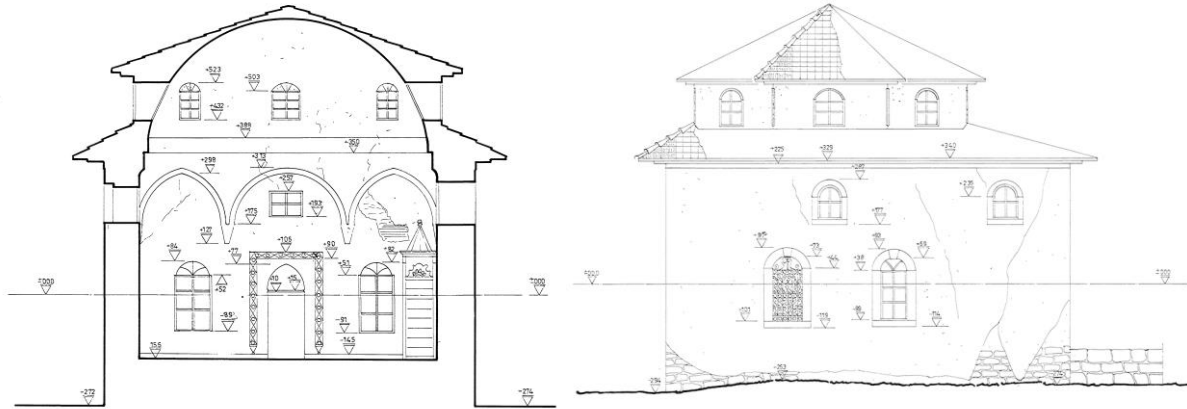

Figure 10. Korgun-Mitik Mosque B-B Section and East Façade

Kurşunlu-Şaban Ağa Mosque (Figure 11) was built in 1895. In the square-planned mosque, the baghdadi dome is placed on an octagonal tambour. The dome is decorated with hand-made floral ornamentation starting from the squinches, which are the transition elements of the dome. Korgun-Doğu Neighborhood Mosque, Yapraklı-Bugay Village Mosque and Yapraklı-Tatlı Pınar Village Mosque can also be given as examples. It is seen that these mosques also have octagonal tambours and octagonal domes with squinches as transition elements.

Figure 11. Kurşunlu Şaban Ağa Mosque A-A Section and East Façade

3. CONCLUSION and RECOMMENDATIONS

Within the scope of this study, the mosques with baghdadi domes in the center and districts of Çankırı, which were built in the second half of the 19th and early 20th centuries, were examined. The common point of the examined mosques is the use of rubble stone on the main walls and the application of wood in the tambura/drum and dome sections with the bağdadi technique. One of the important reasons for the use of the baghdadi dome in these buildings is that it does not bring an additional load to the structure due to the lightness of the wooden material and

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

provides thermal insulation against cold and hot. In fact, the fact that domed structures are both difficult in terms of labor and more costly if they are built of stone and brick is seen as an important reason for the construction of wooden flat-roofed mosques in this region. In the domed buildings, it is seen that wooden bagdadi domes were preferred, again considering the cost and workmanship. In some of these buildings, it can be said that in the 19th century, wall decorations in baroque, rococo, and empire styles, which emerged with the influence of western art in *kalemişi* work technique, were seen.

ABSTRACT

Plants in cities provide positive benefits in many areas such as regulating the urban climate, improving air quality, reducing noise, improving urban aesthetics, creating a natural environment and human health. Therefore, ornamental plants have become one of the important physical needs in urban landscaping. Today, interest in the production of ornamental plant seedlings is increasing day by day. However, nurseries should give importance to the quality of the produced seedlings rather than their quantity. Thus, the survivor rate can be increased in planting the produced seedlings. In this study, ornamental plants grown or found in Diyarbakir Forest Nursery were determined, seedling age, type and production method, the status of total seedling production and ecological tolerance levels of these plants were examined, and the opinions of nursery staff about the nursery were found out. It was revealed that the plant taxa in Diyarbakir Forest Nursery mainly consisted of 1+0 old bare-root ornamental plant seedlings and they were produced with seeding. In the nursery, the sale of forest tree species is more preferred than ornamental plants. It was found that most of the plant taxa (58%) had a moderate water consumption level. Cultural operations such as hoeing, thinning, irrigation, weeding, fertilization and transplanting are carried out in Diyarbakir Forest Nursery. In the nursery, the seedling production of plant taxa with low water consumption, natural distribution and ecologically tolerant should be preferred. This production will both increase the demand for seedlings from the nursery in landscaping in the region and will enable the plants to adapt more easily after planting.

Keywords: Forest Nursery, Ornamental Plant, Seedling Production, Diyarbakir.

1. INTRODUCTION

In today's world, buildings are being constructed without proper planning or consideration for urban values, leading to a distancing from nature and an increasing longing for it among people

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

(Özdalyan, 2022). The role of ornamental plants in creating a more livable environment is becoming increasingly important. The use of plants in cities provides positive benefits in terms of urban climate, air quality, noise reduction, urban aesthetics, creating a natural environment, and human health (Taştan, 2019).

Ornamental plants, defined as decorative plants produced for aesthetic, functional, and economic purposes, are categorized into cut flowers, indoor ornamental plants, outdoor ornamental plants, and natural flower bulb cultivation (Şimşek, 2015). Ornamental plants that establish a relationship between humans and nature in urban areas have become an important physical need, and there is a great interest in ornamental plant production (Karagüzel et al., 2010). In ornamental plant production, it is important to effectively direct region-specific plants to protect natural plants and ensure sustainability (Arslan, 2022). Therefore, knowing the morphological, physiological, and genetic quality characteristics of plant species is important for selecting and using ornamental plants with desired traits, as well as understanding the ecological conditions of the landscape areas where they will be used (Kösa, 2015). In general, producing high-quality seedlings suitable for site conditions increases their lifespan in the field (Alkan & Divrik, 2019)-

Previous studies have examined the opinions of nursery managers regarding the management activities in state forest nurseries (Alkan & Divrik, 2019), evaluated the woody plant species used in urban parks in Bursa based on ecological tolerance criteria (Zencirkıran & Seyidoğlu Akdeniz, 2017), and assessed the woody plant taxa in public green areas in the city center of Ordu based on water consumption levels and ecological tolerance criteria (Güzel & Ulus, 2021). However, there is currently no research available on the identification of existing ornamental plants and their ecological tolerance levels in the Diyarbakır forest nursery.

This study aims to determine the ornamental plants grown or found in the Diyarbakır forest nursery, including the age, type, and production method of plant species, the overall seedling production status, and the ecological tolerance levels of existing plants.

2. MATERIAL and METHOD

The research area selected for the study is Diyarbakır Forest Nursery. The nursery is located in Dönümlü Mahallesi, Diyarbakır-Yenişehir District (Figure 1). The total area of the nursery is 550,000 m², with 547,960 m² dedicated to seedling cultivation, 1800 m² for seedling sales, and 240 m² for greenhouse cultivation.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

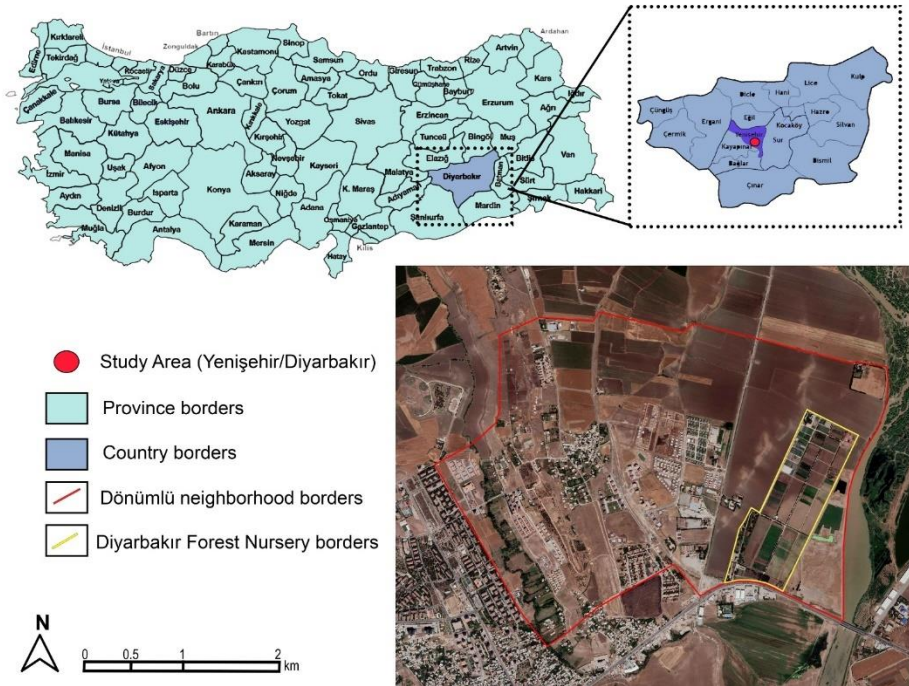

Figure 1. Location of study area

Diyarbakır province is located in the central part of Southeast Anatolia and in the northern region of Mesopotamia. It is situated at an elevation of 650 meters above sea level and 100 meters above the Tigris River (Diyarbakır Governorate, 2023). Based on 29 years of data, the average high temperature in Diyarbakır is 15.9 °C, the annual average rainfall is 493.3 mm, and the average number of days with snow cover is 13 (MGM, 2023).

In this study, the names and some information about the species grown or found in the nursery were provided by the nursery management staff. Official documents and records related to the nursery were consulted to obtain some of the information. Additionally, interviews were conducted with the nursery manager, engineers, forest conservation officers, and workers. When determining the plant taxonomy as forest trees and ornamental plants, the studies conducted by Ata (2022), OGM (2023), and Zencirkıran (2013) were referenced. The water consumption and ecological tolerance levels (tolerance to frost, heat, drought, salinity, pollution, and wind) were determined based on the studies by Zencirkıran and Akdeniz (2017) and Güzel and Ulus (2021). The ecological tolerance levels were classified into three categories: "1 = low tolerance," "2 = moderate tolerance," and "3 = high tolerance." Additionally, the plant taxonomy was grouped into five categories based on water consumption: "low," "low/medium," "medium," "medium/high," and "high" (Zencirkıran and Akdeniz, 2017).

3. RESULTS and DISCUSSION

A total of 26 taxa were identified in the study area. Out of these, 6 taxa (*Acer negundo* L., *Cupressus arizonica* L. 'Greene', *C. arizonica* L. 'Greene', *Fraxinus excelsior* L., *Platanus orientalis* L., *Pinus brutia* L.) are classified as forest trees, while 20 taxa are classified as ornamental plants. The identified taxa were further classified based on the age of the seedlings, type of seedling, and method of production. 22 taxa belong to the 1+0 age group, and 14 taxa

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

are bare-root seedlings. It was determined that 17 taxa are produced from seeds. The taxa produced through cutting propagation include *Buxus sempervirens* L., *Euonymus japonica* L., *Lycium barbarum* L., *Pyracantha coccinea* M. Roem., *Rosa chinensis* L., *Rosmarinus officinalis* L., and *Thuja orientalis* cv. 'Aurea Nana' (Table 1). The cutting collection and planting are generally done in March. Rooting hormone is used during the cutting planting process.

To overcome germination barriers of the identified taxa in the study area, hormone treatment is applied to 7 taxa, soaking in cold water is done for 4 taxa, fungicide treatment is applied to two taxa, and acid pre-treatment is done for one taxa. However, 12 taxa do not require any pre-treatment (Table 2).

When examining the production status in the last 5 years, it was determined that in 2018, 2,000,000 seedlings were produced, accounting for 15% of the total production. In 2019, 2,500,000 seedlings were produced, accounting for 19% of the total production. In the last 3 years, a total of 9,000,000 seedlings were produced, with each year producing 3,000,000 seedlings, accounting for 67% of the total production (Figure 2).

Figure 2. Seedling production in the studied nursery between 2018 and 2022

September 14-15, 2023, Naples, Italy

In terms of water consumption, which is one of the essential elements for ensuring sustainability in the study area, the plant taxa with a moderate level of water consumption are found to be the highest at 58%. They are followed by plant taxa with low/medium water consumption at 19%, low water consumption at 15%, high water consumption at 8%, and medium/high water consumption at 0% (Table 3; Figure 3).

Figure 3. The number of plant taxa based on water consumption levels

Based on the evaluations conducted regarding ecological tolerance (frost, heat, drought, salt, pollution, and wind), it has been determined that 92% of the plants identified in Diyarbakır Forest Nursery are tolerant to frost. However, only 69% of the plant taxa are tolerant to heat. It was found that 73% of the plants are tolerant to drought, 50% are tolerant to salt, 88% are tolerant to pollution, and 69% are tolerant to wind (Table 4).

*1 = low tolerance, 2 = moderate tolerance, and 3 = high tolerance

In Diyarbakır Forest Nursery, various cultural practices such as hoeing, transplanting, irrigation, weeding, fertilization, and repotting are carried out. Hoeing is performed for most plant taxa (11) starting in April and continuing every month until December. Transplanting is done in June for 9 plant taxa. Irrigation is carried out every two days for 17 plant taxa, while for 9 plant taxa, it is done every four days. Weeding is performed once a month for all plant taxa, starting in April and continuing until June. Fertilization begins in June and lasts until October, with animal manure being used once a month. Fertilization is applied in conjunction with irrigation, either in the early morning or late evening, to increase water retention capacity and permeability. Repotting is done in March and November for *Cupressus sempervirens* cv. 'Pyramidalis', *C. arizonica* L. 'Greene', *Pistacia vera* L., *Platanus orientalis* L., *Thuja orientalis* L., and *T. orientalis* cv. 'Aurea Nana', while for the other taxa, it is done in March (Table 5).

One of the biggest problems faced by the employees working in Diyarbakır Forest Nursery is that they have to do every job outside their own expertise. Therefore, they want to have a representative for each job category. Employees also face difficulties in reaching the nursery, so they state that if lodgings are provided at the nursery, both transportation problems will be solved, and they will have accommodation facilities.

The main problems related to the locations of forest nurseries include being far from the market, being far from raw materials, difficulty in finding qualified personnel, and various other issues. According to Alkan and Divrik (2019), it has been determined that forest nurseries face many problems related to their locations, such as being distant from the market, being far from raw materials, and the difficulty of finding qualified personnel. In a study conducted by Daşdemir (2017) in forest management offices, it was found that the main problems include a lack of technical, administrative, and labor status personnel to meet the needs, and there is insufficient personnel in proportion to the working area and workload.

In a survey conducted by Pak et al. (2021) among forest management chiefs and forest conservation officers in the Southeastern Anatolia Region of Turkey, it was found that the major problems were the "lack of qualified and experienced personnel" (90.1%), "low economic status of forest villagers in the region, which increases their dependency on the forest" (68.6%), and

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

"employees facing political pressure while performing their duties" (82.3%). In another survey conducted by Pak et al. (2022) on job descriptions in the Kahramanmaraş Forest Regional Directorate, 54.8% had negative opinions about employee shortages, while 42.9% had positive opinions. These studies reveal that there are problems with job descriptions both in forest nurseries and forest management offices.

According to the personnel surveyed in the study, Diyarbakır Forest Nursery holds a significant place in the market for both ornamental plants and forest tree seedlings in the Southeastern Anatolia Region, but they emphasize that they give more importance to the production of forest tree seedlings, and the majority of their sales consist of forest tree seedlings. Although Diyarbakır Forest Nursery does not have a market problem, a study by Divrik (2019) found that 60.8% of nursery managers were not at the desired level in terms of marketing. This difference may be due to the regional variability in the market conditions of forest nurseries.

It is believed that participating in different activities and conducting advertisements for the promotion of the forest nursery can greatly benefit tree seedling sales. Free distribution of seedlings to schools on special days like Forestry Week is done to instill a love for trees and forests in the public. In addition, promotional activities for seedlings are carried out by creating public service announcements. Such activities or promotions are considered important for raising awareness and development of the public. Similarly, in a study by Divrik (2019), 89.3% of nursery directorates agreed that pages on social media platforms like Facebook and Twitter contributed to promotion.

According to the information obtained from the nursery director, they mostly produce their own seedlings. In case of any need, they obtain the necessary seedlings from other nurseries affiliated with the directorate.

4. CONCLUSION and SUGGESTIONS

Like many other places in the world, the ornamental plant industry is also popular in Turkey. Therefore, both private and state enterprises engage in ornamental plant production on a regional basis. Given the potential to create alternative employment opportunities, these ornamental plant production enterprises should be valued and emphasized. To achieve this goal, it is crucial to identify the production potential as well as the demand and problems of these enterprises.

In this study, it has been revealed that the plant stock in Diyarbakır Forest Nursery primarily consists of 1+0-year-old bare-rooted ornamental plant seedlings, which are produced from seeds. However, the sale of forest trees is preferred more. It is necessary to conduct more comprehensive cultural practices and monitoring of the plant stock. The majority of the plant stock (58%) was found to have a moderate level of water consumption. Therefore, it is preferable to produce plant stock with low water consumption levels that are naturally distributed in the region and tolerant to ecological conditions. The production of tolerant plant stock will increase the demand for plants from the nursery in landscaping applications in the region and play an important role in the easier adaptation of plants after planting.

ABSTRACT

Open green spaces in and around the city are important places where people meet their needs such as resting and socializing. One of these important public spaces is parks. In this context, it is of great importance that the parks are accessible to everyone. In this study, Dokumapark in Antalya was examined in terms of the unrestricted movement of disadvantaged individuals in the park and their accessibility to various furniture. For this purpose, observation and detection method was used. Although the width of the walking paths in Dokumapark are in accordance with the standards, the inadequacy of the floor materials restricts the movements of the disadvantaged individuals. In addition, there are no tactile ground surfaces and walking lanes for visually impaired individuals on the roads in the park. There is a total of 219 parking spaces in the park, 6 of which are reserved for the disabled, but this does not comply with the rate specified in the parking regulation. The dimensions of the seating elements in the park are sufficient. There is not enough space for wheelchairs around the table. The heights of the garbage cans do not comply with the standard height dimensions. In addition, the locations of the furniture for the visually impaired are not specified with the necessary texture or color difference applications. For more effective use of Dokumapark by disadvantaged individuals, re-planning and design works should be carried out in the park by taking into account the results of the present study. Thus, it will improve the wellbeing of those who are less fortunate and their level of societal integration. In future studies, more comprehensive results can be obtained by conducting interviews with disadvantaged individuals in Dokumapark.

Keywords: Disadvantaged Individual, Dokumapark, Furniture, Accessibility.

1. INTRODUCTION

Parks are important spaces that provide various benefits to cities and their residents (Toomey et al., 2020). Considered as expansive green areas in densely urbanized regions, parks are among the most popular and frequently visited public spaces by users (Polko & Kimic, 2021). In addition to offering environmental and social services as well as recreational opportunities,

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

these areas also enhance the aesthetic appeal of urban environments (Konijnendijk et al., 2013; Nowak et al., 2018; Schnell et al., 2019). Furthermore, as parks are often viewed as the lungs of the city, they also support the structures in residential areas (Jim & Chen, 2006).

The term "disadvantaged" is comprehensive and flexible. In this study, it is considered to encompass elderly individuals, parents with baby strollers, pregnant women, visually and mobility impaired individuals, as well as wheelchair users. Planning and designing park areas with the ease of use for these individuals in mind is of utmost importance. This way, these individuals will be able to use these spaces easily during their leisure time and greatly enhance their social interaction.

Despite previous studies (Akgün Pişkin, 2021; Belkayalı & Güloğlu, 2019; Buğra Tekinalp & Birol Özerk, 2015; Çetişli-Korkmaz et al., 2021; Güngör, 2016; Güngör et al., 2016; Kurşun, 2014; Olgun & Yılmaz, 2014; Stanton-Chapman & Schmidt, 2018; Tarhuni, 2022) indicating that parks are not very suitable for the use of disabled individuals, the number of studies aimed at enabling these individuals to use parks seamlessly remains inadequate.

In this study, the aim is to assess the suitability of Antalya's Dokumapark for use by disadvantaged individuals.

2. MATERIAL and METHOD

In this research, Dokumapark located in the Antalya province of Turkey was chosen as the study area (Figure 1). The park is approximately 5 km away from the city center of Antalya. It was named Dokumapark in 2009 and was opened in 2015, covering an area of 238,000 square meters, which includes green spaces, a cafeteria, and sports facilities. There is a total of 116,000 square meters of green area in the study area. Dokumapark is considered one of the attraction centers of Antalya (Anonymous, 2023).

Figure 1. Location of study area

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

In this study, an observation and assessment method were utilized. Data related to the park entrance, walking trials, parking lots, as well as urban and social furnitures within the study area were collected and evaluated according to standards for individuals with disabilities. Additionally, the findings of the study were supported with photographs.

3. RESULTS and DISCUSSION

a. Park Entrances

The study area has a total of 5 entrance points, providing access from various directions. The area is enclosed by walls, and there are no vehicle entrances; only pedestrian entrances are available. The width measurements of the entrances are sufficient according to user density (Figure 2).

Figure 2. Dokumapark entrances

b. Walking trials

To ensure that disadvantaged individuals can move freely and without encountering any obstacles on the walking trials, there should be no obstructions along the path route. Unsuitable grates, irregularities, differences in elevation, etc., should all be avoided (Gökçe, 2012). Pedestrian path pavements should be slip-resistant and designed to facilitate movement. Elements such as steps and drain covers should not protrude, and there should be no sudden changes in levels. The trials should be continuous and at the same level (TSE, 1999).

According to the criteria specified in TS 12576 (1999), pedestrian pathways/sidewalks should have a minimum width of 150 cm to allow two wheelchairs to pass each other comfortably (UN, 2004). According to these standards, the widths of the walking trials within the study area are suitable for the use of disadvantaged groups (Figure 3).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

In the area, cobblestone and soil have been used as paving materials for the walking trials. The lighting fixtures, trash bins, directional signs, etc., along the trials do not have detectable surface elements or contrasting textures or colors, which can be a hazard for visually impaired individuals. Additionally, there are no arrangements in place on the walking trials within the park to provide route guidance for visually impaired individuals (Figure 3).

Figure 3. Some walking trials in Dokumapark

The path shown in Figure 4, which does not conform to the width standard and other criteria, poses restrictions on the use of individuals with baby strollers, visual impairments, and mobility impairments. In this context, considering the fact that removing obstacles increases communication between disabled and non-disabled individuals, it is necessary to design and plan accessible and usable systems for disabled individuals (Koramaz & Küçükali, 2021).

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 4. Improper walking trials in Dokumapark

c. Parking lots

According to the parking regulations (2022), it is mandatory that one out of every 10 parking spaces be designated for disabled individuals with an appropriate disabled marking. These spaces should be located closest to the entrances, exits, and elevators of public buildings, regional parking lots, and general parking lots. The long side of a single parking space should be at least 4.90 meters, and the short side should be a minimum of 3.50 meters (Presidential Legislation Information System, 2022).

In general parking lots, there should be a visible and easily readable disabled sign indicating that disabled individuals can park there. Additionally, directional signs leading disabled individuals to their parking spaces within the facility and a disabled parking symbol on the ground, wall, or suspended from the ceiling in open parking spaces should be installed. In closed parking facilities, road signs should be illuminated at night (ÖZİDA, 2011).

In the study lots, there is one open parking lots (Figure 5). Within this lots, there are a total of 219 parking spaces, of which 6 are designated for disabled individuals with appropriate disabled markings. This number does not conform to the ratio specified in the parking regulations. The parking spaces designated for disabled individuals are located close to the entrance gate. The night lighting in the parking lots is sufficient. Asphalt is used as the paving material for the parking lots, and parking spaces are delineated with lines. There are directional signs indicating the entrance and exit of the parking lots.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 5. Parking lot in Dokumapark

d. Urban furniture

Seating elements

According to the criteria of the United Nations (UN) in 2004, rest areas with seating benches should have a clear space of 1.2 meters next to them for wheelchairs (Figure 6a). The height of the bench from the ground should be 45 cm, and the height of the backrest should be 70 cm (Figure 6b). To allow access from all sides for wheelchairs, the height of tables should be between 75 and 90 cm, with a minimum depth of 60 cm under the table (Figure 6c).

Figure 6. Design of seating fronts (a), Height of sitting bench (b), Sizes of tables in resting areas (c) (BM, 2004)

Most of the seating units within the area are of sufficient size. However, there is insufficient space at the edges of the tables for wheelchairs (Figure 7).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 7. Seating elements in Dokumapark

Trash cans

Trash bins should be positioned along pedestrian sidewalks, at least 40 cm away from the curb, and at a height of 90-120 cm, in a way that does not obstruct pedestrian movement (TS 12576, 1999) (Figure 8).

Figure 8. Standard measures of trash bin (TS 12576, 1999)

The positioning of the trash bins within the study area, being located at the boundaries of the walking paths and fixed to the ground, is restrictive to user movement. Additionally, the heights of the trash bins do not conform to the standard height measurements specified in TS 12576 (1999) (Figure 9).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Figure 9. Trash bins in Dokumapark

Fountains

The water drinking areas of fountains should be approximately 90 cm in height. The appropriate height for wheelchair users is 85 cm, while for other users, it's approximately 95 cm (UN, 2004) (Figure 10).

Figure 10. Standard measures of fountain (BM, 2004)

The measurements of the fountains within the study area are not suitable for the use of disadvantaged individuals. For visually impaired individuals, there are no guiding lines or elements indicating the location of the fountain (Figure 11).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Figure 11. Fountains in Dokumapark

Lightnings

The height of lighting fixtures should be as follows: 3-4 meters for walking trials, 4.5-6 meters for streets, 7.5-9 meters for avenues, and 10-12 meters for main roads. In parks and gardens, low lighting fixtures should have a maximum height of 1 meter, and high lighting fixtures should have a maximum height of 2.4 meters (Kartay, 2009). According to TS 12576 (1999) criteria, the headroom clearance should be made at a height of 2.2 meters or higher (Figure 12).

Figure 12. Mounting height in walking trial (TS 12576, 1999)

There are lighting fixtures with different heights within Dokumapark. All of the lighting fixtures have height measurements above the headroom clearance (Figure 13).

Figure 13. Lighting fixtures in Dokumapark

e. Plant materials

There are various plant species along the walking paths within the study area. The plants along the paths are adequately positioned at a distance from the path. However, some plants' branches extend to the walking paths. Additionally, there are no barriers or protective measures around the plant elements along the walking paths. Some sections have protective elements that visually impaired individuals can feel, separating the walking path from the green areas, while others do not have such elements (Figure 14).

f. Social furniture

Cemil Meriç Library

The library has stairs at the entrance but lacks a ramp for disabled individuals. However, there is an elevator designed for disabled individuals. The dimensions of the stairs (620 cm x 30 cm x 20 cm) do not conform to standards. Additionally, there are no detectable surface applications at the entrances, and there are no non-slip strips on the edges of the steps. Furthermore, the design is not suitable due to the empty space at the height of the steps (Figure 15).

Masjid and toilet

There are no staircase or ramp applications at the entrances of the masjid and Toilet-Washbasin (Figure 26).

Figure 26. Masjid and toilet in Dokumapark

4. CONCLUSIONS and SUGGESTIONS

In conclusion, urban open and green spaces are important places within the city where people can meet various needs such as relaxation and socialization. Parks, in particular, are significant public spaces within this classification. In this context, it is crucial that parks are accessible to everyone. Regardless of age or physical condition, all individuals should be able to access these spaces and fulfill their socialization needs.

As a result of this study, it has been determined that individuals' movements in Dokumapark, Antalya are restricted due to some errors and deficiencies in the implementation, and access to various facilities within the park is also limited. Here are the key conclusions and recommendations:

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

- While the widths of the walking trials in Dokumapark are generally compliant with standards, the inappropriate paving materials restrict the movements of disadvantaged individuals. Moreover, there are no tactile-sensitive surfaces and walking lanes for visually impaired individuals on the park's trials. In areas with inappropriate materials, replacements should be made with suitable materials, and walking lanes that can be followed by visually impaired individuals should be created.
- The number of disabled parking spaces in Dokumapark does not comply with the parking regulation. Therefore, the number of designated parking spaces for disabled individuals should be increased.
- There is insufficient space for wheelchair users at the edges of the areas in Dokumapark. Therefore, areas should be created in seating areas where wheelchair users can also be comfortable.
- Trash cans in the study area are located along the walking paths and are fixed to the ground. This restricts the movement of users. The heights of the trash cans do not comply with the height dimensions specified in TS 12576 (1999). Urban equipment elements that do not comply with standards should be redesigned to make them suitable.
- Some of the plant elements along the walking trials extend their branches onto the trials. Especially in terms of posing a danger to visually impaired individuals, pruning and maintenance should be carried out regularly.
- There is an adequate number of directional signs in the study area.
- Non-compliant points in stairs and ramps at building entrances should be reorganized according to the standards, and protective curbs should be added to the ramps.
- To facilitate easy access for disabled individuals, the toilet, sink, and masjid in the study area should be arranged accordingly.
- There are no texture or color difference applications to indicate the locations of equipment for visually impaired individuals. In order to ensure easy access and recognition of urban and social furniture in Dokumapark, ground coverings should be designed with different textures and colors.

ABSTRACT

Cities are complex structures that include areas such as residential, open and green, public, commercial, etc., where people meet their social, cultural and economic needs. Squares are one of the most important public open spaces in the cities, as they are known as a focal point of urban identity. In many cities, however, squares are far from being an attractive focal point. The aim of this study is to examine the woody plants used in the three main squares of Döşemealtı, Kepez and Muratpaşa counties in the central districts of Antalya, and also to evaluate the furniture in the square in terms of competence, functionality and aesthetics. As a result of the study, the highest number of woody plant species were detected in Kepez urban square while the highest number of woody plants was found in the Döşemealtı urban square. The woody species used in the squares are mostly exotic species, angiosperms and tree-formed plants. In addition, the rates of deciduous or evergreen woody species used in the squares are virtually 50%. Chamaecyparis lawsoniana, Pinus brutia and Araucaria heterophylla species were determined in two of the three squares, while the other detected species were in only one square. Moreover, according to the scoring results on the basis of the determined criteria, the most suitable square was Cumhuriyet Square in the Muratpaşa county. All of the examined squares are in good condition in terms of both accessibility and socialization of people. In conclusion, in addition to the design criteria, the functional and aesthetic elements of the plants should be considered together in the plant design of the squares.

Keywords: Square, Plant Material, Landscape Design.

1. INTRODUCTION

Cities are complex structures that fulfill the social, cultural, and economic needs of individuals, encompassing various elements such as housing, open green spaces, public areas, and commercial zones. Among these elements, urban open spaces, particularly parks, play a vital role in defining a city's identity. In this regard, the concept of squares or public plazas is significant.

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Squares are open spaces typically located in city centers where individuals gather and engage in various activities such as meeting and socializing (Oktay, 2017). Usually surrounded by streets and buildings, squares serve as the focal point of a city and evoke a sense of pause in people. Squares are open spaces accessible to the entire community (Ender Altay et al., 2022). The relationship between the city and the square should be evaluated and regulated with a comprehensive perspective (Turgut, 2020). Squares are symbolic spaces for the city. In this respect, their designs being unique and providing clues about the history and culture of their location make squares more attractive.

The concept of squares, as one of the most important public spaces in urban open space classification, has been present from ancient times to the present day. Throughout history, squares have served as meeting places for city dwellers or visitors, places where they can take a break from the hustle and bustle of the city, relax and rest, come together, and share the events happening in the city. In short, squares have been multi-purpose spaces (Akman, 2020; Bayrakdar et al., 2022). The only constant feature of squares throughout history is their central location in the city as urban open spaces and their importance in shaping the city. On the other hand, 20th-century squares have undergone changes due to urban developments (Önder & Aklanoglu, 2002) and are generally open spaces with hard surfaces where activities such as resting, strolling, and gathering take place (Yıldızhan, 2018; Tezer et al., 2023).

The location of squares is closely related to the structural order of the city when viewed as a whole (Özdoğan, 2019). City squares are located in areas at the intersections of busy streets, surrounded by roads, and carry traces of the city's past (Demirel, 2008). When squares are considered as the courtyard of the city, they have the quality to meet some of individuals' daily needs, contribute to the cultural aspect, and fulfill the needs for relaxation and entertainment (Özdoğan, 2019). When looking at developed cities in many countries, it can be seen that squares have significant effects on urban identity. Indeed, prominent cities in developed countries are known and symbolized by their squares. Many of these squares also serve as urban open spaces that meet the recreational needs of city dwellers.

Plants play an important role in the landscape design of squares. The qualities that plants bring to the space support the perception of the square. In square design, plants should be selected considering the climate, sunlight, and rainfall of the location (Başaran et al., 2020; Özer et al., 2020). The use of single trees, rows of trees, tree clusters, combinations of several trees coming together, and various other combinations of plant materials in squares create attractive spaces in terms of form and function (Erduran Nemutlu et al., 2021).

It is noteworthy that most of the studies conducted on squares have focused on urban furniture. Recently, there have been some studies on the plant elements of squares in different regions (Şenel, 2013; Erduran Nemutlu, 2014; Torlak Güneri & Yerli, 2019; Başaran et al., 2020; Erduran Nemutlu et al., 2021; Pashaei Kamali, 2021). In this study, the main squares of Döşemealtı, Kepez, and Muratpaşa districts in Antalya province were examined and compared in terms of the plant materials used.

2. MATERIAL and METHOD

This study was conducted in the main squares of Kepez, Muratpaşa, and Döşemealtı districts in Antalya, Turkey (Figure 1). The sizes of the studied squares and the plant materials used in them were identified. The research employed on-site observation and assessment methods.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Within the scope of the study, woody plant species, including the number, variety, location of use, and manner of use of trees and shrubs used in the squares, were evaluated. Additionally, the squares were assessed based on criteria determined for general use, using a scoring method.

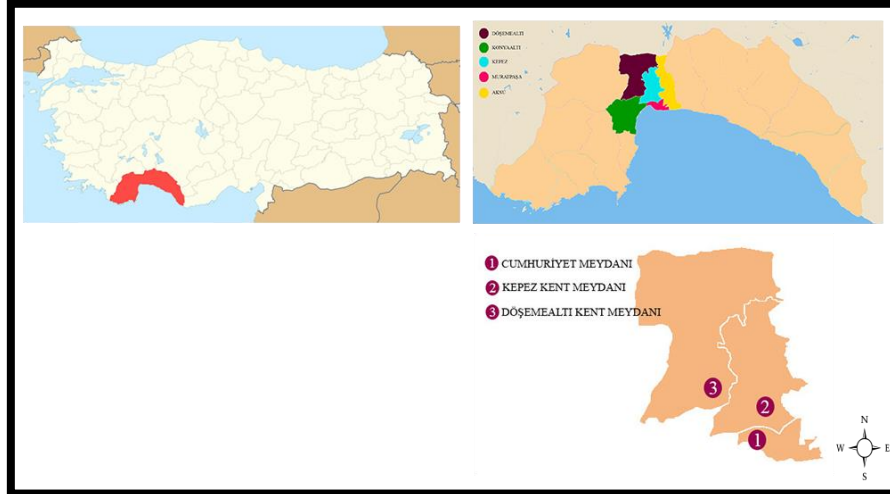

Figure 1. Location of study areas

Cumhuriyet Square is located on Cumhuriyet Avenue in Muratpaşa District of Antalya Province. To the north, it is bordered by Şehit Binbaşı Cengiz Toytunç Avenue and the Antalya Governorship, to the south by the Kaleiçi District, and to the west and east by various shops and businesses. Cumhuriyet Square underwent a significant transformation in 2008, resulting in a total area of 11,500 square meters. Kepez Kent Square, on the other hand, is situated on Seyhan Avenue next to the Turgut Özal Sports Hall and covers a sprawling area of 42,000 square meters. It holds the distinction of being the largest square in Antalya, completed in 2017. Döşemealtı Kent Square, completed in 2017, is the first square of Döşemealtı. It spans an area of 16,500 square meters. (Figure 2).

Figure 2. Locations of plant materials in Cumhuriyet (upper left side), Döşemealtı (upper right side) and Kepez (bottom side) squares

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

3. RESULTS and DISCUSSION

Plants, which are vital sources of oxygen for our planet and cities, offer numerous ecosystem services. Their characteristics such as form, texture, seasonal colors, and leaf shedding, along with temporal changes, contribute to the attractiveness of spaces and create more dynamic environments from a functional perspective (Sarı & Karaşah, 2018). The presence of plant materials not only enhances the aesthetic appeal of a design but also provides functional contributions. It prevents spaces from appearing monotonous and adds value to the environment.

a. Döşemealtı urban square

A total of 766 woody plant specimens belonging to 8 species were identified in Döşemealtı Urban Square (Table 1; Figure 3). The most frequently used woody plant species in Döşemealtı Urban square was *Euonymus japonicus* Thunb., commonly known as "Taflan." It is observed that deciduous woody plants are not extensively used in the square. However, since squares are large open spaces, it is important to incorporate shade-providing tree species in appropriate locations.

Table 1. Plant materials in Döşemealtı urban square

Latin Name	Number
<i>Araucaria heterophylla</i> (Salisb.) Franco	8
<i>Ceiba speciosa</i> (A.St.-Hil.) Ravenna	18
<i>Chamaecyparis lawsoniana</i> (A.Murray bis) Parl	134
<i>Euonymus japonicus</i> Thunb.	565
<i>Hibiscus syriacus</i> L.	24
<i>Olea europaea</i> L.	3
<i>Pinus brutia</i> Ten.	4
<i>Washingtonia robusta</i> H. Wendl.	10

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 3. Woody plants in Döşemealtı urban square

b. Cumhuriyet square

A total of 129 woody plant specimens belonging to 7 species were identified in Cumhuriyet Square (Table 2; Figure 4). The most frequently used woody plant species in Cumhuriyet Square was *Trachycarpus fortunei* (hook.) H.Wendl., commonly known as "Telli palmiye." The abundance of shade-providing and evergreen trees in the square indicates the consideration of both aesthetic and functional criteria in the design. While woody plants used in the square are generally arranged in rows, the *T. fortunei* species is clustered in groups. *Cupressus sempervirens* L. and *Celtis australis* L. woody plant species are used for surrounding the square.

Table 2. Plant materials in Cumhuriyet square

Latin Name	Number
<i>Celtis australis</i> L.	12
<i>Cupressus sempervirens</i> L.	15
<i>Cycas revoluta</i> Thunb.	16
<i>Ficus microcarpa</i> Vahl	5
<i>Ficus microcarpa</i> cv. "Bonsai"	27
<i>Pinus brutia</i> Ten.	10
<i>Pittosporum tobira</i> "Nana"	5
<i>Trachycarpus fortunei</i> (Hook.) H.Wendl.	44

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 4. Woody plants in Cumhuriyet square

c. Kepez urban square

A total of 397 plants belonging to 19 species were identified in Kepez Urban Square (Table 3; Figure 5). The most frequently used woody plant species in this square was *Buxus sempervirens* L., commonly known as "şimşir." The dense use of this evergreen species suggests attention to aesthetics. Other frequently used species in the square were *Rosmarinus officinalis* L., *Chamaecyparis lawsoniana* (A. Murray bis) Parl and *Forsythia x intermedia* Zabel. It is worth noting that some of the plants in the square are arranged in rows, some provide shade to seating elements, while others are randomly placed and appear to be poorly maintained.

Table 3. Plant material in Kepez urban square

Latin Name	Number
<i>Aesculus hippocastanum</i> L.	3
<i>Araucaria heterophylla</i> (Salisb.) Franco	1
<i>Buxus sempervirens</i> L.	65
<i>Cercis siliquastrum</i> L.	5
<i>Chamaecyparis lawsoniana</i> (A.Murray bis) Parl	44
<i>Cinnamomum camphora</i> (L.) J. Presl	8
<i>Elaeagnus angustifolia</i> L.	1
<i>Eugenia uniflora</i> L.	24
<i>Ficus microcarpa</i> Vahl	15
<i>Forsythia x intermedia</i> Zabel	40
<i>Fraxinus angustifolia</i> Vahl	19
<i>Liquidambar styraciflua</i> L.	4
<i>Liriodendron tulipifera</i> L.	14
<i>Morus alba</i> L.	1
<i>Olea europaea</i> L.	3
<i>Populus tremula</i> L.	24
<i>Prunus cerasifera</i> Ehrh.	35
<i>Rhamnus alaternus</i> L.	31
<i>Rosmarinus officinalis</i> L.	60

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 5. Woody plants in Kepez urban square

d. Furniture in squares

Furnishing elements used in open spaces are essential components that enhance both the aesthetics and functionality of spaces, making life easier for individuals (Özgeriş, 2018). Since squares are one of the most heavily used public spaces, well-designed and properly placed furnishing elements contribute to enhancing the attractiveness of the square. Elements like pergolas, gazebos, benches, trash bins, and others play a significant role in creating different effects in square designs. To consider a square successfully designed, it needs to meet certain criteria, with image and identity being one of the primary factors. A square should incorporate clues specific to the city it belongs to, include elements that reflect the city, and create an atmosphere that represents the unique character of the city.

When evaluating the squares in this study based on the established criteria, Cumhuriyet Square received the highest score. Cumhuriyet Square includes all water features, while Döşemealtı and Kepez squares only have fountains or ornamental pools. All three squares provide suitable conditions for people to socialize. Flexibility in design is also important for squares to adapt to changing weather conditions and events. This can be achieved through features like mobile stages, portable tables and chairs, umbrellas, and having storage on-site for these materials.

However, none of the squares examined in this study had a storage area with this function. Regarding accessibility, squares should be easily reachable on foot, have narrow streets surrounding them, well-placed pedestrian crossings, synchronized traffic lights near them, and slow-moving traffic. In this context, all three squares studied were found to be accessible (Table 4; Figure 6).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Table 4. Scoring of the studied squares based on criteria

Criteria	Characteristics	Scoring (1-2-3)		
		Cumhuriyet	Döşemealtı	Kepez
Transportation	Connected to multiple boulevards or streets (within 0-100 meters)	3	2	3
	Public transportation passing by within 0-15 minutes frequency	3	3	3
	Density of private vehicle parking areas in the vicinity (200 meters and beyond)	3	1	2
	Size and Density 500 square meters or larger in size	3	3	3
Büyüklik ve Yoğunluk	Capacity for 250 people or more	3	3	3
	If the number of architectural elements in the vicinity is 2 or less (within 0-100 meters)	3	2	1
	If there are trees and shrubs	3	3	3
Plant Element	If there are shrub groups and clusters	2	3	3
	Y If there are ground cover and grass areas	2	3	2
	If there is a sea or river	2	0	0
Water Element	If there is a pool or ornamental fountain	3	3	3
	If there is a fountain or any other water element	2	0	0
	If there is an amphitheater or sculpture	3	1	0
Urban furniture	If there are pergolas, gazebos, benches, trash bins, etc.	2	2	3
	If there are lighting elements	3	3	3
Connection with Green Areas	If it is within a green belt	1	1	1
	If it is within a greenway	1	1	1
	If it is within urban parks	2	2	2
Land Uses	In proximity to public and cultural areas (within 0-500 meters)	3	2	3
	In proximity to commercial areas (within 0-500 meters)	3	3	3
	In proximity to residential and agricultural areas (within 0-500 meters)	1	2	3
Total		51	43	45

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Figure 6. Cafe, pergola, seating and lighting elements in Kepez urban square (a-e), Cafe, trash bin, seating elements in Döşemealtı urban square (f-i) and seating and lighting elements, statue and pool in Cumhuriyet square (i-k)

4. CONCLUSIONS and SUGGESTIONS

The main squares in the districts of Döşemealtı, Kepez, and Cumhuriyet in Antalya province exhibit a diversity of plant materials. The presence of a variety of plant species and the use of many different types of plants together make the squares richer and more perceptible. Furthermore, the combination of shade-providing tree species with pergolas in seating areas is beneficial both aesthetically and functionally.

Permeability in flooring materials is an essential criterion in terms of climate sensitivity. Therefore, the flooring materials used in squares should be designed with this consideration in mind, aiming to create green paths connected to the squares. The existence of green paths is crucial for pedestrian safety and climate sensitivity.

The presence of surrounding trees in the squares acts as a limiting factor in creating a sense of space while also providing shade. Cafes and cafeterias in the squares are considered as spaces for socializing and add meaning to the square. Additionally, the presence of a water element in the squares creates a refreshing effect required by the regional climate. In Kepez and Döşemealtı squares, addressing the absence of these elements will enhance their desired characteristics.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

In the planning and design of squares falling under the category of urban open spaces, planning and design criteria should be considered. In this context, the most crucial point to bear in mind is that squares are public spaces and should respond to public activities. They need to be functionally adequate while being designed with aesthetic considerations in mind.

ABSTRACT

Even though Türkiye has more protected areas than ever, one of the ongoing issues with national parks is still the absence of inventory. It is challenging for national parks to make effective management and planning decisions as a result of this flaw. National parks, however, are among the most popular and successful spaces in Türkiye for addressing people's demands for recreation. In this study, Kızıldağ National Park located in Şarkıkaraağaç district of Isparta province was examined and evaluations were made in terms of daily activities and spatial competence. For this purpose, the spatial competencies of recreational activity areas, the existing furniture, infrastructure adequacy and the suitability of their recreational use were examined by using the observation and detection method. According to the data between 2018-2022, the average number of visitors to Kızıldağ National Park was 55539. It was found out in the national park that the area used for picnics was insufficient, there was no uniform distribution of playground, trash cans, toilets, or lighting furniture in the area, the furniture was made of materials unaesthetically and unsuitable, there was no parking area, and the accommodation units were large and occupied an excessive space. The picnic area should be removed from its current location and designed together with the parking lot in a different location. Both renewing the furniture with aesthetically pleasing and useful materials and ensuring their uniform distribution in the park are important. Re-planning the Kızıldağ National Park with a sustainable approach will ensure more effective use of the area by choosing an area suitable for recreational activities that will contribute to the needs of visitors and the protection of the area.

Keywords: National Park, Recreation, Furniture, Space.

1. INTRODUCTION

The unplanned growth initiated by the increasing world population, industrialization, urbanization, and the reckless use of natural and cultural resources have caused irreversible damage to the environment. Throughout history, humanity has endeavored to find solutions to these problems, leading to the emergence of the concept of nature conservation (Kılıç & Kervankıran, 2019). Nature conservation is defined as the protection of plant and animal species existing in nature, along with their natural habitats, under specific conditions, for the guarantee of human life (Yücel, 2005).

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium **September 14-15, 2023, Naples, Italy**

Efforts to develop various conservation methods and tools for the preservation of natural and cultural resources are increasing worldwide. At the international level, one of the most advanced and widely accepted efforts is the establishment of protected areas (Kurdođlu, 2007). Many countries have designated natural, cultural, and historical sites as protected areas with the aim of preserving their existing characteristics for sustainable use (Yücel & Babuř, 2005). These protected areas play a vital role in national and international conservation efforts. Many areas rich in biological diversity and natural-cultural values are now designated as national parks, nature reserves, and other protected areas, serving the conservation of biological and cultural diversity (Gümüř et al., 2010).

Within areas of significant value, with the aim of preserving endangered species and natural-cultural values in the long term and passing them on to future generations, the concept of "National Parks" was introduced (Yücel & Babuř, 2005). National Parks are defined as natural areas with rare natural and cultural resource values, offering protection, relaxation, and tourism opportunities from both scientific and aesthetic perspectives (Anonim, 2023a).

In Turkey, the concept of national parks was first introduced through the Forest Law in 1956, prior to the enactment of the National Parks Law in 1983. National parks were designated under this law until 1983 (Koç & Soykan, 2020). However, it is noted that, compared to the United States and European countries, recent years have seen increased efforts in Turkey regarding national parks, and conservation activities are still carried out within the framework of traditional planning (Bayar & Göktuđ, 2021). Currently, there are 48 national parks in Turkey, covering a total area of 911,000 hectares (Anonim, 2023b).

National parks in Turkey have gained increasing importance and attract numerous visitors today (řahbaz & Altınay, 2015). These parks offer various recreational activities such as nature walks, camping, rock climbing, canyon crossings, water sports, cycling, bird watching, mountaineering, photography, picnicking, flora-fauna observation, and fishing (řahbaz & Altınay, 2015).

While several studies have been conducted on the recreational values and uses of national parks in Turkey, including examinations of the recreational values of Kastamonu-Bartın Küre Mountains National Park (Öztürk, 2005), the recreational use and conservation of Yozgat řamlık National Park (Ergen, 2005), visitor-related issues in Antalya Olimpos-Beydađları Coastal National Park's day-use recreational areas (Uzun et al., 2014), determining the quality of recreational experiences in Ilgaz Mountains National Park (Göktuđ & Yenilmez Arpa, 2015), and factors affecting recreational satisfaction of users in Aksaray Altındere Valley National Park (Aksu et al., 2017), there has been no study to date that examines day-use activities and spatial adequacy in Kızıldađ National Park. This study aims to identify day-use activities conducted in designated outdoor recreation areas within Kızıldađ National Park, analyze the spatial adequacy of recreational areas, assess their deficiencies, and contribute to landscape projects in the national park based on the study results.

2. MATERIAL AND METHOD

The Kızıldađ National Park, located within the boundaries of Isparta province, was declared a National Park on May 9, 1969, with an initial area of 2,316 hectares, with the aim of preserving and passing on its biological (flora, fauna, ecological structure), geomorphological, geological, cultural, landscape, and recreational resource values to future generations. In 1993, the national

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

park's area was increased to 59,400 hectares, and in 2018, it was further expanded to 80,200.42 hectares (Anonymous, 2023c).

Kızıldağ National Park is situated in the Western Mediterranean Region, within the administrative boundaries of Isparta province, including the districts of Şarkikaraağaç, Yenişarbademli, Aksu, Eğirdir, and Sütçüler (Figure 1). Located in the northern and western parts of Lake Beyşehir, Kızıldağ National Park lies between the north latitudes of $37^{\circ} 28' 30''$ - $38^{\circ} 31' 21''$ and the east longitudes of $31^{\circ} 31' 37''$ - $31^{\circ} 30' 12''$. To the north of the national park are the Şarkikaraağaç district center, Beyköy, Şarkikaraağaç-Beyşehir asphalt road, to the east is Lake Beyşehir, to the southeast are the northwestern parts of Gölyaka and Yenişarbademli districts, to the south are the villages of Aşağıkartoz, Aşağıyaylabel, and Yukarıyaylabel within the boundaries of Sütçüler district, to the southwest are Eldere Village, Aksu Yaka Canyon, Aksu district, Sarıdris, Bağacık Villages, and Anamas Plateau (Anonymous, 2023c).

Figure 1. Location of Kızıldağ National Park

In Turkey, National Parks are managed by the Ministry of Agriculture and Forestry, Directorate General for Nature Conservation and National Parks, both at the central and provincial levels, with the principle of conservation-use balance, following the preparation of Long-Term Development Plans (UDGP) at a scale of 1/25,000. These plans determine the absolute protection, sensitive protection, sustainable use, and controlled use zones and activities, guided by an analytical study, synthesis, and planning approach.

Within the boundaries of the study area, the spatial adequacy of day-use recreational activity areas designated for open-air recreation activities has been determined using observation and assessment methods. This assessment includes the examination of existing infrastructure elements, spatial adequacy, and the suitability of day-use recreational activities for the area. The data obtained from these assessments have been supplemented with photographs taken in the field.

3. RESULTS and DISCUSSION

The day-use area of Kızıldağ National Park, located within the boundaries of Şarkikaraağaç district in Isparta province, is approximately 7 km away from the town center. Within the day-use area, there are various facilities and amenities, including cottages (bungalows), tent camping areas, a countryside restaurant, a traditional Turkish tent restaurant, a children's playground, an oven, a buffet, sales units, a mosque, toilets, shower cabins, lighting elements, information, warning, and directional signs, walking paths, an entrance control unit, water fountains, trash bins, picnic units (picnic tables, barbecue grills), and shading elements (pergolas) (Table 1; Figure 2).

Table 1. Furniture in Kızıldağ National Park

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 2. Daily use area in Kızıldağ National Park

Access to the National Park area from the town center of Şarkikaraağaç is provided via an asphalt road, and visitors are required to pay an entrance fee for admission. There is an entrance control unit with an area of 5 m² made of wood, and an entrance gate covering the road section (Figure 3).

Figure 3. Entrance control unit

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

The day-use and camping area is accessible from the entrance control unit via an approximately 3.5 km asphalt road. On the left (south) side of the asphalt road, connected to the road circulation within the day-use area, there is an area of approximately 2000 m² that is used as a tent camping area. Due to the sloping topography of the tent camping area, 75 tent sites have been created using a terrace method. The tent camping area includes an electrical panel, and electrical outlets are provided on the wall surfaces of the established terraces for visitors' convenience. For visitors in the camping area, two wooden-clad container cabins have been placed, each consisting of a toilet and shower section, measuring 2.5 * 2.5 m. In the camping area where making fires for picnicking purposes is not allowed, picnic units (picnic tables) are available for visitors to use (Figure 4).

Figure 4. Camping area with tent

There is currently no designated parking area for day-use activities and accommodation purposes for visiting vehicles. As a result, vehicles are parked irregularly along the roadside, restricting the use of the area (Figure 5).

Figure 5. Irregular car parking

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Within the area, there are five duplex-style cottages (bungalows) located in the same vicinity as the countryside restaurant. Each bungalow, along with its terrace, covers an area of approximately 90 m² and is constructed with a wooden cladding on a reinforced concrete base. In a study conducted by Korkmaz (2001), it was mentioned that in 1987, five bungalows, common facilities, a restaurant-bakery, toilets, and other infrastructure facilities were completed in Kızıldağ National Park. The connection paths between the cottages are paved with slate and bordered by wooden railings (Figure 6).

Figure 6. Bungalows

Within the area, there are two countryside restaurants that cater to visitors' dining needs, including a countryside restaurant and a traditional Turkish tent (bristle tent) restaurant. The countryside restaurant, located adjacent to the cottages, has a closed area of 170 m², and its terrace, extended with wooden materials, covers an approximate area of 230 m², where meal and picnic tables are provided. The two-story building also includes a lower floor with an area of approximately 80 m², housing a stone oven and an annex section consisting of three rooms. The traditional Turkish tent restaurant is situated to the northeast of the countryside restaurant, approximately 20 meters higher in elevation and 250 meters further away. The bristle tent restaurant has a closed area of 65 m², including a kitchen section and seating groups. The open area, partially paved with cobblestones, covers 3,000 m² and features picnic tables, five wooden pergolas, and a panoramic photo shoot area with a scenic view. In the same open area, there is a combined 230 m² reinforced concrete facility (toilet, bathroom), and visitors park their vehicles in this open area (Figure 7).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 7. Bristle tent, restaurant and photo shooting area

There are two children's play areas within the vicinity, one located in the lower part of the countryside restaurant (40 m²) and the other at the entrance of the traditional Turkish tent restaurant area (25 m²). These play areas feature metal-plastic and wooden play equipment (Figure 8). Öztürk & Gül (2020) emphasized the use of natural play elements (wood) and materials that promote physical and mental development when planning children's play areas.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 8. Playgrounds

There is a snack bar with a total area of 30 m² (indoor) and 15 m² (outdoor) that offers products catering to visitors' needs. Additionally, there are four portable sales stands, each with a total area of 24 m² (indoor) and 26 m² (outdoor), made of wooden materials for selling souvenirs. The concrete mosque building within the area has been constructed with wooden cladding, covering an area of 60 m². It includes toilet and ablution facilities at the rear and a wooden minaret at the front (Figure 9).

Figure 9. Buffet, portable sale stands and masjid

There is one concrete restroom facility and six container restrooms within the area, covering a total area of 35 m². The concrete restroom and three of the container restrooms also include shower facilities (Figure 10). Restrooms with shower facilities are located within the tent camping area and in close proximity.

Figure 10. Toilet and shower units

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Within the area, there are fountains provided for visitors' drinking and utility water needs (Figure 11). When planning picnic areas in natural settings, Akten & Gül (2014) recommended an optimal range of 150-250 people per hectare (30-50 picnic units). However, it is anticipated that these picnic units should be positioned to serve an optimal range of 50-100 people per hectare (10-20 picnic units) while considering the balance between conservation and use. Additionally, the same authors suggested that for every 4 or 5 picnic units, there should be 1 fountain and 1 trash can.

Figure 11. Fountains

One of the primary reasons people prefer national parks is the availability of suitable picnic areas and the opportunity to connect with nature. Schroeder (1982) emphasized that natural green spaces and aesthetically appealing environments are particularly attractive to urban residents. For this reason, the national park includes a large picnic area covering 6,000 m² (0.6 hectares) where picnic units are located. There are 50 fire pits in the picnic area (Figure 12).

Figure 12. Picnic units

Throughout the area, there are various informational, warning, and directional signs with different designs, materials, and sizes (Figure 13). The diversity of signs in the area creates visual clutter and can be considered as visual pollution.

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

Figure 13. Information, warning and orientation signs

One of the infrastructure elements, lighting fixtures, has been irregularly placed in various designs and sizes within the area. This irregular placement of lighting fixtures within the protected area creates an aesthetically negative appearance in the specially designated day-use and accommodation areas. Additionally, there is aerial cable clutter within the area (Figure 14).

Figure 14. Lighting elements

At certain points within the area, there are metal trash bins (containers) in groups of various sizes and colors; however, they do not exhibit a homogeneous distribution within the area (Figure 15).

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 15. Trash cans

The hiking trails within the day-use area provide access to the area's internal equipment (Figure 16). It is paved with slate stone as a building material and is bordered by wooden railings in some places. Stairs and steps are used in sloping areas. Due to the sloping topography of the area, the inclusion of steps in some hiking trails and the use of slate stone as the pavement material may not be suitable for disabled visitors.

Figure 16. Walking trails

Existing forest roads within the area are used as nature hiking trails due to their high landscape value and panoramic views (Figure 17). The hiking trails, named Lake, Mountain, and Cedar routes, have lengths of 9.2 km, 6.5 km, and 3 km, respectively, and are heavily used by visitors. Direction and informational signs are located along the routes of the nature hiking trails.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 17. Trekking routes

According to the visitor data obtained from the Directorate of Nature Conservation and National Parks Isparta Branch for Kızıldağ National Park for the years 2018-2022, the annual average number of visitors was determined to be 55,539 people (Figure 18). On March 11, 2020, the World Health Organization (WHO) declared COVID-19 a pandemic (Yücedağ & Çetin, 2020). To mitigate the impact of the pandemic and slow its spread, various measures such as curfews, quarantines, and isolation processes were implemented worldwide at different times (Bozkurt, 2020). Therefore, Kızıldağ National Park experienced a decrease in the number of visitors in 2021-2022 due to these measures.

Figure 18. The numbers of visitor in Kızıldağ National Park between 2018 and 2022

4. CONCLUSION and SUGGESTIONS

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium **September 14-15, 2023, Naples, Italy**

Kızıldağ National Park, one of the important national parks in Isparta province, Turkey, offers opportunities for outdoor recreational activities with its pristine forest areas and natural landscape beauty. Kızıldağ National Park is predominantly preferred by the local people for picnicking in the daytime. In addition to picnicking, activities such as hiking, enjoying the scenery, taking photographs, and camping tourism are carried out in the area. With various recreational activities available within the national park, the area has high visitor potential.

One of the key factors that affect the recreational potential and quality of a national park is the design of infrastructure elements, which should be in harmony with the natural characteristics of the area. These infrastructure elements should be well-maintained, clean, aesthetic, ergonomic, functional, accessible to people with disabilities, and compatible with other facilities within the park.

Based on the study conducted in Kızıldağ National Park, the following recommendations have been made:

- During the summer months when there is heavy usage by the public, the insufficient parking and picnic area lead to visual and noise pollution. Therefore, it is recommended to designate a suitable area near the entrance control unit for parking and picnic area expansion.
- It is suggested that the existing day-use area be used solely for accommodation and that internal shuttle services be provided for visitors.
- To ensure the conservation and sustainability of the existing natural resources, it is advised to use appropriate natural materials and aesthetic infrastructure elements in the park's design.
- The lighting elements within the park should have a consistent visual style and be uniformly distributed. Existing seating groups should undergo maintenance, replacement, or addition, and their numbers should be increased.
- Information, direction, and warning signs within the park should be designed in the right locations and with appropriate materials.
- Overhead power lines in the park, which disrupt the aesthetic and landscape integrity, should be buried underground.
- Trash bins within the park should be designed using suitable natural materials and should be evenly distributed in the area.
- Existing children's play areas, which are currently distant from the picnic area, should be reorganized to be closer to picnic units and have adequate space.
- Water fountains should be arranged within easy reach of visitors, and water sources should be increased.
- It is recommended to place single-story accommodation units with a smaller footprint, in compliance with legal regulations, instead of the existing duplex bungalows, which occupy excessive space.

In conclusion, national parks play a crucial role in meeting the recreational needs in Turkey. To make Kızıldağ National Park more suitable for recreational activities while preserving its

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

natural resources, landscape design and implementation studies should be conducted, considering resource conservation, usage, functionality, and visitor expectations.

ABSTRACT

Urbanization has dramatically increased both in Türkiye and around the world in recent years. This increase caused to serious health issues, particularly for urban areas. Spending time in open green spaces in or around the city is one method for overcoming these health issues. One of the city's open green spaces is promenade. Due to their natural resources, these spaces have a positive impact on the people. In this study, it was aimed to examine the Ayazmana, Gökçay and Milas Promenade areas located in the city of Isparta in terms of their recreational uses and to evaluate their shortcomings. For this purpose, the observation and detection method were used in the study areas. In order to reveal the current state of the study areas and to provide a basis for the evaluations, a SWOT analysis of the areas was performed. 16, 18 and 15 different furniture were identified in the promenades of Ayazmana, Gökçay and Milas, respectively. It was revealed that the Gökçay promenade had more furniture than other examined areas, and that they are more well-maintained and adequate. Periodic maintenance works should be carried out in terms of the functionality and sustainable use of the existing furniture in the promenades. Intensive use of furniture by the urban people causes their wearing and damaging, and various vandalism acts. In order to prevent such harm, the public should be informed. In addition, a total of 21 broad-leaved and 6 coniferous species were determined in the plant species inventory in the examined areas. Including plant species with high aesthetic value and plant diversity in future plant design projects for these promenades will contribute to their recreational values. In conclusion, a novel approach to the planning and management of these promenades needs to be put into practice.

Keywords: Promenade, Recreation, Isparta, Open-Green Area.

1. INTRODUCTION

Urbanization is the process that emerged as people abandoned a nomadic lifestyle and embraced settled living, leading to the growth of cities and the formation of today's urban areas. Urbanization is a population accumulation process that creates organization, occupations, and specialization, leading to changes in human behavior and relationships, largely driven by industrial and economic development (Keleş, 2002).

Urbanization offers some social and cultural benefits to individuals but also imposes the necessity of living in an artificial and unhealthy environment (Önder & Polat, 2012). The

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

negative urban living conditions, such as intense work schedules, population density, noise, environmental pollution, artificial human relationships, etc., can lead to physical and emotional strain on people (Jitaru et al., 2012). Due to these challenges, urban residents often feel the need for nature. One of the spaces that fulfill this need in cities is open green spaces. Open green spaces not only satisfy the urban population's need for nature but also improve overall living conditions by addressing various challenges (Yücedağ et al., 2021).

Apart from architectural structures within urban areas, the spaces, green areas, and water elements that are found in cities are referred to as urban open green spaces. These spaces play roles in controlling urban development, creating unity and separation, providing aesthetics, ecology, economy, and recreational contributions to cities (Çelikyay, 2017). Urban open green spaces are used by many people daily regardless of their demographic characteristics and socio-economic status. They improve the quality of life both physically and psychologically (Abbasi et al., 2016), help balance the disrupted relationship between humans and nature, and enhance urban living conditions (Gül & Küçük, 2001). They also meet the recreation needs of urban residents for free and are managed by local authorities. Urban open green spaces can be categorized as active and passive. Active urban open green spaces include park areas, children's playgrounds, sports areas, Promenades, while passive urban open green spaces encompass medians, cemeteries, landscaped areas, and forested areas (Önen, 2015).

According to the Turkish Language Association (TDK, 2023), "mesire" refers to places suitable for walking, picnicking, and "mesirelik" refers to places suitable for leisure and picnicking. According to the Mesire Area Implementation Communiqué (Anonim, 2015), a mesire area is a forest-regime area designated for use with the necessary structures, facilities, and furniture to meet various relaxation, entertainment, and sports needs of society, contribute to the beauty of the country, and provide opportunities for tourism activities. The term "mesire" carries the same meaning as the word "recreation" and is used to describe areas where outdoor recreational activities take place (Kuş Şahin & Önder, 2021).

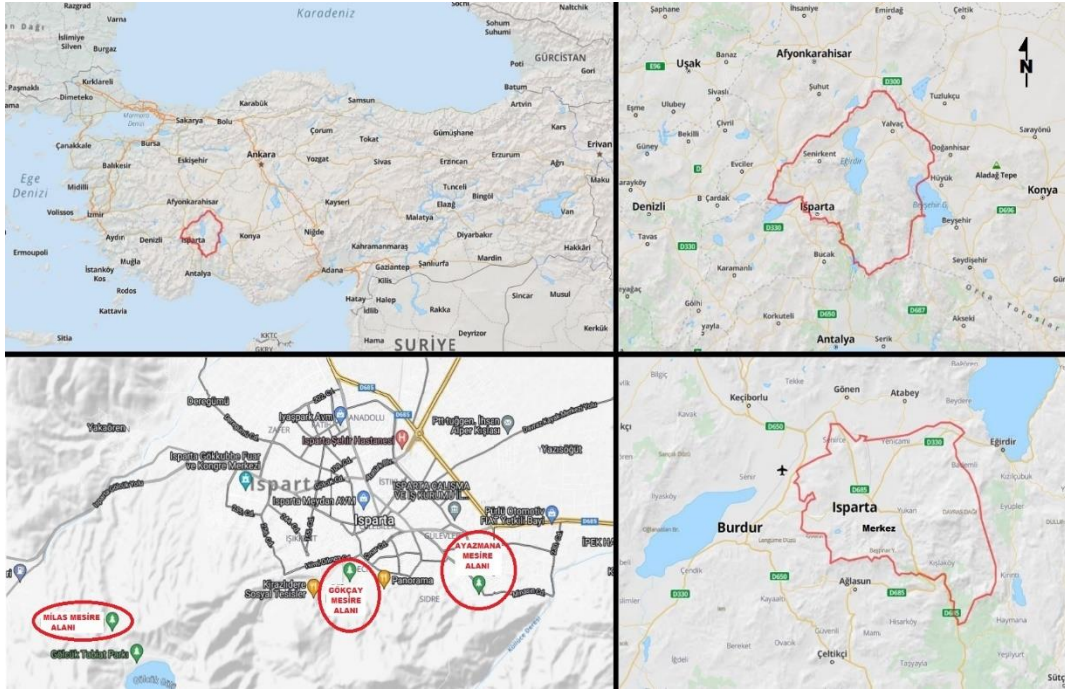

Recreational activities, which aim to enhance the quality of life and are voluntarily performed by individuals to refresh themselves physically and mentally, have become a necessity in human life (Köse & Kul, 2020). Outdoor recreation refers to activities carried out in natural or green areas where people can access nature beyond their working and essential needs (Türkmen et al., 2013). Urban open green spaces serve as venues for these recreational activities and help individuals balance their urban lifestyle with a connection to nature (Polat & Önder, 2004). Outdoor recreation activities can be both active and passive (Öztürk, 2018).

In Turkey, several studies have been conducted on visitors' recreational preferences and the recreational potential of mesire areas in various regions, including Beynam in Ankara-Bala district (Kaya & Yılmaz, 2013), Ekşisu in Erzincan-Merkez district (Yalçınayavuz & Yılmaz, 2016), Kepez Kent Ormanı in Antalya-Kepez district (Kuş Şahin & Önder, 2021), Harbiye (Daphne) Şelalesi in Hatay-Harbiye district (Yiğit, 2021), and Orduzu-Pınarbaşı in Malatya-Battalgazi district (Tapan, 2022). These studies aimed to determine visitors' recreational use patterns and preferences, as well as the recreational potential of these areas. However, no study has been conducted to evaluate the recreational use of Ayazmana, Gökçay, and Milas mesire areas in Isparta city center. Therefore, this study aims to examine these mesire areas in terms of recreational use, assess their deficiencies, and contribute to future landscape planning efforts in these areas.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

2. MATERIAL and METHOD

The study area includes the Ayazmana, Gökçay, and Milas Promenades located in the city center of Isparta, which is situated in the western Mediterranean region of Turkey. Isparta is bordered by Afyon to the north, Antalya to the south, Burdur, Denizli, and Uşak to the west, and Konya to the east (Figure 1).

Şekil 1. Location of study areas

The first of the study areas is the Ayazmana Promenade, established in 1996 (Serin, 2004). It is located between the Halikent and Vatan neighborhoods in the southeast part of the central district. The general area covers 18 hectares, with elevations ranging from 1030 to 1140 meters, and the dominant aspect is northward, with an average slope of 30%. A significant portion of the Promenade is covered by natural Anatolian chestnut (*Castanea sativa* Mill.) forest vegetation (Genç et al., 2001). Notably, on April 28, 2021, 17 Anatolian chestnut trees within the Ayazmana Promenade were registered as Monumental Trees (Amt Ağaç) (Anonymous 2022).

The second study area, Gökçay Promenade, is located in the southern part of the central district of Isparta, within the borders of Keçeci Neighborhood. The Promenade was established on an area of 60 hectares in 2003 (Serin, 2004).

Both Ayazmana and Gökçay Promenades, being close to the city center, are heavily used by the city's residents, especially during the spring and summer seasons and on weekends. Due to the high visitor potential, they fall under the category of Type B Promenades in the Promenade Implementation Regulation (Anonim, 2015). Both of these Promenades are owned by the Isparta Municipality.

The third study area, Milas Promenade, is located in the village of Yakaören, which is accessible from the city center of Isparta via a 10-kilometer asphalt road. It borders the Isparta Gölçük

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Nature Park and covers an area of approximately 5 hectares. In 2020, the name of the area was changed to "Milas Millet Bahçesi" (Milas People's Garden) as a result of renovation work carried out by the Isparta Governorate (Anonim, 2020). On September 30, 2009, the Antalya Cultural Heritage Preservation Board declared Milas Promenade as a 2nd-degree Natural Conservation Area (Doğal Sit) (Anonim, 2021) as part of the reevaluation of conservation statuses conducted by the Ministry of Environment, Urbanization, and Climate Change.

Milas Promenade, due to its distance from the city center, relatively small size, and proximity to the day-use area of the Isparta Gölcük Nature Park, has a moderate to low visitor potential. Therefore, it falls under the category of Type C Promenades in the Promenade Implementation Regulation (Anonymous, 2015). This area is owned by the Isparta Provincial Special Administration.

In the determination of recreational uses in the study areas, observation and recording methods were employed, and the data obtained were supported by photographs taken in the field. In this study, a SWOT analysis was conducted for the study areas to reveal their current status and provide a basis for evaluations. The analysis covered the presence of active green areas, the existing plant species used in green areas, furniture elements (seating units, lighting elements, warning and directional signs, decorative fountains, fountains, art objects, shading elements, pergolas, boundary markers, sales units, children's play and sports area elements, surface coatings, etc.), recreational uses (picnicking, sports, walking, dining, entertainment, cultural activities), and accessibility to the areas. For the identification of plant species in the study areas, Yaltrık & Efe (2000) and BITKIVT (2023) sources were utilized.

3. RESULTS and DISCUSSION

a. SWOT analysis

The SWOT analysis conducted for the Promenades is presented in Table 1. According to the analysis, the strengths of the Ayazmana, Gökçay, and Milas Promenades include their proximity to the city center, the richness of the existing flora, and the high landscape values. On the other hand, their weaknesses include inadequate cleanliness and maintenance of the areas, as well as the rugged and sloping terrain of the sites. The greatest opportunity for each area lies in their proximity to the city center and the potential for increased infrastructure development.

Table 1. SWOT analysis for three promenades in Isparta city center

Strengths	<ul style="list-style-type: none">➤ Easy accessibility from the city center.➤ Historical establishment dates of Promenades.➤ City park-like qualities of Ayazmana and Gökçay Promenades.➤ Rich existing flora.➤ Ownership by local authorities.➤ No infrastructure deficiencies.➤ Proximity of Ayazmana and Gökçay Promenades to the city center.➤ Presence of artificial and natural water sources.➤ High landscape (scenic) values of Promenades.➤ High demand from the city's population for green spaces and nature.
------------------	---

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Weaknesses	<ul style="list-style-type: none"> ➤ Promenades being dirty and poorly maintained. ➤ Incidents of vandalism in the areas. ➤ The steep and uneven terrain of Gökçay and Ayazmana Promenades. ➤ Limited accessibility to water in all areas.
Opportunities	<ul style="list-style-type: none"> ➤ The potential to serve as a green space within the city. ➤ The potential to become a significant focal point within the city. ➤ Abundance of recreational opportunities in the areas. ➤ High potential for infrastructure improvement. ➤ Increasing demand among the city's population for open green spaces and recreational activities. ➤ Proximity of Promenades to forest ecosystems.
Threats	<ul style="list-style-type: none"> ➤ Lack of regular maintenance and cleanliness of the areas, ➤ Increasing environmental, air, and noise pollution, ➤ Insufficiency of amenities (lighting, directional signs, and picnic units), ➤ Vulnerability to earthquakes.

b. Furniture analysis in the studied promenades

Urban furniture elements are crucial components that define the areas they are located in and facilitate both individual and societal life within a city. They contribute significantly to the formation of a city's identity by providing functional and aesthetic features to the area (Kuter & Kaya, 2019). It is well-known that these elements should be in harmony with open green spaces, ensuring the necessary safety and ergonomic conditions, and featuring designs that enhance the quality of life for users (Akten & Yücedağ, 2022).

i. Ayazmana promenade

Ayazmana promenade a total of 16 furniture elements, which include lighting fixtures, seating groups, parking lots, trash cans, warning and directional signs, bicycle parking, sales units, a restaurant, a cafeteria, decorative fountains, sculptures, a theater area, toilets, fountains, children's playgrounds, and sports facilities. Among these, 8 are well-maintained, and 6 are considered sufficient (Table 2; Figure 2).

Table 2. Furniture analysis for Ayazmana promenade

	Existence	Maintenance	Adequacy

Figure 4. Lighting units, amphitheater, trash bins, and sale units in Ayazmana promenade

In the case of the lack of recreational use in the Ayazmana promenade, the most fundamental issues are pollution and inadequate facilities. Similarly, Gülez (1990) stated that recreational facilities enhance the potential of the area. There are no pathways for disabled citizens in the

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Ayazmana Picnic Area. The amphitheater, trees or shrubs, children's play areas, and many seating groups in the area are at serious risk of vandalism. In a similar study conducted by Candan et al. (2019) in the same area, it was noted that writing and drawing on tree trunks were the most common examples of vandalism.

ii. Furniture analysis in Gökçay promenade

The amenities in the Gökçay promenade include a parking lot, a children's play area, a walking path, lighting fixtures, seating groups, pavilions, warning and directional signs, restrooms, and a fountain, among others. There is a total of 18 types of amenities in the area, with 12 of them being well-maintained and 10 of them being sufficient (Table 3; Figure 5).

Table 3. Furniture analysis in Gökçay promenade

	Existence	Maintenance	Adequacy
Playground	Yes	Well-kept	Adequate
Sales unit, buffet	Yes	Well-kept	Adequate
Cafe, restaurant	Yes	Well-kept	Adequate
Walking trial	Yes	Neglected	Inadequate

Warning and orientation signs	Yes	Neglected	Inadequate
Toilet	Yes	Well-kept	Adequate

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 5. Playgrounds, parking lots, and sale units in Gökçay promenade

The inadequacy and lack of maintenance of facilities such as children's play areas, sports facilities, seating groups, and parking lots, which people prefer to use for recreational activities, can affect the potential for the area to be preferred by the urban population. Therefore, the facilities to be located should be in harmony with the natural balance of the area and its beauty without disturbing it. In a similar study, Yücedağ & Yelsiz (2022) found that the reasons for people visiting a Promenade include the area providing a calm and peaceful environment, picnicking, nature walks, connecting with nature, and its proximity to the city center.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 6. Lighting units in Gökçay promenade

The lighting elements in the Gökçay Promenade, including different designs of adjacent lighting elements with approximately 3-meter spacing in some places and the use of different lighting elements throughout the area, create an aesthetically unfavorable appearance for the area (Figure 6). In open green areas and Promenades, inadequate and improper lighting by lighting elements can lead to security issues in these areas (Candan et al., 2019). There is a decorative pool in the center of the area, and there are irregularities on the walking paths within the area, as well as trees and barbecue grills on the sidewalks (Figure 7).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Figure 7. Ornamental pool, walking trails and parking lot in Gökçay promenade

The Gökçay Promenade features numerous seating groups, picnic units, gazebos, fountains, toilets, and various architectural structures. There is also an amphitheater, a restaurant, and an entertainment center (such as a wedding hall, etc.) where many activities take place in the area (Figure 8).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Seating groups are important elements that serve significant functions and are frequently used. These elements should be appropriately located and provided in sufficient numbers within the area. In the Gökçay Promenade, it was found that the seating elements were suitable in terms of quality and features but had deteriorated due to heavy use and were no longer usable. Since people visiting the area engage in activities such as nature walks, sports, picnics, and being in close contact with nature, it is essential to have a sufficient number of well-maintained seating elements. Similarly, Yücedağ & Kaya (2017) found that the Gökçay Promenade is visited by people for purposes such as walking, picnicking, and spending time in nature.

Accessibility to a Promenade is proportionally important to its recreational potential. Akten (2003) stated that the more people benefit from an area, and if they do not encounter transportation problems, the recreational potential of that place increases significantly. Due to its proximity to the city center, the Gökçay Promenade is heavily used by the local population. The primary issue is the irregular and insufficient parking areas due to the intense use of the area by people. In a similar study conducted in the Gökçay Promenade (Yücedağ & Kaya, 2017), the inadequacy of the parking lots and the need for appropriately sized parking areas were highlighted.

iii. Furniture analysis in Milas promenade

The furniture elements found in the Milas Promenade, which is the subject of the study, include children's playground, sales units, cafeteria, lighting fixtures, seating groups, parking lot, fountain, toilet, garbage bins, sports facility, directional signs, and picnic tables, among others, totaling 15 types of furniture. Of these existing furniture types, 6 are well-maintained, while 5 are considered sufficient (Table 4; Figure 9-10).

Table 4. Furniture analysis in Milas promenade

	Existence	Maintenance	Adequacy
Playground	Yes	Neglected	Inadequate
Sales unit, buffet	Yes	Well-kept	Adequate
Cafe, restaurant	Yes	Well-kept	Adequate

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 10. Walking trail, toilet, masjid, ornamental pool, poulties, orientation signs and trash can in Milas promenade

Milas Promenade, due to its proximity to the city center and easy accessibility, is heavily used by the public, especially on weekends. It serves as a recreational space for children to play, families to have picnics, and for various recreational activities. The area features seating groups,

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

picnic units, walking paths, fountains, toilets, a small mosque, and other amenities. Despite the high usage of the area, facilities like children's playgrounds, seating groups, and lighting fixtures are insufficient and poorly maintained in comparison to the size of the area. The absence of suitable walking paths for disabled citizens is also a concern.

c. Comparison of the furniture in promenades

As a result of the comparison of the Promenades in terms of their amenities, it has been determined that Gökçay Promenade has more amenities, better-maintained facilities, and sufficient infrastructure compared to the other Promenades. On the other hand, Milas Promenade, despite its heavy use by the public, has fewer amenities, poorly maintained facilities, and lacks the necessary adequacy in terms of infrastructure (Figure 11).

Figure 11. Comparison of promenades in terms of furniture (Total furniture=18)

d. Main plant species in promenades

Plants are one of the most important elements of open-green spaces (Kuter & Erdoğan, 2010). Plant species can transform the areas where they are used into more livable and recreationally potential spaces (Karaşah & Var, 2012), and the selection and appropriate use of plant species in these areas are of great importance (Toprak & Yücedağ, 2022). It has been determined that the main plant species in Ayazmana, Gökçay, and Milas Promenades are either naturally occurring or artificially planted. These species are generally found to mitigate noise pollution, provide shade, and create a pleasant climate in the areas. In Ayazmana Promenade, 9 broad-leaved and 2 needle-leaved (a total of 11) plant species were identified. In Gökçay Promenade, 12 broad-leaved and 3 needle-leaved (a total of 15) plant species were identified, while in Milas Promenade, 6 broad-leaved and 6 needle-leaved (a total of 12) plant species were identified (Table 5).

4. CONCLUSION and SUGGESTIONS

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

In this study, it has been revealed that Gökçay Promenade has more facilities, better maintenance, and is more sufficient compared to other Promenades. Gökçay Promenade, being one of the most popular Promenades for the residents of Isparta due to its proximity to the city center, should consider removing the trees along the walking paths, especially if they hinder visitors' use of these paths. Additionally, measures should be taken due to the proximity of decorative fountains to the children's playground. One of the main shortcomings of the area is the insufficiency of picnic units and seating groups, which are essential for the basic purpose of picnicking for visitors. The different types of lighting elements used in the area were not found aesthetically suitable. Maintenance efforts in the area should be increased.

For Ayazmana Promenade, it was found that there is a lack of lighting elements and seating groups, and the road-side parking system is irregular and insufficient. Recommendations for improvement include installing lighting elements in a homogeneous distribution within the area, maintaining and repairing existing seating groups, increasing their numbers, and developing a specific design for the parking area, separating it from the roadside and expanding it. The area where historical (monument) Anatolian chestnut trees are located should be designated as a special zone, walking routes should be prepared, picnic units should be removed from that area, and information and warning signs for visitors should be placed. Additionally, scenic viewpoints should be identified.

Milas Promenade, which is intensively used by the public for activities such as nature walks, picnics, relaxation, and various recreational activities within the forest ecosystem, has fundamental deficiencies in terms of lighting elements, trash cans, and seating groups. Regular cleaning and maintenance procedures are necessary to address issues related to cleanliness. In forest ecosystems, the use of recreational resources is primarily due to their natural and aesthetic values. Therefore, in such areas, both infrastructure and superstructure arrangements should be made in a way that recreational activities do not disrupt the natural structure of the environment. Sustainable use of natural resources requires the improvement of infrastructure and superstructure in the studied Promenades, diversification, and an increase in recreational activities. This can increase the recreational potential of these areas.

It was found that the furniture elements in the studied areas are damaged by the public during their use. To prevent such damages, the public should be informed and warned through various communication channels. Measures should be taken to prevent vandalism damages to the furniture elements in the areas. In landscape design and implementation projects, elements that hinder human use should not be included in sidewalks and walking paths. In future botanical design projects for the studied areas, the use of plant species with high aesthetic value and plant diversity will increase the recreational value of the areas.

In conclusion, it is crucial for the future planning and management of the natural resources in the three Promenades, which are of great importance to the city of Isparta, to carry out periodic arrangements, maintenance, control, and protection work in the areas. Functional and managerial new approaches should be established and implemented as soon as possible.

ABSTRACT

The history of humanity has a rich and diverse history with numerous civilizations and cultures. Cultural heritage sites preserve this heritage as an urban memory that can be passed on to future generations. However, rapidly increasing urban development, unpredictable natural disasters and complex socio-political dynamics are serious risks that threaten the sustainability of these heritage assets. Hasankeyf, with its thousands of years of history and hundreds of archaeological sites, has been one of the cultural treasures under risk. The major change in the city due to the Ilisu Dam project has aroused widespread repercussions at the international level and it has reminded that the preservation of cultural assets should include not only tangible assets, but also historical memory and knowledge. Therefore, documenting and archiving historical and cultural assets in detail is crucial before their permanent transformations. In this study, photogrammetric models of Hasankeyf were created with Metashape software using old drone images. Then, a photogrammetric model of the area was created using the latest drone images in order to make a process evaluation. Then, the transformation of Hasankeyf was examined through the models obtained and the transformation was visualized. The interaction between cultural heritage and technology has gained great importance in preservation studies in the digital age of rapidly developing technology. This study highlights the possibilities that digital technologies can present in the preservation of cultural heritage and demonstrates the increasing necessity of documenting historical values. It also provides a framework for documentation of similar historical heritages.

Keywords: Cultural Heritage, Digital Tools, Photogrammetry, Hasankeyf, Türkiye.

1. INTRODUCTION

Cultural heritage is the totality of tangible and intangible elements that reflect the identity, history and cultural values of a community, people or nation. Tangible and intangible cultural heritage includes aesthetic-artistic, historical-documentary, symbolic, socio-economic, religious and spiritual, and even political values. In addition, cultural heritage is the manifestation and proof of the existence, characteristics and cultural continuity of human beings, societies and cultural groups that make up society (Halaç & Öğülmüş, 2021). The conservation of cultural heritage is critical for passing on the history, identity and cultural values of societies to future generations. However, numerous factors such as globalization,

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

rapid urbanization, environmental degradation and economic pressures make cultural heritage conservation challenging and complex. In these challenging circumstances, digitalization is often proposed as a solution. With the rise of digital technologies, there is a growing interest in the idea that cultural artifacts and structures can be preserved digitally, creating a wider accessibility and even a more active role for society in this process. In addition, digital data play an important role in the preservation and sustainability of cultural heritage, as they serve as documents. The opportunities offered by digitalization are not only in document creation. Digitalization also includes features such as documentation and research, digital archiving and cataloging, global outreach and education, virtual tourism and observation, digital restoration and simulation, community engagement and crowdsourcing, benchmarking and tracking, digital exhibitions and museums, and many other interactive experiences that help carry cultural heritage to future generations.

Developments in the technologies used in the documentation and representation of cultural heritage have forced experts working in this field to think about the effects of technology, its benefits and the resulting possibilities. The digital documentation obtained with this technology allows the production of a simplified model of the object that allows the transfer of the necessary information and contains sufficient information, instead of the model produced by traditional methods, which consists of drawings that define the geometry of the object and pass through reference sections that divide the space horizontally and vertically. Such representation methods not only allow the direct extraction of metric information, but also facilitate our understanding of the object while forcing us to select the most important parts to simplify the object (Korumaz et al., 2011). In this context, two-dimensional and three-dimensional digitization of heritage data in today's studies is becoming a common practice in cultural heritage areas. This process, which can be explained by the term "digital heritage", is used intensively by international institutions such as UNESCO, which have studies in the field of cultural heritage, and it is intended to reveal the cultural values of societies together with the principle of digitization and to be presented to us as digital information (Töre, 2018).

Documentation in cultural heritage should be based on the current state and historical past of the building, its structural layout and deterioration rates, as well as material analysis, and should also include the features that determine the morphology of the building and its current state and the interventions it has undergone over time (Tucci, 2009). In recent years, developing documentation techniques offer fast, reliable and cost-effective solutions in many different fields. When the studies in the literature are examined, it is seen that photogrammetry, which is one of the most important methods of digital documentation techniques and used in this study, can be used for determining coastal areas (Gonçalves & Henriques, 2015), monitoring land use change, determining urban areas, monitoring forest destruction, green area detection, flood analysis, volume calculations (Ulvi, 2018; Kaya, et al, 2019; Minařík & Langhammer, 2016), modeling of historical monuments (Şasi & Yakar, 2018; Galantucci & Fatiguso, 2019; Yılmaz, et al., 2008), cultural heritage sites (Yastıklı, 2007; Hassani, 2015; Dostal & Yamafune, 2018), structural analysis of historical buildings (Kutlu, et al., 2023; Barille et al., 2016).

With its history, Hasankeyf has the characteristics of a museum city with its immovable cultural heritage, multi-layered historical structure, topographical features and the current conditions it has reached today. In this study, it is aimed to reveal the possibilities provided by digital tools in protecting cultural heritage and documenting and analyzing the change of cultural heritage on an urban scale through Hasankeyf.

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

In this context, photogrammetric models of Hasankeyf were created with Metashape software using old drone images. Subsequently, a photogrammetric model of the flooded old settlement area was created using the most recent drone images in order to make a process evaluation. Hasankeyf's transformation was analyzed through the models obtained. The fact that the models provide an opportunity to address the city in a holistic manner has allowed to clearly see the transformation of the historical area of Hasankeyf and the transformation of the city in the process has been revealed on an urban scale.

2. MATERIALS and METHODS

2.1. General information about Hasankeyf

Hasankeyf, formerly known as Hisn-ı Keyfa, is located in the province of Batman in the Southeastern Anatolia Region of Turkey. "Hisn-ı" The Arabic "Keyfa" is Syriac and both mean "rock". Hisn-ı Keyfa also means "Yalçın Rock Peak" (Umar, 1993). The history of the district dates back to approximately 12,000 years ago. Hasankeyf, which has been home to many civilizations in history, contains rich cultural heritage structures. According to records dated 1530, Hasankeyf, which was under Ottoman rule, had 4 mosques, 11 zawiya, 30 masjids, 2 caravansary and 4 baths (Baluken, 2016: 310-335). Hasankeyf was declared a natural protected area by the Ministry of Culture and Tourism in 1981 (Çoban, et al. 2017; Yeşil and İnal, 2019; Öncül and Alpaslan, 2014; Öztürk, et al., 2021). The city is accessible to Batman and Mardin from the west and Midyat and Gercüş from the south (Figure 1). Hasankeyf, which is an important tourism center with its historical and natural beauties, is visited by many local and foreign tourists.

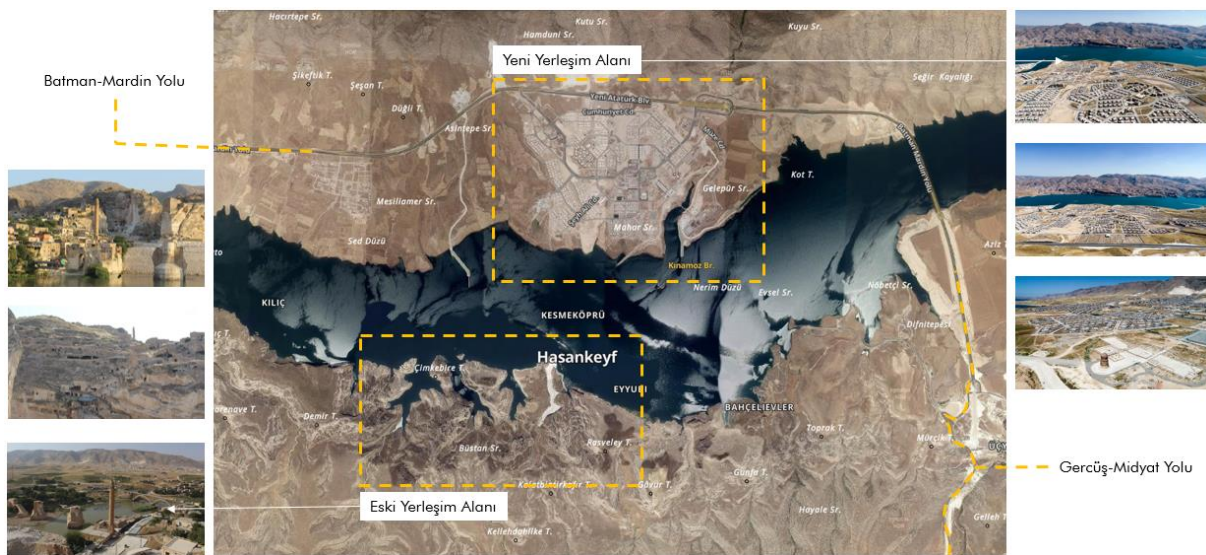

Figure 1. Hasankeyf city boundaries and views (Edited from General Directorate of Mapping)

The geological structure of Hasankeyf consists of cave dwellings created by natural and man-made processes due to its limestone structure that can be easily carved. The appearance of its rocky terrain with valleys and hills formed by natural factors over thousands of years is one of its most important features (Arik, 2003: 13). While excavations were continuing in Hasankeyf, located on the banks of the Tigris River, the construction of the Ilisu Dam Project began. In May 2020, as a result of the dam built on the Tigris River, the historical settlement of Hasankeyf

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

was flooded. For this reason, rescue excavations and works for the transportation of historical artifacts were carried out in Hasankeyf before it was submerged under the waters of the Ilisu Dam. Protection and transportation works were carried out in cooperation with the General Directorate of State Hydraulic Works and the General Directorate of Cultural Heritage and Museums (Sevgi & Yılmaz, 2020). The historical buildings moved to the archaeopark area organized in the new Hasankeyf settlement area were prevented from being flooded.

2.2. Data Collection

Data collection method is the research technique used to obtain data that will bring the research subject to the conclusion. Depending on the research topic, data collection can be done in various ways such as document analysis, questionnaire, interview, observation, experiment (Symon & Cassell, 1998; Yıldırım, 1999).

Due to the relocation of historical buildings to the new settlement area in Hasankeyf district, data collection studies on the old city views were carried out first. Extensive online publications and research on image acquisition were conducted. Following the acquisition of data on the old city, data research on the new city views was carried out. Especially the existing images obtained from unmanned aerial vehicles (drones) provide important data for the city as a whole. The data obtained was used as a base in the study in order to reveal the old and new urban texture of the region.

2.3. Digital approach to documenting cultural heritage

Two stages are very important in the cultural heritage process. The first one is data collection and the other is the decision-making process. The data collection phase is a process that also affects the decision-making process and should be followed carefully. According to Boehler and Heinz (1999), the decision-making process in the study of cultural heritage involves first deciding what to document and then selecting the appropriate methodology in consultation with experts from other disciplines.

With the developing technology, the methods used in documenting historical values are also changing and developing. The use of modern techniques in historical buildings and cultural heritage studies has provided great convenience over time compared to traditional methods (Balçı, 2022). Although these methods have diversified over time, the margins of error have gradually decreased, time savings have increased, manpower burden has decreased, and it has progressed digitally to 3D documentation (Masciotta et al., 2021; Reunanen et al., 2015; Korumaz et al., 2011). It is easier, faster and more precise to take detailed measurements, make drawings, take photos and videos, and obtain 3D data from drawings. In addition to all these, modern techniques provide the opportunity to store the obtained precise and visually rich data in a digital environment for a long time.

In this study, photogrammetry, one of the 3D modeling techniques enabled by today's technology, was used. Photogrammetry means measuring with the use of photos and enables the creation of a 3D model from photographs (Gienko & Terry, 2014; Yılmaz, et al., 2007; Şenol, et al., 2021). In general, photogrammetry is a science in which reliable information about objects and the environment is obtained as a result of the recording, measurement and interpretation of photographic images shaped by the rays emitted from the objects and the environment they form, and the electromagnetic energy they emit (Figure 2). There are different photogrammetric classifications such as terrestrial photogrammetry and aerial photogrammetry

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

according to the technique of obtaining images. In this study, aerial photogrammetric technique was used. Aerial photogrammetry is a technique used to create maps, models, and measurements from aerial photographs. It involves capturing overlapping aerial images and using them to extract 3D information about the terrain or objects of interest.

Figure 2. Process flow chart of 3D photogrammetric model production with aerial images used in the study

3. FINDINGS

In this study, Hasankeyf data were analyzed in two different periods, before and after 2019, with reference to the water filling of the Ilisu Dam and the hydroelectric power plant in August 2019. Photogrammetric models were created for both periods in order to ensure an effective and holistic analysis of the periods. The cultural heritage data were analyzed through the digital three-dimensional models created in the study. These models were created with real measurements using the program's depth detection algorithm.

In order to present the change of the region with digital tools, the change of the old and new settlement areas of Hasankeyf over time was mapped on 2D Google Maps. Prior to 2019, a 3D photogrammetric model of the area was created in addition to the 2D map. The model indicates the locations of the cultural heritage structures in the area at that time. In the period after 2019, an updated photogrammetric model was created to show the condition of the flooded old settlement area. In the study, a model was also created for the new settlement area in the city, where a process of cultural heritage relocation was managed, and the new locations of the relocated cultural heritage were also indicated.

3.1. Hasankeyf – Before 2019

In the study, existing drone images were used to create a model of the Old Hasankeyf settlement area. The photogrammetric software program Metashape (developed by Agisoft) was used to obtain the images. The program has algorithmic features that can detect depth from the acquired

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

images. In order to create a photogrammetric model of the Old City of Hasankeyf, 174 photographs were added to the program.

In order to perceive depth from photographs, they must be overlapped and taken from different angles. Otherwise, the program cannot identify and align the images. The program aligned 138 out of 174 images obtained for Old Hasankeyf. After the alignment process, a model is formed from the point cloud. Upon completion of the alignment process, build dense cloud is created. The build dense cloud allows to create a denser point cloud than the base points that can be aligned from the photographs. With the creation of the dense point cloud, the "built mesh" process of converting the points into meshes was realized. The textures of the defined photographs were transferred to the model consisting of networks by "build texture" and "build tiled model" operations. Thus, the Old Hasankeyf model creation process was completed (Figure 3).

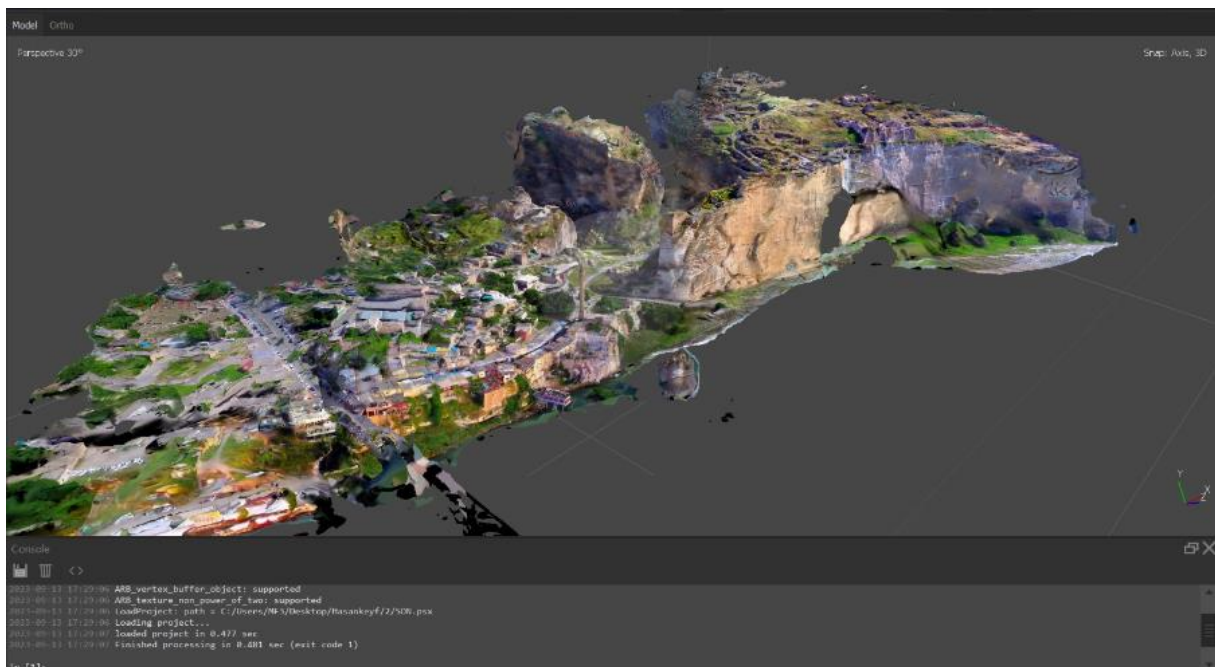

Figure 3. Photogrammetric model produced within the scope of the study for Hasankeyf old settlement area

At the beginning of the 21st century, the Ilisu Dam Project created the need for a new settlement area for Hasankeyf. This area was evaluated as the foothills of the mountain in the northern direction of the old settlement area and across the river. The new settlement area, which has a flatter terrain compared to the old settlement area, started to be built quickly after the decision was made (Figure 4).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

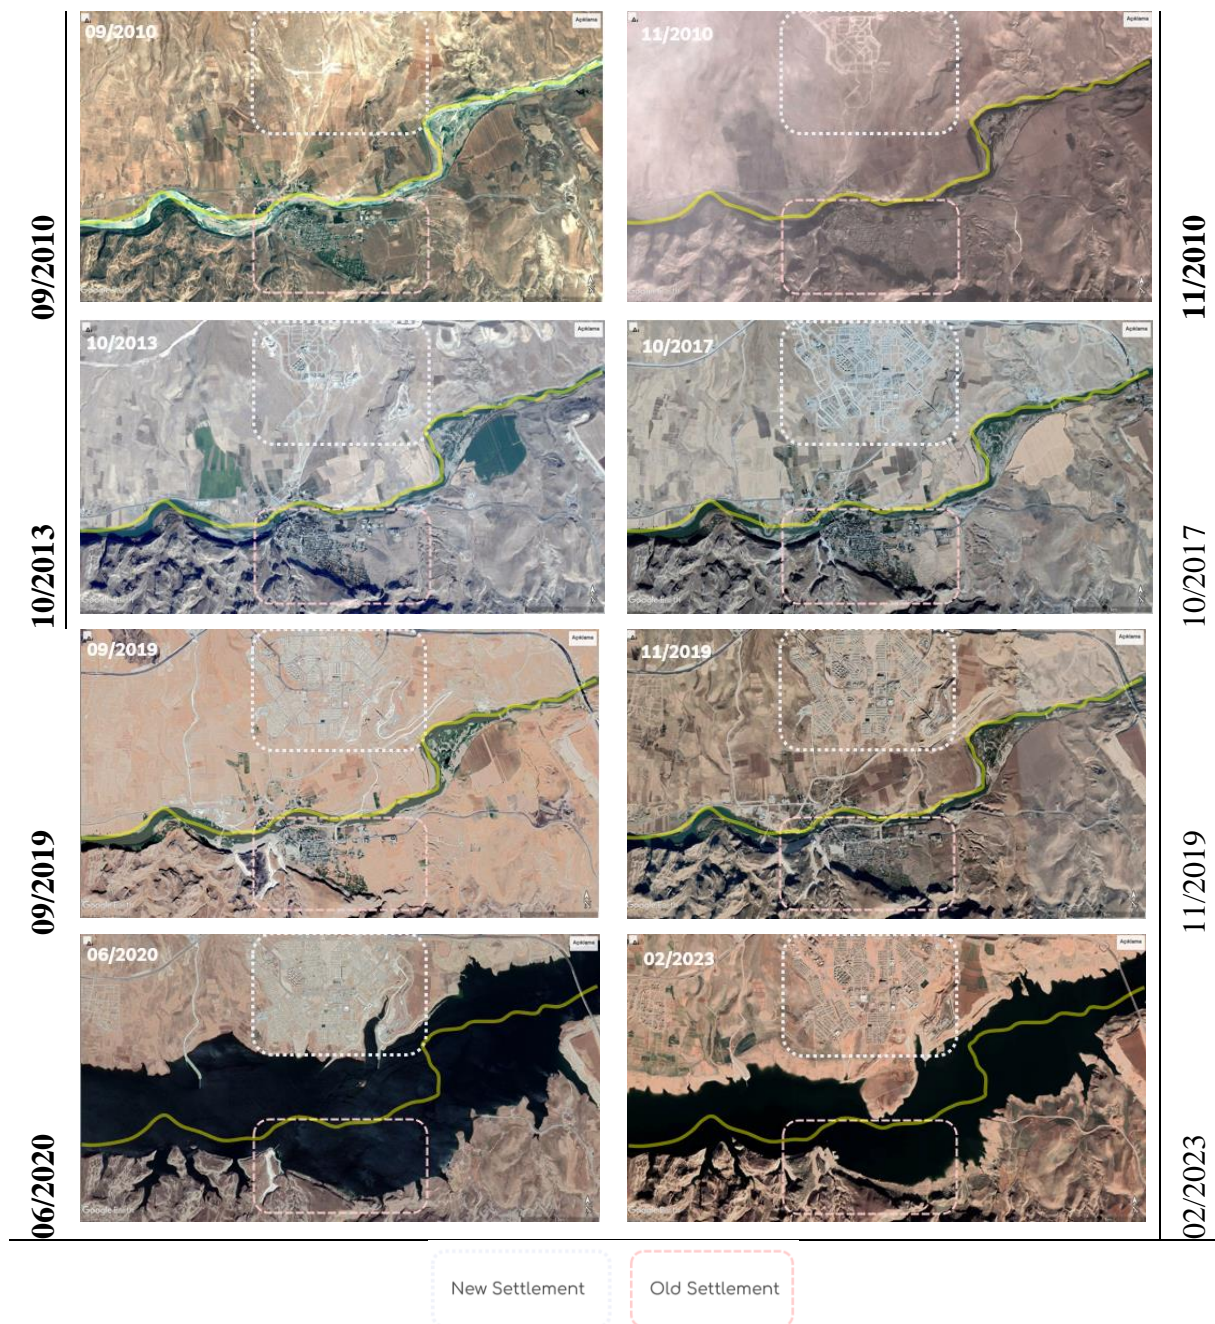

Figure 4. Historical development of Hasankeyf settlement area

3.2. Hasankeyf – After 2019

In order to make a comprehensive assessment of the old and new settlement areas, models were created for both the current situation of the old settlement area and the new settlement area of Hasankeyf after 2019.

The flooded model of the old settlement area was created with data from 2021. 133 photographs of the settlement area were added to the program and the program recognized and aligned all

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

these photographs. After the alignment process, the dense point cloud generation was performed and the process was completed by generating a model consisting of meshes (Figure 5).

Figure 5. Hasankeyf eski yerleşim alanının su altında kalan durumunu gösteren fotogrametrik model

With the flooding of the Hasankeyf settlement area, the issue of relocation of both civilian life and cultural heritage has arisen. Immovable cultural heritage sites known as Zeynel Bey Tomb, Artuklu Bath, Imam Abdullah Zawayah, Kızlar Mosque, Middle Gate, Süleyman Han Mosque and Er Rızk Mosque were moved to the Archaeopark Cultural Area due to the risk of being submerged under the Ilisu Dam and Hydroelectric Project (HES). This new settlement area is located approximately 2 km north of the old settlement area from a bird's eye view. As part of the study, a photogrammetric model of the area was created in order to see the legibility of this area and the new locations of the historical buildings on an urban scale. To create the model, 283 photographs were used and the program created a photogrammetric model of the area by identifying 271 of these photographs (Figure 6).

4. Evaluations and Discussion

The tools used in the conservation and documentation of cultural heritage are changing and evolving with the development of technology. The method of photogrammetry used in this study has spread rapidly with the development of photographic techniques and computer software in the mid-20th century. Considering the identification process of the photographs used in photogrammetric model making, the process may not be a single step, and the program may not be able to align all the photographs taken. Therefore, it may be necessary to take new photos in the field. Photographs that cannot be identified by the program are detected by the program interface. New images should be taken from the same or similar angle using the "overlap" technique, paying attention to the previously identified image.

The new images can be aligned with the previously taken images by adding them back into the program. The problem with unidentified photos is usually that the images are not of similar daylight, size, and resolution quality. The visibility of the surfaces in the camera angle is one of the most important factors of the model quality. It is recommended that images be taken before hours of intense shade or intense sunlight. The 3D model obtained by photogrammetry is dimensional. However, it is recommended to check the dimensions of the models against an object whose real dimensions are known and to rescale them if necessary. One of the most important advantages of a scaled model is that important data measurements for surveys required for conservation and documentation studies can be obtained from 3D models.

When Hasankeyf is considered through the models created within the scope of the study, the transformation of Hasankeyf can be clearly seen. When this transformation process is evaluated within the scope of the models created;

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

- Examining Figure 7, it can be seen that old Hasankeyf, where the historical urban fabric is integrated with socio-cultural life, is completely submerged, while a part of Hasankeyf Castle is still above the water, can still be visited, and contains important cultural structures.
- Examining Figure 8, it can be seen that the original stairs that provided access to the castle and the area where the caves were located, which were among the first settlement areas, were covered with fill material in order to control the water from the dam.

Figure 7. Historical Hasankeyf settlement and flooded areas

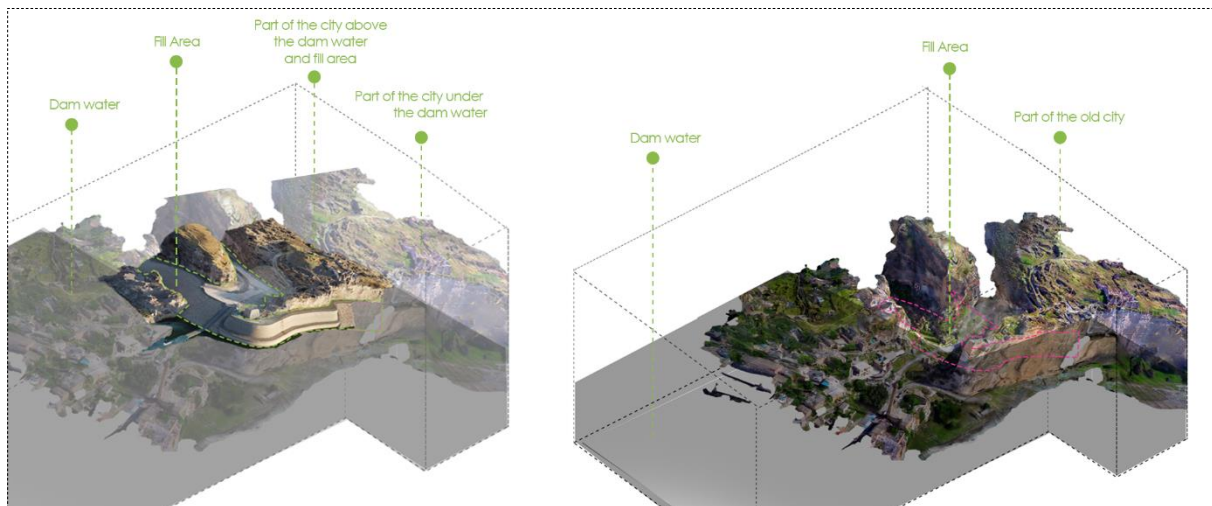

Figure 8. Regional locations of the embankment operations for the dam

- Examining Figure 9, the Archaeopark Cultural Area can be seen where the historical buildings that will be flooded by the Ilisu Dam have been relocated. The urban life and cultural heritage areas, which form an integrity with the civilian life of Hasankeyf, are located together in the new settlement area. The Archaeopark area has become an area that ensures the protection of individual structures.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

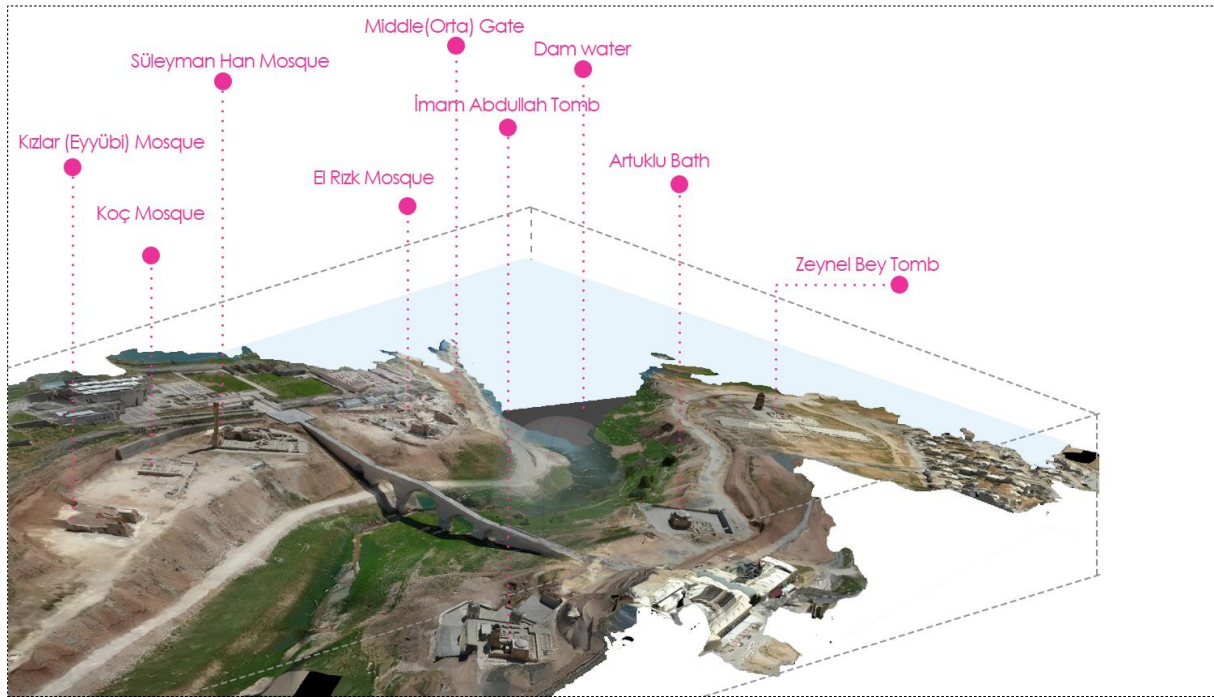

Figure 9. Photogrammetric model showing Hasankeyf new settlement area and Archaeopark Cultural area

Hasankeyf is a settlement with a rich historical and cultural background. It has historical buildings, caves and ancient ruins. For this reason, submerging under water also means losing the eye-catching effect of the cultural heritage. Although the tangible cultural heritage has been transferred to the new settlement area, the intangible cultural values have not been transferred. It can be said that in a region where abstract cultural values and feelings of belonging cannot be transferred, the original values of the region are also lost, and it will take many centuries to recreate these values in a new settlement area.

Although large-scale infrastructure projects such as the Ilisu Dam create a cycle in terms of resource production and consumption, their environmental impact is quite high. Such large-scale infrastructure projects can often cause conflicting emotions and different opinions. In this context, it is necessary to ensure the sustainability of all the physical, social and cultural values in the area without ignoring them when dealing with large-scale infrastructure projects, which are also a current topic of debate.

5. CONCLUSION

One of the primary rationales for integrating the concept of digitization with cultural heritage is the belief that sustainable documentation can be achieved by transferring heritage data requiring preservation to a digital medium. Consequently, this study has shed light on the significant role that digital methodologies can play in documenting the complex cultural heritage dynamics of Hasankeyf, a site of historical importance yet faced with various contemporary challenges.

Researchers are able to create a comprehensive digital archive that captures not only the physical elements of the heritage site but also its socio-cultural and historical dimensions through a multi-faceted approach incorporating digital mapping, 3D modeling, and interactive

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

databases. Digital tools discussed, ranging from GIS to drone-based photogrammetry, offer scalability in modeling and analysis, thus presenting a significant opportunity for the preservation or reconstruction efforts of Hasankeyf. These technologies also democratize the documentation process, allowing the community to actively participate in and contribute to the discourse surrounding their own cultural heritage.

While the digital approach offers numerous advantages, its limitations should not be overlooked. Technical constraints, resource limitations, and issues of digital preservation must be addressed to ensure that the generated data remain accessible and interpretable for future generations. Ethical concerns related to data ownership, representation, and inclusivity also necessitate further research. As we advance in the age of digital innovation, the need to leverage these technologies not merely as repositories of information but also as dynamic platforms for storytelling, dialogue, and mutual understanding becomes increasingly important. This study takes a significant step in preserving its rich history for future generations by documenting Hasankeyf's cultural heritage through a digital approach. At the same time, it lays the groundwork for data sets intended for future initiatives in heritage conservation, urban transformation and redevelopment.

ABSTRACT

"Sustainability" is a concept that emerged with the aim of meeting the needs of future generations without compromising the needs of present generations and has become a global implementation plan through international agreements towards the end of the 20th century. Economic growth, social development, and effective environmental conservation are three essential elements that cannot be ignored for sustainable development. While environmental and economic sustainability entered the literature during the same period, the definition of social sustainability followed a variable process. It evolved from a definition that focused on meeting basic human needs such as food, shelter, education, and health to a more differentiated and complex dimension in terms of indicators. This evolution is essential for sustainable development, which aims to ensure the transmission of a sustainable future to the next generations. The concept of social sustainability has its roots in the social sciences and has reached an ever-expanding research area with undefined boundaries. Finding a common definition and comprehensive framework for social sustainability in the literature has become challenging due to the diverse approaches taken by various disciplines since the 19th century. In this context, the purpose of this article is to present the definitions of "social sustainability" attempted by various disciplines and provide a descriptive framework. The study compiles and presents different definitions of social sustainability that have been proposed since the 19th century, aiming to offer a comprehensive perspective on the concept. The study employed a literature review method to gather data.

Keywords: Social Sustainability, Social Sustainability Definitions, Architectural Social Sustainability.

1. INTRODUCTION

With the increasing population in the 19th century, the utilization of natural energy resources increased. In the 20th century, advancing technology rapidly depleted the earth's natural resources, leading to a significant increase in environmental issues. In this context, intensive efforts have been initiated to find solutions that consume resources minimally, protect the environment, and ensure sustainability (Mengi and Algan, 2003). The concept of "sustainability," which is included in the "World Conservation Strategy" document adopted by I.U.C.N in 1982, entered the architectural literature with the publication of the book "Ecological Construction (Ökologisches Bauen)" in 1982 by the directives of the German Ministry of Environment (Özbayraktar, 2017). In this book, information about natural and artificial

environments, the functioning of active and passive systems, and the main approaches of ecological design were presented through illustrations and graphics. This book has been referred to as the "Neufert" of ecological architecture (Tönük, 2008). Up until 1987, the prevalent development approach worldwide, which disregarded the environment and focused on society and economy, was replaced by the concept of "sustainable development," as first defined in 1987 through the report "Our Common Future," also known as the Brundtland Report, prepared by the World Commission on Environment and Development. This report shapes the environmental issue within the framework of the interconnected relationships among poverty, inequality, population growth, and environmental degradation. It proposes a new development model that is environmentally compatible for all countries and introduces the concept of "sustainable development" (World Commission on Environment and Development, 1987). Sustainable development, which was introduced in 1987 and rapidly entered the architectural literature, is defined as sustainable architecture in the architectural context and is achieved through three fundamental principles:

- Conservation of resources; reduction, reuse, and recycling,
- Life cycle,
- Human-centered design (Kim and Rigdon, 1998).

In 1999, the International Council for Research and Innovation in Building and Construction (C.I.B.) provided a detailed explanation of the fundamental principles of sustainable architectural design, encompassing three main dimensions: economic, environmental, and social aspects (C.I.B., 1999). Despite efforts to create a shared understanding of the three main components defined for sustainable architecture in the literature (Sachs, 1999; Williamson, 2007; Pressoir, 2008; Çahantimur, 2007; Becker, 1999; Sakınç, 2010; Kohler, 1999), it is observed that there is no common definition of social sustainability in the literature, and it has evolved over time with different scopes and perspectives.

2. SOCIAL SUSTAINABILITY

Social sustainability, broadly defined, encompasses the conservation and augmentation of societal circumstances conducive to fulfilling human requirements and upholding environmental viability. Its core purpose lies in the judicious utilization of natural assets by both current and forthcoming generations (Çahantimur, 2007). A multitude of contrasting interpretations pertaining to social sustainability abound. These elucidations typically center on well-defined objectives like impartial access to opportunities and resources, alongside an equitable apportionment of advantageous and detrimental consequences (McKenzie, 2004). They underscore the significance of democratic frameworks that guarantee entry to decision-making mechanisms, coupled with communal interactions that foster the accumulation of social resources on localized and broader planes (Bramley and Power, 2009). Moreover, the interpretations presented underscore the significance of inclusion, tolerance, and the underlying societal framework that bolsters unity within thriving societies, with the aspiration that these societies attain elevated levels of communal welfare (Anand and Sen, 1994; Sen, 2013; Opp, 2016; Shirazi and Keivani, 2017). From this vantage point, 'community' is delineated as clusters or networks interlinked by relatively enduring social bonds formed around shared affiliations or interests (Marshall, 1998). Within local communities, in-person interactions emerge as the elemental components fostering interconnection and unity (Goffman, 1972). When scrutinized

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

through the lens of social sustainability literature, it becomes evident that the criteria and delineations in this domain remain incomplete within both architectural practice and literature (cf. Woodcraft et al., 2012; Opp, 2016). To be sure, the spatial dimensions entwined with social sustainability have been explored within the realm of architecture. To illustrate, Mumford's 1953 discourse on "urbanity" encapsulated the praiseworthy facets of urban existence, encompassing a sophisticated collective urban life and individual gratification. Antecedent viewpoints on "urban life," such as Park's (1915) treatise on "Human behavior in the urban environment" and Wirth's (1938) exploration of "Urbanism as a way of life," are notable. Subsequently, in the 1960s, Jane Jacobs made seminal contributions concerning "vitality" and "successful neighborhoods," particularly in the context of architecture. These ideas have more recently manifested as the concept of "livability" (James, 2015). The fundamental objective of social sustainability resides in probing the dynamics between communities and their proximate surroundings. In essence, social sustainability seeks to comprehend the interplays, correlations, and repercussions between individuals and the spaces they inhabit, striving to harmonize and enhance these connections in a sustainable manner. It accentuates a heightened grasp of and adeptness in navigating the interplay of social and spatial circumstances, all while considering the well-being of communities, equity, and safeguarding the environment (Bilge, 2007).

Table 1. Social Sustainability Definitions From Literature (Source: Authors)

AUTHOR	SOCIAL SUSTAINABILITY DEFINITIONS IN LITERATURE
MCKENZI	A life enhancing standards in society, and an affair within communities which can attain the condition.
MEHAN&SOFLAEI	The pride of simple human needs and succeeding maintenance for future generations.
LITTING&GRIESSLER	A systematic concept, but its aspects are separated, leading to confusion in the sequence process.
AJMAL, KHAN, HUSSEIN & HELO	A quality of society especially for susceptible humans or groups.
BARRON&GAUNTLETT	In formal and informal ways, administrations, structures and connections busily support the magnitude of new generations to build healthy and quality living standards for the community.
PALICH&EDMONDS	A process aimed at designing sustainable and successful spaces to increase people's well-being by understanding what they need where they live.
ISO 21929-1:2011	The right of all mankind to benefit equally within the scope of health.
BERARDI	The keywords of social sustainability such as flexibility and adaptability.

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

ANDERS	Human-centred quality of life, "human well-being", nature-centered "environmental well-being" and it refers to the situation of "having a good place" based on space.
BRAMLEY&POWER	It is associated with the provision of social equity (social equity), social inclusion (social inclusion) and social benefits (social capital).
DEMPSEY	It is explained as "social interaction", "participation in common groups-social networks in society", "social stability", "sense of pride/ commitment to the place", "safety and security".
MCKENZIE	Crafting thriving and habitable neighborhoods involves both structured and spontaneous methods, mechanisms, frameworks, and connections. The promotion of social sustainability transpires when the potential of forthcoming generations is duly accounted for and supported.
MAK VE PEACOCK	Social sustainability is to maintain and improve the well-being of present and future generations.
RAPOPORT	Spatial formations in different cultures are associated with cultural life.
HILLIER&HANSON	Space is not only the product of society, but society is also the product of space.
ASPINALL, CUKIER&DOBERSTEIN	The evaluations to be made about the quality of life form a sustainable society.
SANOFF	Spatial organizations, which are realized through the establishment and preservation of the balance between the human and the living environment, must contain values oriented to the wishes and needs of the user.
TRANCIK&MANEWA	It is the design and use of spaces to serve the desired purpose in social life.
SACHS	It is based on the values of equality and democracy and is the effective distribution of all human rights (political, economic, social and cultural)
POLESE&STREN	Development in harmony with the development of society is an element that promotes an environment that helps the entire population to live together harmoniously with improvements in the quality of life of culturally and socially diverse groups.

DAVIDSON&WILSON Sustaining and enhancing the welfare of present and upcoming generations involves a cultural framework where the favorable elements of diverse cultures are recognized and upheld.

COLONTOINO It encompasses all endeavors within the primary thematic domains that address the societal aspects of individuals and communities, spanning from enhancing capabilities and fostering expertise to addressing disparities in the environment and spatial context.

CHAN&LEE Urban advancements entail crafting a balanced habitat, mitigating societal disparities and fragmentation, and enhancing overall life quality.

OMANN&SPANGENBERG It is the right of every individual to actively participate in society.

CHIU Termed as the enhancement of individual welfare and the just allocation of resources, this endeavor entails mitigating social marginalization and harmful strife that hinge on specific societal interactions, customs, frameworks, and principles embodying the social thresholds and confines of progress, necessitating assessment within the framework of environmental durability.

EMMELHANZ&ADAMS It includes the concepts of "diversity, philanthropy, health and safety and human rights".

HUTCHINS&SUTHERLAND A socially sustainable society is correct, fair, inclusive and democratic. A socially sustainable society ensures a good quality of life for current and future generations.

GOMAA&SAKR It is the improvement of society and social development that meets its needs.

JUAN People should be able to feel comfortable, healthy and safe in their homes and in the built environment. This situation has been defined as "ensuring optimal conditions".

YUNG, CHAN, & XU The concept is the desired goal because social sustainability is a process and the continuity of this process is in question in order to ensure it.

MOLDAN Social sustainability mandates safeguarding the cohesion of society and the capacity to collaborate towards shared objectives. It necessitates catering to personal requisites like physical health, mental well-being, nourishment, shelter, learning, and artistic manifestation.

VALLANCE	The durability of social sustainability is intertwined with the persistence of social and cultural preferences, traits, and the environment as they are upheld across time.
ÇAHANTİMUR	Aiming for people to live a quality life for today and tomorrow; It is the satisfaction of basic human needs.
BERKELEY	It is about the quality of life of individuals now and in the future.
UNITED NATIONS	It can be achieved by eliminating poverty in the construction of sustainable societies and environments.
WACOSS	The characteristics that should be possessed by socially sustainable communities are reflected in five principles: equality, diversity, interconnectedness, quality of life, democracy and governance.
PARTRIDGE	it is a quality of life, equality (social justice), inclusiveness, accessibility, future-orientation, and participatory process.
STIFTUNG	This notion encompasses Fundamental necessities, Societal safety nets, Equitable avenues for engagement within a democratic community, and fostering prospects for societal innovation.
THIN	It is social justice, solidarity, participation, security.
EGAN	It is stated that in the measurement of social sustainability, the preference is to use both qualitative and quantitative methods in addition to statistical methods. In the evaluation processes, it is emphasized that qualities such as accurate assessment, sound decision-making, communication skills, leadership, etc., come to the forefront.
BIART	The concept of social sustainability aims to anticipate and develop solutions for potential challenges that may arise while creating a harmonious and actively functioning society, with minimal changes to the social structure, in the long-term development strategies of communities.
ASSEFA&FROSTELL	It argues that while economic and environmental sustainability form the purpose of sustainable development, social sustainability is the expected ultimate point of sustainable development.
HOLDEN	It states that social sustainability is an urban development process that fosters harmonious social relationships,

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

enhances social integration, and improves living conditions for the entire society.

VALLANCE, PERKINS & DIXON & It states that neglecting social sustainability data leads to the development of uncertain and inadequate theories.

3. CONCLUSION

The organization of social interactions among people and the nature of these interactions are shaped by the constructed surroundings. Simultaneously, the constructed environment assumes a crucial function in either facilitating or impeding the advancement of activities within societal life. Within this dual relationship, the interplay between societal existence and the constructed environment accentuates the significance of the built environment and its spatial attributes concerning social sustainability. At this juncture, the attempt to define social sustainability through various methods across different disciplines has led to a confusion in the literature due to the absence of these distinct definitions coexisting. In this study, the compilation of articles and authors with a high number of citations among all these definitions underscores its significance. Because human beings are at the center of architecture, it is possible to directly or indirectly relate many topics addressed in the architectural design process to social sustainability. In this regard, examining and comprehending the definitions derived from the literature regarding social sustainability will shed light on all future endeavors falling under the realm of architecture and social sustainability.

ABSTRACT

Health tourism, which has existed throughout history, plays a vital role in all sorts of tourism. These treatments and leisure trips have also contributed to the expansion of health tourism. 'Thermal tourism,' which is part of health tourism, arose as a result of people's search for alternative treatment methods for health problems, their desire to spend time away from daily life, and the need to seek peace by getting away from city problems and being alone with nature. This sort of tourism, which makes use of natural resources for health purposes, has resulted in the establishment of several facilities to protect or improve people's mental and physical health. Thermal hotels in Afyon province, which are rich in thermal water potential, are discussed in this paper. The study's goal is to evaluate and quantify the design impact of landscape regions on thermal accommodation facilities. The four largest hotels in terms of area were considered within the scope of the study. The hotels were rated using six primary criteria based on information acquired from on-site observations and interviews. The entrance section, parking area, recreation areas, urban equipment, planting and structural design are examples of these. In the conclusion section, numerous ideas are made on how these unfavorable landscape locations might be used more efficiently and how the design can be improved while keeping the connection between health and landscape in mind.

Keywords: Thermal Tourism, Thermal Hotels, Afyonkarahisar, Landscape Design.

1. INTRODUCTION

Tourism's etymological root is the Latin word "tornus" which means "to depart from some location or point and return to the same location or point again" (Oruç, 2004; Şemşimoğlu Erhan, 2010). Tourism is defined as "all of the economic, cultural and technical measures and studies carried out to attract tourists to a country or region, a trip made for these purposes such as rest, entertainment, seeing and getting to know" in the Turkish Language Association dictionary (Turkish Language Institute, 1998).

The tourism industry continues to emerge as a popular industry around the world. The rise in human living standards and social rights, as well as the monotony and stress of daily life, alter people's expectations of tourism activities, as well as their preferences and desires for tourism. As a result, people are increasingly resorting to other kinds of tourism in addition to sea-sand-

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

sun tourism. Health is clearly an important component that draws people to tourism (Erdoğan & Akınoğlu, 2008).

Traveling to places other than one's current location to safeguard or improve one's mental and physical health is often referred to as health tourism. T.C. The Ministry of Culture and Tourism (KTB) defines health tourism as "a type of tourism that allows the growth of health institutions by using international patient potential with those in need of physical therapy and rehabilitation" (Buldukoğlu, 2014).

The Turkey Health Tourism Board (SATÜRK) assessed health tourism under four broad categories. Thermal health tourism, medical tourism, elderly tourism (3rd age tourism) and disability tourism are examples of these (Zararsız, 2022).

Thermal tourism, which is part of health tourism, is a type of tourism that tries to improve deteriorating health or further improve health by visiting facilities developed in places where thermal water flows and using various thermal applications and supportive therapies. Some physical disorders are cured and people are made to feel more psychologically relaxed in mineral spring, thermal, hot spring, and similar facilities (Buldukoğlu, 2014).

Turkey lies on a significant geothermal belt in this direction. Combining thermal tourism with other types of tourism and making it available to visitors raises demand and interest in this sort of tourism. This study focused on Afyonkarahisar province, which has significant thermal resources in our country. The study is aimed at examining thermal tourism facilities, which play a key role in tourism and to quantify their contribution to accommodation facilities by analyzing landscape areas in terms of design.

1.1. Thermal tourism and Turkey

Thermal tourism, as defined by the Ministry of Culture and Tourism, is "a type of tourism that occurs with the use of thermal waters for entertainment and recreation purposes, as well as cure (treatment) applications made by combining various types of methods such as thermo mineral water bathing, drinking, inhalation, mud bathing, as well as support treatments such as climate cure, physical therapy, rehabilitation, exercise, psychotherapy, diet" (Bucak & Özkaya, 2013). Thermal tourism applications are classified based on the needs of the visitors. Physiotherapy, thalassotherapy, balneotherapy, inhalation applications, climatotherapy, cure, spa treatment, uvalism and hydrotherapy are some examples (Coşkun, 2022).

People all over the world, including our own country, are becoming increasingly interested in thermal tourism in order to alleviate the health problems caused by city living, as well as to rest and refresh themselves (Mercan, 2006). Thermal tourism is now popular all over the world, particularly in Southern, Central and Eastern Europe, Asia (The Middle East, Japan, China, and the Turkic Republics), South America (Argentina, Mexico and Colombia) and North Africa (Morocco and Tunisia) (Bucak & Özkaya, 2013). Our country ranks first in Europe in terms of resource potential and third in terms of spa applications and it is one of the top seven countries in the world in terms of geothermal resource richness and potential (Şemşimoğlu Erhan, 2010). In Turkey, there are about 520 operating spa facilities associated with the Ministry of Health that utilize geothermal resources (MAPEG, 2022) (Figure 1).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 1. Thermal tourism facilities in Turkey, including cities with hot springs and an estimate of the number of facilities (“Türkiye Kaplıcaları Portalı”, n.d.)

According to KTB 2022 figures, the total number of visitors to accommodation facilities with tourism operation certificates in our nation is 2.420.791. Figure 2 shows that 25,60% are foreigners and 74,40% are locals. Based on the data, it can be concluded that the facilities are primarily preferred by domestic tourists. After reviewing the nation and facility type titles, it was discovered that thermal facilities garnered the most attention from Europe.

Figure 2. Arrival numbers in 2022 by facility types in Turkey (KTB, 2022)

When thermal tourism statistics for 2022 were analyzed, it was discovered that the average stay in a thermal hotel was 2,04 days for foreigners and 2,06 days for locals; in thermal resorts, it was 2,6 days for foreigners and 2,23 days for locals. When the total is taken into account, thermal springs come in first with 2,38 days (Figure 3).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 3. The average length of stay in 2022 according to facility types in Turkey (KTB, 2022)

2. MATERIAL and METHOD

Afyonkarahisar is located in the Aegean Region's Inner Western Anatolia section, west of the Anatolian Peninsula, connecting the east to the west and the north to the south, and is bordered by the provinces of Konya in the east, Burdur in the south, Isparta in the southeast, Uşak in the west, Eskişehir in the north and Kütahya in the northwest (Figure 4) (Aydıngöz, 2005).

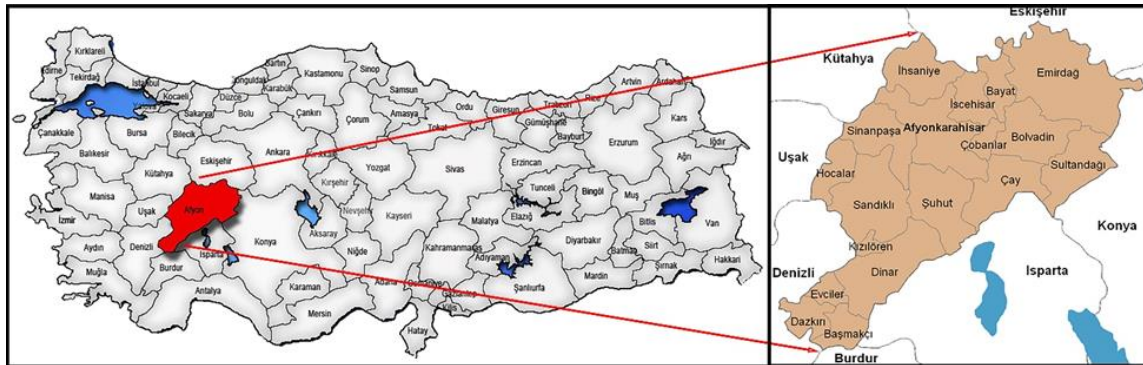

Figure 4. Location of Afyonkarahisar province

Afyonkarahisar province is part of the Phrygia Thermal Tourism Region, one of four regions covering 17 provinces that were designated as Thermal Tourism Centers by the KTB in 2007. Afyonkarahisar is home to four of the 34 thermal tourism centers established by the same decision (Sandıkçı et al., 2013). In terms of thermal tourism, some districts around the province stand out. The Central District, İhsaniye, Sandıklı and Bolvadin districts are among them. Given the locations of the areas under question, it is clear that the benefits of road transportation are significant (Taş, 2012).

Within the scope of the study, thermal facilities in Afyonkarahisar province were studied and four thermal facilities were chosen based on their magnitude in terms of landscape areas. These are: Akrones Thermal SPA Hotel, Grand Özgül Thermal Holiday Village, Korel Thermal Resort Clinic & SPA and NG Afyon Thermal Hotel. The location and area sizes of the facilities considered are shown in Table 1 below.

TeMALab
Department of Civil, Building and Environmental Engineering

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Table 1. Locations and area sizes of selected facilities

No	Hotel Names	Location	Area Size (m ²)
1	Akrones Thermal SPA Hotel	Merkez	64.470
2	Grand Özgül Thermal Holiday	İhsaniye	112.080
3	Korel Thermal Resort Clinic & SPA	Merkez	87.660
4	NG Afyon Thermal Hotel	Merkez	45.730

Obtaining research data; It was completed as a result of collecting important information through a literature study, on-site observation, photographing and conducting necessary interviews. The chosen facilities were assessed under six major areas. These are; the entrance section, the parking area, the recreation areas, the urban equipment and the planting and structural design. The landscape designs of the facilities evaluated under these topics were given in the study, their appropriateness was examined and numerous suggestions on how they could be improved were made.

3. RESULTS and DISCUSSION

3.1. Akrones Thermal SPA Hotel

The Akrones Thermal SPA Hotel is located 10 kilometers from the town of Afyonkarahisar, 45 kilometers from Zafer Airport and 90 kilometers from Uşak Airport. There are 317 rooms and 750 beds in the hotel. The hotel's garden area is 20.800 m². The SPA area at the hotel is 16.000 m². There are also three outdoor and six indoor swimming pools in the hotel ("Basın", n.d.) (Figure 5).

Figure 5. General and plan views of the Akrones Thermal SPA Hotel ("Akrones Hotel", n.d.; "Google", n.d.a)

The Entrance Section: The hotel has only one entrance for vehicles and pedestrians. There is a security booth at the entrance (Figure 6). When examined in terms of landscape design, it was observed that it did not have an impressive and adequate landscape design.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 6. The entrance section of the Akrones Thermal SPA Hotel

Parking Area: The hotel meets the need for open and closed parking areas, but an examination of the open parking area reveals that the planting design is insufficient (Figure 7).

Figure 7. Parking area at Akrones Thermal SPA Hotel

Recreation Areas: The facility area includes an aquapark, children's swimming area, swimming pool, thermal pool, chess area, and children's playground (Figure 8). A walking track is located at the back of the facility, in addition to the seating places.

Figure 8. Children's pool and playground at Akrones Thermal SPA Hotel

Urban Equipment: Two types of lighting are used in the hotel: low and high. There are open-top seating areas for incoming guests. A single type of garbage bin was used in the area. Rattan material was preferred in outdoor seating elements and is suitable for climatic conditions (Figure 9).

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 9. Akrones Thermal SPA Hotel urban equipment

Planting Design: Plant species that could adapt to the region's climatic circumstances were preferred among those used. *Juniperus sabina* (savin) is the most popular species in the area (Figure 10).

Figure 10. Akrones Thermal SPA Hotel planting design

Structural Design: There is an ornamental pool in the front and backyard. In the backyard, seating areas were built with terracing techniques. Informal design is dominant in the area. Different pavement types were used in the area (Figure 11). Rubber flooring is preferred in the children's playground. There are no accessible design solutions in the area.

Figure 11. Akrones Thermal SPA Hotel structural design

3.2. Grand Özgül Thermal Holiday Village

Grand Özgül Thermal Holiday Village is 20 km from Afyonkarahisar city center, 40 km from Zafer Airport and 15 km from İhsaniye centre. It has 606 rooms, including 489 suites, 92 deluxe suites, 25 luxury villas and 1 VIP villa and a capacity of 2.500 beds. The hotel has a social

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

facility area of 20.000 m² (Figure 12). There is a SPA with a total usage area of 15.560 m², 2 outdoor and 2 indoor swimming pools, 2 indoor entertainment pools and an aquapark. The hotel also has 2 cave pools (Damlataş Cave) and two thermal pools ("Hakkımızda", n.d.).

Figure 12. General and plan views of the Grand Özgül Thermal Holiday Village ("Grand Özgül Termal Tatil Köyü", n.d.; "Google", n.d.b)

The Entrance Section: There is only one entry to the hotel for both automobiles and pedestrians. At the entrance, there is a security booth (Figure 13). An aesthetic appearance could not be achieved in terms of landscape design in the entrance section.

Figure 13. The entrance section of the Grand Özgül Thermal Holiday Village

Parking Area: At the hotel, only outdoor parking is provided. Each block has its own parking lot. Parking lots are insufficient when it comes to planting design (Figure 14).

Figure 14. Parking lot at Grand Özgül Thermal Holiday Village

Recreation Areas: A children's playground, a small zoo, a multi-purpose field (basketball-volleyball-tennis), a football field, a trampoline, a sports field, and an entertainment area are all available at the hotel. The football field ground is in reasonable condition, but the multi-purpose

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

field ground is in bad condition. The materials utilized in children's playgrounds are outdated and unsuitable (Figure 15).

Figure 15. Recreational areas at Grand Özgül Thermal Holiday Village

Urban Equipment: In the area, three forms of illumination were used: lighting installed on trees, low lighting, and high lighting. The open and covered seating areas have been designed in a natural style. Swings can be found in some areas of the area. For garbage cans, a single type has been chosen (Figure 16).

Figure 16. Grand Özgül Thermal Holiday Village urban equipment

Planting Design: Planting design is not given much consideration in the area. On the roadway, tall trees are followed by shrubs and ground coverings (Figure 17).

Figure 17. Grand Özgül Thermal Holiday Village planting design

Structural Design: The landscape in the area is sloped and hilly. The facility has one ornamental pool in the centre area and two ornamental pools in the back. The location has observation

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

terraces as well as bridges. In ornamental ponds, artificial rock is used. Different pavement types were used in the area (Figure 18).

Figure 18. Grand Özgül Thermal Holiday Village structural design

3.3. Korel Thermal Resort Clinic & SPA

Korel Thermal Resort Clinic & SPA is located 13 kilometers from the town of Afyonkarahisar and 45 kilometers from Zafer Airport. The facility's landscape area is 31.140 m². There are 329 rooms and 1.000 beds at the facility. There are also two outdoor and four indoor swimming pools, four thermal pools for spa treatments and a 4.000 m² health complex with an SPA and a clinic ("Kurumsal", n.d.) (Figure 19).

Figure 19. General and plan views of the Korel Thermal Resort Clinic & SPA ("Korel Thermal Resort Clinic & SPA", n.d.; "Google", n.d.c)

The Entrance Section: The hotel has a single vehicle and pedestrian entrance. At the entrance, there is a security booth. In terms of landscape design, the entrance part is insufficient (Figure 20).

Figure 20. The entrance section of the Korel Thermal Resort Clinic & SPA

TeMALab
 Department of Civil, Building and Environmental Engineering
 University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

Parking Area: It offers an open parking lot for 200 vehicles, a helipad, and an electric vehicle charging station. There is no indoor parking (Figure 21). Even though the helipad is outdated, it is critical to include both the runway and the charging station for electric vehicles in order to keep up with advances and incorporate them into the design.

Figure 21. Korel Thermal Resort Clinic & SPA parking area and helipad

Recreation Areas: A children's playground and two swimming pools are available at the venue. There is bicycle access to the facility, and free bicycle use is planned for returning clients (Figure 22).

Figure 22. Korel Thermal Resort Clinic & SPA bicycle area and children's playground

Urban Equipment: There were two types of illumination used: low and high. The facility made use of a variety of garbage cans. The space includes three pergolas and different sitting features (Figure 23).

Figure 23. Korel Thermal Resort Clinic & SPA urban equipment

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Planting Design: In terms of planting landscape design, the area is insufficient. Trees are arranged irregularly. Dolomite stone has been used to create a variety of designs (Figure 24).

Figure 24. Korel Thermal Resort Clinic & SPA planting design

Structural Design: There is an ornamental pool in the front garden of the hotel. Different pavement types were used in the area. The same path is used for hiking and cycling. The backyard of the hotel is accessed by stairs. However, there is no ramp solution. There are no accessible design solutions in the area (Figure 25).

Figure 25. Korel Thermal Resort Clinic & SPA structural design

3.4. NG Afyon Thermal Hotel

At the intersection of all routes, NG Afyon is 45 kilometers from Zafer Airport and 90 kilometers from Uşak Airport. The facility's landscape area is 11.480 m². The complex has a total of 16 pools. 13 of these pools are indoor (seven have thermal water features) and three are outdoor (one has a thermal water feature) ("Aliva SPA", n.d.) (Figure 26).

Figure 26. General and plan views of the NG Afyon Thermal Hotel ("NG Afyon Wellness & Convention Afyon Türkiye", n.d.; "Google", n.d.d)

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

The Entrance Section: The hotel has a single vehicle and pedestrian entrance. At the entrance, there is a security booth. In terms of landscape design, the entrance part is insufficient (Figure 27).

Figure 27. NG Afyon Thermal Hotel entrance section

Parking Area: It contains a total of 1,800 open parking spaces. The parking lot and swimming pool area were separated by vegetative screening (Figure 28).

Figure 28. NG Afyon Thermal Hotel parking area

Recreation Areas: The facility has three fields: a fire pit for nine people, a coloring house for children, a multi-purpose field (basketball-volleyball) and two tennis courts (Figure 29).

Figure 29. Recreational areas at NG Afyon Thermal Hotel

Urban Equipment: A standardized waste can was utilized. Bird nests were built in the trees for the local birds. The walking trails are accompanied by sculptures, although their designs and the purpose of the artistic objects are unknown (Figure 30).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 30. NG Afyon Thermal Hotel urban equipment

Planting Design: The ornamental pools in the area were decommissioned and used in the plant composition, which did not seem appealing in terms of design. In general, vegetal screening was preferred to separate the spaces. The entry area was made more inviting by the use of *Drosanthemum floribundum* (persian carpet) (Figure 31).

Figure 31. NG Afyon Thermal Hotel planting design

Structural Design: There is an ornamental pool only in the central part of the hotel. Different pavement types were used in the area (Figure 32). There are no designated walking paths for individuals who wish to walk. The hotel's entryway is slanted, although the rest of the property is flat. For the disabled, there is a ramp at the hotel's entrance.

Figure 32. NG Afyon Thermal Hotel structural design

4. Conclusions and Recommendations

In this study, four facilities in the Afyon town were analyzed and rated based on six primary criteria: Akrones Thermal SPA Hotel, Grand Özgül Thermal Holiday Village, Korel Thermal

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

- The entrances to all facilities are controlled. However, there are no attractive landscaping arrangements that will emphasize the entry and appeal to the eye, particularly at facility and building entrances.
- When examining the parking areas of the facilities, it is clear that the majority of them do not offer indoor parking. It has been discovered that at facilities with open parking lots, plant species that shade the vehicles are not utilized and plant design is inadequate.
- When the facilities' recreational facilities were reviewed, it was discovered that sports fields were not available in every facility and those that were available were limited to a few fields. There are also no walking trails in the facility, which would allow for integration with nature. Aside from these functions, there were no designs of distinct recreation spaces that would provide a human-nature approach in the facilities.
- Although the urban equipment of the facilities is found to be adequate, the most significant problem identified is that it is outdated and neglected. It has been determined in some facilities that there is no compatibility between the equipment and that acceptable materials are not utilized. Water elements were not used in every facility, although they were included in the plant design in some. The various water design components were not widely implemented in the facilities. There are very few artistic objects used and those that are available are incompatible with the concept.
- When the plant designs of the facilities are examined, it is discovered that, while plants native to the area are used, the size, form, color and texture characteristics of the plants are ignored and aesthetically appropriate plant species are not used in the designs. Another essential aspect to note is that the plant design in the facilities is not taken into account as a whole, but is just glossed over with different layouts at different places.
- When the structural designs of the facilities were evaluated, it was discovered that the floor paving had a lot of variety, but their harmony and combinations were not adequate. Some paving was found to be deteriorated. A comprehensive approach to structural design has not been seen as much as in vegetative design. Most facilities have not considered the concept of barrier-free design.

Landscape designs in thermal tourism facilities must be enhanced to address the inadequacies identified in these findings. Furthermore, thermal tourism is practiced not only to maintain and promote physical health, but also to protect and improve mental health. At this stage, the visitors' goal is to enjoy a nice and quality time while also making time for themselves by easing the fatigue of working life. When examined from this angle, the landscape design of thermal tourism facilities was found to be more structure-oriented. When the designs are inspected, it is clear that the region was not taken into account as a whole and that the landscape design was added later and was solely utilized to cover the gaps left by the structural design.

Thermal tourism started as an alternative to coastal and marine tourism, which are referred to as the "3S" in world tourism ("Sun", "Sand" and "Sea"). When the landscape designs of the two types of tourism are compared, it is clear that the design approach in thermal tourism facilities is weaker and more irresponsible.

However, landscape design is critical in these contexts where mental and physical health are prioritized. Landscape areas have a major impact on overall mental health, stress and depression

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

reduction and cognitive function improvement. As a result, landscape designs that connect human beings to nature, encourage exercise and socialization must be incorporated into these institutions.

ABSTRACT

Urban landscape is a discipline that deals with the planning, organization, and design of outdoor spaces in urban areas. Urban landscaping aims to improve the quality of life of urban dwellers by ensuring environmental sustainability. Urban landscape applications can play an effective role in ensuring the interaction of people with nature in cities, the sustainability of ecosystem services, and the protection of natural resources in cities. This study aims to conduct a bibliometric analysis of scientific studies on the urban landscape, which is of great importance in terms of the physical and psychological health of urban people and environmental sustainability in today's rapidly increasing urbanization. Bibliometric analysis enables to reveal the production of knowledge by examining various characteristics of scientific research in a particular field. This research, it was tried to determine the distribution of scientific studies on the concept of the urban landscape by years, authors, types of publications, in which countries the studies on the concept were mostly conducted, frequently used keywords, areas related to the concept, and other prominent details through bibliometric analysis. The Scopus database was determined as the study population. In the database, 1359 scientific documents were utilized. As a result of the study, it was determined that the studies on urban landscape started in 1968 and that there has been an increasing trend since 2016, 145 scientific studies were conducted in 2022, the most studies were produced at Arizona State University in the United States of America, and the keywords urban planning, urban area, land use were frequently used in the studies.

Keywords: Urban Landscape, Bibliometric Analysis, Landscape Architecture.

1. INTRODUCTION

It is known that cities, where most of the world's population lives, are growing and developing rapidly. changes and transformations are observed in urban areas due to growth and development. As a result of the aforementioned change and transformation process, the urban landscape is extremely important in terms of increasing the quality of life in urban areas and ensuring sustainability. Urban landscape is a multidimensional discipline that deals with the organization and design of the urban environment and includes many factors such as environmental sustainability, social welfare, aesthetic values, and protection of natural resources. The concept of urban landscape refers to the composition of the landscape in the city, a conscious order of the urban area. In the concept of urban landscape, the relationship of the existing structures in the urban area with each other and with unstructured areas should be considered as a whole (Karaman, 1995). Along with the physical structure, the socio-cultural

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

structure also has an important effect on the formation of the urban landscape (Çelik and Yazgan, 2007). In this context, bibliometric analysis of the research on the concept of urban landscape will help us to understand the development of the subject in question and to determine the directions of future studies. With this analysis, it will be possible to reveal how the urban landscape has developed, the distribution of scientific studies by years, in which countries the studies are mostly conducted, frequently used keywords, which disciplines contribute to the subject, and what other prominent details are.

This study aims to evaluate important topics, authors, publications, and citations in the field of Urban Landscape to reveal the essence, emphasis, evolution, and direction of scientific research in this field.

It is thought that this study will contribute to our understanding of the importance of the concept of urban landscape today and the future directions of scientific studies in this field, and it can be an important resource for researchers, planners, and decision-makers who want to focus on research in this field in the future.

Urban Landscape

In parallel with the rapid increase in the world population, it is known that population and physical growth in urban areas are increasing at the same rate. As a result of this increase, it is becoming increasingly difficult to create sustainable living spaces for cities. In the face of these problems, it becomes imperative to develop new perspectives and different approaches in planning and design for sustainable cities. One of these approaches is the urban landscape approach, which is known to provide many benefits to the city through urban ecosystems (Tezgör, 2021).

The urban landscape is "a heterogeneous combination of structures and other areas in the city and consists of pieces of land that can be distinguished by different usage and management models. The urban landscape reflects the urban fabric: green spaces at the building level, such as balconies, green roofs, and vertical gardens; green spaces close to buildings, such as residential gardens, playgrounds, parks, gardens of institutional buildings, planted areas on streets and avenues, cemeteries, sports fields, and hobby gardens; and more open green spaces, such as agricultural lands and gardens, forests, wastelands, quarries and dunes (Braquinho et al., 2015).

Urban landscape determines the relationship between the structures and unbuilt areas in the city as a whole, the structures with different characteristics in form, size, color, and form, and their organization (Çelik & Yazgan, 2007).

Urban landscape is "a socio-ecological system consisting of ecosystems shaped by natural, cultural, and social processes together" (Andersson, 2006). In urban landscape design, living and non-living materials as well as the elements that make up the city identity are taken into consideration when designing livable spaces to help preserve the city identity and transmit the identity from the past to future generations (Çelik & Yazgan, 2007).

Urban landscape deals with the design, planning, and management of built and open spaces in cities, taking into account environmental, aesthetic, social, cultural, and economic sustainability, and includes design and organization processes to make urban areas more livable, more functional and more attractive by combining natural and man-made elements. Urban landscape plays an effective role in protecting the physical and mental health of people as well

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

as environmental resources. In line with these definitions, urban landscape is a conceptually and practically complex, multidisciplinary field and the scope of scientific studies in this field is constantly expanding.

2. METHOD

This study aims to conduct a bibliometric analysis of scientific studies conducted within the scope of the concept of urban landscape. Bibliometric analysis is a method used to examine the development and trend in academic literature on a particular topic or concept. In bibliometric analysis, certain characteristics of scientific documents such as authors, journal, subject, and publication information are analyzed quantitatively (Al & Tonta, 2004; Yalçın, 2010; Ulu & Akdağ, 2015; Yılmaz, 2017). Bibliometric research is based on analyzing certain characteristics of the content of documents or publications and obtaining various findings on scientific communication (Al & Coştur, 2007).

In this study, the Scopus database was determined as the study population, and 1359 scientific documents between 1968 and 2022 were utilized. In this study, "R" software was used to perform bibliometric analysis. Through bibliometric analysis, it was tried to determine the distribution of scientific studies on the concept of urban landscape according to years, authors, types of publications, in which countries the studies on the concept were mostly conducted, frequently used keywords, areas related to the concept and other prominent details.

3. FINDINGS and DISCUSSION

Within the scope the study, it is aimed to examine the studies on urban landscape design holistically by bibliometric analysis method. The findings obtained as a result of the study are given under headings.

General Status of Urban Landscape Studies

General information about scientific publications on the concept of urban landscape is given in Table 1.

Table 1. General information on scientific research published in Scopus data source within the framework of urban landscape

Definition	Results
Basic Information About Scientific Articles Published In Urban Landscapes	
Time range of scientific articles published in the urban landscape	1968 - 2023
Resources within the scope of urban landscape (Journals, Books, etc.)	741
Documents published within the scope of the urban landscape	1359
The annual growth rate of publications on urban landscape	7,45
The average age of documents in the urban landscape	8,79

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

Average citation per document for urban landscape	14,99
Document Contents	
Keywords	6829
Authors' Keywords	4011
Authors	
Number of authors publishing within the scope of urban landscape	3861
Number of single-authored papers on urban landscape	252
Collaboration With Authors	
Single-authored documents in the context of urban landscape	276
Co-authors for the document in the context of urban landscape (%)	3,3
International co-authors in urban landscape (%)	11,99
Document Types	
Article	906
Book chapter	83
Proceedings book	319
Review article	34
Book	9
Note	3
Correction	2
Editorial	2
Short survey	1

According to Table 1, it is seen that scientific studies on urban landscapes started to be included in the Scopus database in 1968. It is seen that these studies consist of 906 articles, 83 book chapters, 319 articles in proceedings, 34 review articles, 9 books, 3 notes, 2 corrections, 2 editorials, and 1 short survey.

Distribution of Scientific Studies on the Concept of Urban Landscape by Years

The distribution of scientific studies conducted within the scope of the urban landscape concept by years is given in Figure 1

TeMALab
 Department of Civil, Building and Environmental Engineering
 University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

Figure 1. Distribution of scientific studies produced in the field of urban landscape by years

According to Figure 1, it is revealed that the studies on the subject were first produced in 1968, the number of studies was limited until 2004, increased since 2005, and has shown a continuous and rapid increase since 2016. In 2022, the decrease in the number of studies is thought to be due to the indexation period of the scientific studies published within the scope of the subject in the Scopus database.

Keywords Used in Scientific Studies Published in the Field of Urban Landscape

The keyword cloud created according to the frequency of use of keywords used in scientific studies in the field of urban landscape is given in Figure 2. The frequency amounts of the keywords used are given in Table 2, the distribution of keywords according to years is given in Figure 3, and the keyword network is given in Figure 4.

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Table 2. Frequency use of keywords

Word	Frequency
Urban Planning	183
Urban Area	177
Landuse	149
United States	129
Landscaping	124
Article	123
Sustainable development	110
Urbanization	80
China	77
Water Quality	74

Figure 2. Keyword Cloud

When Figure 2 and Table 2 are examined, it is seen that the most frequently used keywords in the studies in the field of urban landscape are "urban planning" (183), "urban area" (177), "land use" (149), "united states" (129), "landscaping" (124), "article" (123), "sustainable development" (110), urbanization (80), China (77), water quality (74).

Figure 3. Distribution of keywords by years

When the graph of the distribution of keywords by years is examined, it is seen that the words "urban planning", "landscape", "urban area", "land use", and "sustainable development" are mostly used in scientific studies conducted in recent years.

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

When Table 3 is examined, it is seen that the articles within the scope of the subject are frequently produced from Arizona State University and University of Florida institutions located in the United States of America. It is possible to see in Figure 5 that the number of scientific articles produced in these institutions has increased with increasing momentum since 2002.

Sources and Temporal Distribution of Scientific Documents Produced within the Scope of Urban Landscape according to Frequency of Publication

The top ten publication sources that frequently produce scientific articles related to the urban landscape area are given in Table 4 according to the frequency of scientific articles published and the graph of the production distribution of publication sources over time is given in Figure 6.

Table 4. Top ten publication sources that frequently produce scientific articles and the number of production

Source	Frequency
Acta Horticulturae	56
Top Conference Series: Earth And Environmental Science	44
Landscape And Urban Planning	33
Urban Forestry And Urban Greening	32
Iop Conference Series: Materials Science And Engineering	27
Sustainability (Switzerland)	25
Urban Ecosystems	21
E3s Web Of Conferences	19
Environmental Management	13
Lecture Notes in Civil Engineering	11

Figure 6. Production distribution of publication sources over time

It can be said that "Acta Horticulture", "Top Conference Series: Earth And Environmental Science", "Landscape and Urban Planning" and "Landscape and Urban Planning" are the most frequent publications and the frequency of production has been on increasing trend since 2003.

Researchers Producing Scientific Publications on the Scope of Urban Landscape, Number of Articles Published, and Most Cited Works

The number of publications of the researchers who produced the highest number of publications within the scope of the subject is given in Table 5, the frequency of production of the authors over time is given in Table 6, and the most cited publications on a global scale and the source of their publication are given in Table 7.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Table 5. Authors and number of publications

Author	Number of Articles
Kelli L. LARSON	14
Na NA (Editör, Urban Space)	14
Jiachen LI	10
Liu XINGJIAN	9
Sharon J. HALL	8
Susannah B. LERMAN	8
Junyi ZHANG	8
Patricia GOBER	7
Ye LI	7
Zhichao LI	7

Table 6. Authors and frequency of publication production

Authors	Frequency	Year
Kelli L. LARSON	4	2020
Patricia GOBER	3	2010
Sharon J. HALL	3	2020
Jiachen LI	3	2018
Na NA (Editör, Urban Space)	3	2013
Patricia GOBER	2	2007
Ye LI	2	2010
Kelli L. LARSON	2	2019
Kelli L. LARSON	2	2021
Kelli L. LARSON	2	2022

When the table is examined, it is seen that most publications within the scope of the subject belong to Larso and Na Na, and the frequency of publication production belongs to Larsona, which had 4 publications in 2020.

Table 7. Information on the most cited publications in the global dimension

Author	Publication Date	Publication Source	Access Number (DOI)	Number of Citation

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

It is seen in the Table that the highest number of citations (564) belongs to the publication titled "Buffer Zone versus Whole Catchment Approaches to Studying Land Use Impact on River Water Quality" published by Sliva L. in Water Research in 2001.

Temporal Distribution of Scientific Articles Published in the Scope of Urban Landscape by Countries

The temporal distribution graph of the scientific articles produced within the scope of urban landscape according to the top five countries is given in Figure 7'.

Figure 7. Temporal distribution of article production by country

The top five countries producing scientific publications on the subject are the United States, China, the United Kingdom, Korea, and Brazil. It is seen that the publications within the scope of the subject in the aforementioned countries have entered a rapid increase trend, especially since 2013, and this trend is high in the United States and China.

Keyword, Country, and Publication Source Relationship Status of Scientific Articles Published in the Scope of Urban Landscape

The 3-field diagram of keyword-country-publication source of scientific articles produced within the scope of the urban landscape is given in Figure 8.

Figure 8. Temporal distribution of article production by country

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

When the figure is examined, it is seen that the scientific publications produced within the scope of the subject are frequently published in Landscape and Urban Planning, the publications are frequently produced in the United States, China, and Brazil, and the words "landscaping", "urban ecology", "landscape", "sustainability", "urban" are mostly used as keywords.

4. CONCLUSIONS and RECOMMENDATIONS

This research was conducted to reveal the general situation, essence, emphasis, development and change process, and current importance of scientific studies in the field of the urban landscape and to provide a source for researchers who want to focus on studies in the field in the future, it is possible to say that there have been many studies on the subject until today and that the number and scope of these studies have expanded and developed in recent years. Today, the expansion and development of the scope of the concept in question in line with the increase in urban population and related urbanization and environmental problems in cities can be considered as usual.

When the sources in which urban landscape studies are published are evaluated, it is seen that the mentioned field of study is a multidisciplinary field that is covered by many professional disciplines, especially horticulture, environmental management, landscape and urban planning, urban forestry, material sciences, urban ecosystem, energy and earth sciences, civil engineering.

When the keywords used in the scientific studies published within the scope of the subject and their temporal distribution are examined, it is possible to see that the word "landscaping", which was frequently used in the first years of the studies, has been replaced by the word "urban planning" in recent years, and the words "urban area" and "land use" have been used more frequently in recent years. In this context, it is possible to say that the field of urban landscape has developed over time and is a research area that is frequently studied by sciences related to urbanization and land use.

The fact that Arizona State University, one of the world's leading universities, has produced the most publications on the subject may provide an idea that the subject is quite current and open to development and change.

When the publication with the highest number of references on the urban landscape (Buffer Zone versus Whole Catchment Approaches to Studying Land Use Impact on River Water Quality) is examined, it is seen that the effects of urban land use on water quality are evaluated in the research. In this context, it is possible to say that the urban landscape effect is very important to water quality and has been the subject of many scientific studies in this field.

When the studies of Kelli L. Larson, who has the highest frequency of publication and the highest number of publications within the scope of the subject, are examined, it is seen that the focus is on sustainability, ecosystem processes, social-ecological systems, cities, and water management. These fields of study reveal that the concept of urban landscape has multifaceted effects.

As a result of the bibliometric analysis of scientific studies conducted within the scope of the urban landscape, it has been revealed that urban landscape studies are a very important, effective, open-to-development, multidisciplinary field of study in line with the principle of sustainability in combating environmental problems in our world where urbanization is increasing rapidly. In this context, it is thought that it is of critical importance for researchers from different disciplines to work together in the stages of conducting scientific studies on the

ABSTRACT

Döşemealtı District, one of the important districts of Antalya, is a residential area that has hosted different civilisations throughout history. Döşemealtı District, which has an important position as an accommodation centre thanks to the ancient Döşemealtı Road and Inns, is a settlement where different cultures come together and especially weaving is dominant, where Adalılar (Cyprus Immigrants), Muhajirs (Thessaly Immigrants) and different Yoruk tribes live together. It was named after the road consisting of ancient paving stones laid with 4 meters wide paving stones by the Romans of the Roman Period in the Derbent Strait, which is 2.5-3 km. northeast of Kovanlık Village of Döşemealtı District, where the plain ends and the first elevations of the Taurus Mountains begin and which was one of the roads connecting the cities of Pamphylia and Psidia in ancient times. Döşemealtı region has a very rich potential in terms of cultural heritage such as famous caves (Karain Cave, Kocain Cave, Kızılın Cave, Çarkini Cave), ancient cities, ancient Döşemealtı Strait, water cisterns, caravanserais, protected areas etc. As a result of the increase in migration from villages in the Döşemealtı region and the transformation of villages into neighbourhoods in the urbanisation process, the way of life has undergone rapid change and erosion. Thus, as a result of not giving due importance to cultural heritage values, their functions have started to lose their importance gradually. This study aims to reveal the natural and cultural heritage values and their importance in Döşemealtı Region. In this context, it is to develop suggestions for the protection, development and sustainability of the natural and cultural heritage values of the Döşemealtı region. Thus, it is envisaged to increase the conscious awareness of the relevant stakeholders (managers, decision-makers, institutions, NGOs, local people, tourism agencies, etc.).

Keywords: Döşemealtı Region, Cultural Heritage, Conservation, Sustainability. Antalya.

1. INTRODUCTION

Cultural heritage is a set of all kinds of tangible and intangible assets or values that are related to the past and experiences of a society, define its identity, and carry the characteristics of local and universal values that have survived to the present day with their vital continuity. It includes all the characteristics of the environment that emerged as a result of the interaction between people and places over time (Ünal, 2014; Pelit et al., 2018).

Tangible and intangible values that emerge as a result of the interaction and interaction between human-culture-space and environment are considered cultural heritage value that is vital in the

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

transmission of culture, and the creation and protection of collective memory (Gül & Gül, 2021).

Cultural values or assets include many values such as architectural structures, monuments, beliefs, symbols and traditions specific to the country, region or settlement. These values are generally defined as tangible (archaeological, artistic, architectural structures) and intangible (beliefs, customs, traditions, traditions and customs, etc.) values (Bedate et al., 2004; Metin & Gül, 2017; Gül & Gül, 2021).

The General Conference of the United Nations Educational, Scientific and Cultural Organization meeting in Paris from 17 October to 21 November 1972, at its seventeenth session (UNESCO, 1992-2023). For this Convention, the following are recognised as "cultural heritage" (UNESCO, 1992-2023).

- **Monuments:** architectural works, works of monumental sculpture and painting, elements or structures of an archaeological nature, inscriptions, cave dwellings and combinations of features, which are of outstanding universal value from the point of view of history, art or science;
- **Groups of Buildings:** groups of separate or connected buildings which, because of their architecture, their homogeneity or their place in the landscape, are of outstanding universal value from the point of view of history, art or science;
- **Sites:** works of man or the combined works of nature and man, and areas including archaeological sites which are of outstanding universal value from the historical, aesthetic, ethnological or anthropological point of view.

Cultural and natural heritage is increasingly threatened with extinction, not only due to traditional causes of deterioration but also due to changing social and economic conditions that aggravate the situation with even more egregious cases of damage or destruction (UNESCO, 1992-2023).

Today, the urbanisation process that develops horizontally and vertically, rapidly changing and evolving social, economic and technological processes, differentiating and changing lifestyles change and affect the unique structure of cultural heritage and ultimately lead to cultural erosion and destruction of cultural identity elements (Artun, 2001; Kanlı, 2015; Dikmen & Toruk, 2016).

When rural settlements in Anatolia are examined, rural spaces are shaped by their unique lifestyles and forms, natural and cultural landscape values have diversity and richness in terms of space and identity values that differ from region to region, even in villages located in the same region. Today, the increase in globalisation and urbanisation trends, inadequacy of opportunities in many areas such as social, economic, health, education, etc., and diversification of needs have put rural/local/village settlements under pressure, increased migration to cities, and often led to negative interaction with rural settlements. This situation has led to the change, degeneration or destruction of the local identity and landscape values of rural settlements. The natural and cultural values of rural settlements have turned into artificial spaces for consumption purposes in the context of modernisation and globalisation, just like urban spaces. (Gül et al., 2020a).

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Today, rural areas are losing their local identities and disappearing. For a sustainable cultural heritage, it is necessary to protect the natural and cultural environment without deterioration and to ensure that future generations benefit from all resources as they do today. For this purpose, it is of great importance to inform the relevant stakeholders and raise awareness for the identification and sustainability of cultural heritage values (Seçilmiş & Köz, 2015: 74).

The protection and preservation of local identity depends primarily on local people taking responsibility. Participation of local people should be ensured at every stage of the process in planning and management. To create a local identity, local holistic identity values should be evaluated, core values should be prioritised according to the perceptual level, and the area should be turned into a destination area through image and branding studies (Gül et al., 2019).

Today, tourism is the most important locomotive of economic and socio-cultural development. The planning of cultural tourism routes is of great importance for the protection of cultural heritage values and the utilisation of economic potential (Gül et al., 2020b).

Döşemealtı District, one of the important districts of Antalya, is a residential area that has hosted different civilisations throughout history. Döşemealtı District, which has an important position as an accommodation centre thanks to the ancient Döşemealtı Road and Hans, is a settlement where different cultures come together and especially weaving is dominant, where "Adalılar" (Cyprus Immigrants), "Muhacirler" (Thessaly Immigrants) and different Yörük tribes live together.

It was named after the road consisting of ancient paving stones laid with 4 meters wide paving stones by the Romans of the Roman Period in the Derbent Strait, which is 2.5-3 km. northeast of Kovanlık Village of Döşemealtı District, where the plain ends and the first elevations of the Taurus Mountains begin and which was one of the roads connecting the cities of Pamphylia and Psidia in ancient times (Döşemealtı Belediyesi, 2016).

Döşemealtı region has a very rich potential in terms of cultural heritage, especially famous caves (such as Karain Cave, Kocain Cave, Kızılın Cave, Çarkini Cave), ancient cities, ancient Döşeme Strait, water cisterns, caravanserais, protected areas, etc. (Döşemealtı Belediyesi, 2016).

In Döşemealtı region, the way of life has undergone rapid change and erosion as a result of increased migration from villages, rapid urbanisation process and transformation of villages into neighbourhoods. Thus, as a result of not giving due importance to cultural heritage values, their functions have started to lose their importance gradually.

This study aims to reveal the importance and value of the natural and cultural heritage values and historical processes of Döşemealtı Region. At the same time, it is to develop suggestions for the protection, development and sustainability of natural and cultural heritage values. In addition, it is envisaged to increase the conscious awareness of the relevant stakeholders (managers, decision-makers, institutions, NGOs, local people, tourism agencies, etc.) about the natural and cultural heritage values of Döşemealtı Region.

2. Material and Method

In the research, Döşemealtı Municipality website and other websites related to Döşemealtı were examined. Scientific research and publications on the Döşemealtı region were analysed. As a result of interviews, observations and examinations made with local people in the Döşemealtı

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

region, heritage values were determined as a whole. For this purpose, it has been analysed under 3 main headings (Monuments, Building Groups, and Sites) accepted by Unesco as "cultural heritage".

3. FINDINGS

3.1. Existing Cultural Heritage Values of Döşemealtı Region

Döşemealtı District, which is 12 km. away from Antalya City Centre, is located in the north of Bucak, Konyaaltı in the south, Kepez in the east and Korkuteli in the west. There are 32 neighbourhoods in Döşemealtı District. Its surface area is 673,1 km². Döşemealtı was named after the 4-meter-wide road consisting of ancient paving stones in the Derbent Strait, which was one of the roads connecting the cities of Pamphylia and Psidia in ancient times. It is understood from the inscriptions on the milestones that the ancient Roman road called "Via Sebaste" (also called Alexander Road), which was not exactly determined by whom it was first used, was built by Augustus (Octavius), who was emperor for forty years, especially to fight Cilician pirates. The paved road, which continued to function during the Byzantine, Seljuk and Ottoman periods, was used as a migration route by Yörükler (Yoruks) until recently. For this reason, the local people called the gorge through which the road passes "Döşeme" "Döşeme Boğazı" and the plain under the road "Döşemealtı" (Döşemealtı Belediyesi, 2016).

In the Döşemealtı district, which has a very large area and where nomads with different names and at different times settled at close distances to each other, a mixed cultural structure was formed with the settlement of the Adalılar (Cypriots) and Thessalian immigrants, also known as Muhacirler among the people. According to Prof. Dr. Işın Yalçınkaya, Döşemealtı District, which is a settlement established in the plain near Karain Cave, is one of the oldest settlements in Türkiye.

3.1.1. Caves

In Döşemealtı; there are many caves (Karain Cave, Kocain Cave, Kızılın Cave, Çarkini, Boynuzluin, Öküzini Cave, etc.) which have been identified and are still under research in terms of cultural heritage with their natural life and historical dimension.

a. Karain Cave

Karain cave is located approximately 30 km northwest of Antalya city centre, northeast of the Yağca neighbourhood of Döşemealtı district (Figure 1). It is the most intensively researched Palaeolithic centre of Anatolia. Excavations started in 1946 and continued until 1973. Afterwards, the unexcavated areas were resumed in 1985 under the direction of Prof. Dr. Işın Yalçınkaya (Kartal, 1999).

It is considered to be the only cave in Anatolia where skeletal and dental remains of Neanderthal humans were found and which allowed the Middle Palaeolithic chronology to be established (Yalçınkaya & Özçelik; 2012). It was continuously inhabited by humans from the Lower Palaeolithic period until the Late Roman-Early Byzantine period (Yalçınkaya, 1988) and is the most important cult centre of Meter Orei, which means "Mountain Mother" or "Goddess Sitting in the Mountains" in the Pamphylia Region (Akın, 2016).

b. Kocain Cave

It is located in Hisaradağı / İndağı at an altitude of 1.171 m, about 45 km north of Antalya Province. Kocain Cave is 600 m long, 35 m wide at the entrance, 75 m wide inside and 50-60 m high in some places. In 1990, it was declared a 1st degree Archaeological-Natural Site. There is also a very large cistern dating from the Roman Period inside the Kocain Cave. There are also wall traces of a building complex dating back to the Roman Imperial Age in front of the cave. Inside the cave, near the entrance, on a rather large limestone rock mass suitable for inscription, the names of many "eirenarkhes" and "anteirenarkhes" and their assistants, the diogmites, are carved. A total of 28 inscriptions dedicated by eirenarkhes, anteirenarkhes and diogmites were discovered by the Italian researcher G. Moretti in 1919 and published in 1926. On the inscriptions published by Moretti, it was seen that many inscriptions were published incorrectly and incompletely, which were identified and corrected by Assoc. Prof. Dr Hüseyin Sami Öztürk in the new readings made in 2006 (Öztürk, 2015) (Figure 2 a-b-c).

c

Figure 2. a. View of the cistern from the entrance of Kocain Cave, b. Inscriptions on the rock from the ceiling to the floor, c. Cave interior (Original Photo: Öncü, 28/08/2021).

c. Kızılın Cave

Kızılın Cave is located within the borders of the Yağca neighbourhood of Döşemealtı District of Antalya Province. It is 1.6 kilometres from the centre of Yağca neighbourhood and 3.5 kilometres from Karain settlement. Kızılın is a Grade 1 Natural and Archaeological Site. However, it also falls within the Antalya Düzlerçamı Wildlife Development Area. Excavations were initiated by Professor İsmail Kılıç Kökten in the 1950s (Demirel et al., 2019) (Figure 3).

Figure 3, Kızılın Excavations, (Original Photo: Kartal, 1999)

d. Çarkini Cave

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

It is a natural cave located northwest of Antalya city centre, 1 km northwest of Somaklı Street, Yağca neighbourhood and 2 km south-southwest of Karain Cave. A small excavation attempt was first made in 1957 by Prof. Dr. İ. Kılıç Kökten (Kartal, 1999).

d. Boynuzluin Cave

It is 30-31 km north-northwest of Antalya City centre; about 1 km northeast of Karain Cave and about 250 m northwest of Öküzini Cave. It is very close to the Kırkgöz water sources. It was discovered in 1990 by the speleologist P. Lacroix; a member of the Karain excavation team. The discovery of the cave; which is completely closed; was based on the discovery of two carob trees in front of the cave; hence the name Boynuzluin (Tay Projesi, 2023).

e. Öküzini Cave

Öküzini Cave is located within the borders of Yağca Neighbourhood of Döşemealtı. It is close to Karain Cave. It was first discovered and excavated by Prof. Dr. İ. Kılıç Kökten in the 1950s. The cave was named after an engraving of an ox found on the cave wall (Kartal, 1999). Besides these caves, there are other noteworthy sites (Suluin, Macarini, Deliktaş, Koyunini, Kireçini, Balcak-I and Balcak-II caves and rock shelters) related to the Late Upper Palaeolithic and Epi-palaeolithic periods (Kartal, 1999) (Figure 4).

Figure 4. a. Ox Engraving on the Cave Wall b. Grave (Department Archive, Kartal, 1999)

3.1.2. Ancient Cities

a. Termessos Ancient City: Termessos is located in the northwest of Antalya, within the boundaries of the Termessos National Park of Güllük Mountain, about 35 kilometres from the city centre. The city was built on a mountainous terrain starting at 908 metres above sea level and reaching 1254 meters. It is stated that the city dates back to the third millennium BC, that Arrianos mentioned it for the first time in his chapter on the Asian campaign of Alexander the Great and that Termessos gained its true urban identity in the Hellenistic Period. Today, the oldest structures in the city that can be dated with certainty are the stoas of Osbaras and Attalos, the great theatre and the Pan Temenos built in the Hellenistic Period, but Lanckoronski mentions the existence of graves and an inscription dating to the IV, III and II centuries BC. It is stated that the additional walls were fortified in even earlier periods and the oldest of them was influenced by the Hellenic Civilisation. Since there was no need to completely enclose the settlement area, which was naturally protected by its geographical location, walls were built only to the east of the hill on which it was located (Kürkçü, 2016) (Figure 5).

a

b

Figure 5. a. Amphitheatre of the ancient city of Termessos and b. Rock tombs in the ancient city of Termessos (Original Photo: Gül, 28/08/2021).

b. **Ariassos Ancient City:** The city of Ariassos is located 56 km northwest of Antalya province at an average altitude of 900 to 1050 meters. In 1988, S. Mitchell & M. Waelkens (1989, 66) dated the foundation of the city to this period, i.e. 189/188 BC, based on the Hellenistic city centre, where grave inscriptions, Bouleuterion and Prytaneon were found after the first survey in the city. Among the buildings constructed in the expanding city during the Roman Period are the monumental fountain (nymphaeum), gymnasium and baths, which were fed with water brought by an aquaeductus from a spring above the village of Akkoç, 3 km south of the city. According to Mitchell, two cisterns for storing the water for the bath complex, supplied by the aquaeductus, are located in the square in front of the nymphaeum. It was placed under the floor in the west (Kürkçü, 2015) (Figure 6).

Figure 6. Ariassos Ancient City: (Döşemealtı Municipality, 2016)

c. **Anydros - Eudokias Ancient City:** Eudokias is located 17 km northwest of Antalya city centre, on the plain (Düzlerçamı Plain) where Yukarı Karaman is located today, on the western edge of the Pamphylia Plain in Antiquity, on the Antalya- Korkuteli highway. In the 19th

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

century, L. A. O. de Corancez (1809, 1812), Ch. Texier (1834, 1836), T. A. B. Spratt and E. Forbes (1842), A. Schönborn (1842), E. Th. Daniell (1842), E. J. Davis (1872) and J. Seiff (1872) are known to have visited the city. According to modern travellers and researchers, the ancient settlement has two necropolises, one in the east (around Evdirhan) and the other in the south (between the southern road and the Kuruçay stream bed in the west). The dominant grave type in the necropolises is Termessos-type sarcophagi with shields. Another grave type is the monumental tombs. The large and small tumuli formed by piling travertine rubble stones, the two largest of which are in the eastern necropolis, first identified by Italian researchers Paribeni and Romanelli, are also one of the common grave types of the region. According to H. Rott; between 421-431 A.D. it was named "Eudokias" in honour of Aelia Eudoxia, the wife of Emperor Arcadius, and gained the status of a city (polis) within the territorium of Termessos. The city was counted within the united province of "Lycia and Pamphylia", which is known to have been founded in 74 AD. In 313, when Lycia and Pamphylia were separated from each other and turned into independent provinces, it remained within the borders of the province of "Pamphylia". The most distinctive feature of the ancient settlement in terms of urbanism is that it is an open settlement without a city wall around it and that it lacks an acropolis. This feature of the settlement is an important indication that it was not an independent settlement, but a rural-agricultural settlement located within the territory of a fortified main city where its inhabitants could take shelter when necessary (T.C. Antalya Valiliği. (2023).

3.1.3. Historical and Archaeological Structures

a. Bademağacı Mound: The mound was excavated in 1993 and is an archaeological site located 2,5 km northeast of Döşemealtı District, 5 km north of Çubukbeli Strait. The former name of the mound is Kızılkaya. It is located on a small plain with a length of about 8 km and a width of 6 km surrounded by mountains. The mound has a long diameter of 210 m in the north-south direction, a short diameter of 110 m in the east-west direction and the height of the highest point of the mound is 7 meters (Duru, 1996) (Figure 7).

Figure 7. Bademağacı Höyüğü (Kızılkaya) Excavations 1993 Study Report (Duru, 1996).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

b. Üstünağzı Ruin

It is located on the northern foot of Mercimek Mountain where the old village of Üstünağzı was situated. In the Üstünağzı settlement; which the ancients called "Melli Asarı", there are ruins spread over a wide area around the ruins of the building where large block stones were used; giving the impression that it was a temple or heroon (monumental tomb structure), and ancient graves concentrated on the lower hill to the north (Ercenk, 1992) (Figure 8).

Figure 8. Üstünağzı Ruin, (Original Photo: Öncü, 28/07/2023).

c. **Evdır Han Kervansarayı (Caravanserai):** Evdirhan was built by the 1st Izzeddin Keykavus Bin Keyhusrev in H. 607-616 / M. 1210-1219. It has a rectangular plan close to a square with a size of 67x55 square metres. All of the body walls are of cut stone and the upper cover is of rubble stone. The portal of the building in the group of han (inns) with four "eyvan" is especially remarkable. It is idle today. Restoration works are ongoing to revitalise Evdirhan (Türkiye Kültür Portalı, 2023) (Figure 9).

Figure 9. Evdır Han (Türkiye Kültür Portalı, 2023).

d. **Kırkgöz Han:** It is located 30 km from Antalya-Burdur motorway. It is within the borders of the Bıyıklı Neighbourhood of Döşemealtı District and in the Pınarbaşı location. The inn takes its name from Kırkgöz, the old name of the Döşemealtı district. The name Kırkgöz was given because there are many water sources in this region. Like Kırkgöz Han, the lake

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

where the spring waters accumulate also got its name from here. The building, which has a water source nearby, is located on a plain. Kırkgöz Han, which is today among agricultural lands, is on the Antalya - Isparta caravan route of the Anatolian Seljuk Period and is considered to be a range point continuing as Evdir, Kırkgöz, Susuz, İncir Han. The inscription of Kırkgöz Han is placed on the entrance door, in the centre of the arch keystone and measures 0.50 x 1.10 m. The inscription is enclosed in a rectangular frame and has six lines. According to the name mentioned in the building inscription; it was built in 633-644 AH (1236-1237 AD) by the Anatolian Seljuk Sultan Gıyaseddin Keyhüsrev II. (Yurdasever, 2011).

Figure 10. Kırkgöz Han, Han Entrance Gate and Han Interior (Original Photo: Öncü, 28/08/2021).

e. **Historical Ancient Döşeme Boğazı:** For Rome, road networks are considered one of the most important symbols of its sovereignty and one of the instruments of power. All Roman emperors attached great importance to the construction of better and shorter roads, road maintenance and inspection to be able to learn about what was happening in the lands under their sovereignty as soon as possible. It has been determined that the courier organisation (cursus publicus), which carried news from the provinces to the central administration, provided the opportunity to manage the whole empire from Rome (Figure 11).

According to Prof. Dr. Sencer Şahin, as shown in the road guide monument found in Patara in 1994, Emperor Claudius, immediately after the provincialisation of the region in 43 AD, had 67 routes connecting the cities of Lycia built through the first Governor Quintus Veranius and had their distances measured one by one. The 2000-year-old ancient Döşeme Road in the Döşeme Boğazı within the borders of Kovanlık Neighbourhood, which is in very good condition, is one of the oldest roads of strategic importance connecting the cities of Lycia, Pisidia and Pamphylia, especially the cities of South and South East (Çekirge, 2014). It is located at the northern foot of the Mercimek Mountain at the western end of the Döşeme Strait. A few kilometres east of Ariassos, located at the northwestern end of the Çubuk Strait, which the ancients called "Melli Asarı", is the Üstünağzı Ruin. It is the place where the Döşeme Boğazı road, which connects Antalya Port to Western and Central Western Anatolia, gets rid of the stream bed through which it passes and reaches the high plain, where it is divided into lines extending in different directions, that is, fork (Ercenk, 1992; Varsak Belediyesi, 2007).

From the remains and milestones found at certain points of the ancient road of Döşeme; it was determined that the roads were controlled by establishing military centres that controlled the

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

traffic on the roads. Due to the geographical characteristics of the region; very few trade and transport routes were established. It is stated that the smallest conflicts on these roads, which are very sensitive and constantly monitored, cause the road traffic to stop (Takmer & Önen, 2008).

It is understood from the inscriptions on the milestones that the ancient Roman road called "Via Sebaste", the earliest date of which cannot be determined exactly, was built by Augustus (Octavius), who was emperor for forty years, especially to combat Kilikyalı (Cilician) pirates. One of the 3 milestones recovered from Döşeme Boğazı shows that the road in question was built by Augustus through Cornutus Arruntius Aquila, the governor of Galatia Province, in 6 BC and was named Via Sebaste (Takmer & Önen, 2008; Varsak Belediyesi, 2007). It is stated that this road, known as "Via Sebaste", was built by Emperor Caesar Augustus, the son of God (Lulius Caesar) and that the construction was supervised by the Governor (legatus pro praetor) Cornutus Aquila. The 139 mil caput viae (starting point of the road) given on the milestone found in the Döşeme Boğazı indicates that Pisidia Antiokheia is located in Isparta / Yalvaç (Ercenk, 1992; Varsak Belediyesi, 2007).

The archaeologists who deciphered the milestones of the paved road have enlightened the history of the region. Starting from Pisidian Antioch (Yalvaç), Neapolis (Şarkikaraağaç), Hüyük, Iconium (Konya), Misthia (Beyşehir), Side, it is emphasised that it was built in 6 years BC and especially after circumnavigating the Beyşehir Lake, one branch extends to Syedra and the other to Antiocheia and Osione via Tarsos, that is, Syria and Mesopotamia (Çekirge, 2014).

e. Water Cisterns

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Cisterns are water storage structures that were reached as a result of the research on the method and form of storing rainwater due to the lack of spring water and low groundwater level, and their usage features were developed over time.

Due to the geographical location of the Döşemealtı Region, the ancient cities in the region the ancient "Döşeme Boğazı (Strait)" road and the water cisterns built by the Yörükler (Yoruks) on their migration routes are important cultural values. The scarcity of water resources in high regions, which receive abundant rainfall due to their characteristics and thus should be in good condition in terms of water availability, has enabled the development of rational solutions for finding and storing water, thus ensuring the continuation of life without interruption (Ercenk, 2012).

It was observed that the well clusters and cisterns seen in the Döşemealtı region were concentrated on or in the close vicinity of thousands of years old road lines that provide access to production and trade areas; to solve the problem of finding and storing the water required during transportation (Ercenk, 2012). The architectural diversity and number of cisterns seen in the Döşemealtı plain are remarkable. Although it is correct to attribute the presence of a large number of cisterns to animal breeding in a region where thirst is almost registered, it is insufficient. On the other hand, the fact that cisterns and wells of various models and densities are not encountered except for a few examples in the distant and close neighbourhoods, which are engaged in nomadic animal husbandry and have cultural ties with the region, shows that the cisterns on the Döşemealtı plain are unique. The "water storage structures", which are unique to the region dating back to the periods before the nomadic life, have been used until today with some changes in their form and volume and restoration when necessary (Ercenk, 2012). (Figure 12, 13,14,15).

(Vuruşkan & Ortaçşme, 2009; ÇSİB, 2018).

Natural Protected Areas; Düzlerçamı Forest, Pigeon Cliff, Termessoss Ancient City and National Park, Kirkgoz Water Springs, Harunini Cave, Kizilin Cave, Oxenini Cave, Koyunini Cave, Mustanini Cave, Macarini Cave, Carkini Cave, Suluin Cave, Church Duden Cave Tabak 1 and Tabak 2 Caves etc. (Vuruşkan & Ortaçşme, 2009; ÇSİB, 2018).

3.1.5. Traditional Architecture: There are many examples of traditional civil architecture in the Döşemealtı Region, which are included in Intangible Cultural Values, but most of them are abandoned or idle. There are no registered traditional civil architecture dwellings (Figures 16, 17, 18, 19).

3.1.6. Local Handicrafts

Based on Cultural Heritage, it is important to preserve and transfer the thousands of years of local handicrafts, which are one of the living cultures that create and develop this richness, and the accumulations that will inspire the future. The history of Traditional Turkish Handicrafts dates back to ancient times, in Central Asia. The characteristics of nomadic life, which is a way of life in handicraft products, are also understood from historical remains. Embroidery and motifs were applied to tents, carpets, rugs, saddle sets, dresses, etc. in that period. Turks living in Anatolia have left historical traces by reflecting this rich and diverse art and civilisation cultures. (Öncü, 2013). The Turkish tribes who settled in the Döşemealtı region continued to develop and develop the nomadic culture embroidery and arts of Central Asia here.

In Döşemealtında, while many handicrafts were made, most of these arts have been lost, and weaving, which continues to decline today; Halıcılık (Carpet weaving), heybe (saddlebag)

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

weaving, çarpana (Multiplier), yün çorap örme (Wool Sock knitting), hasır örme (Wicker Knitting), etc. It still comes to life in the hands of the last representatives of the professions. The lack of apprentices who will continue these art branches for economic reasons accelerates the disappearance of these professions.

Figure 20. Traditional Weaving Samples Detected in Döşemealtı Neighbourhoods (Original Photo: Öncü, 2022).

September 14-15, 2023, Naples, Italy

Figure 22. Akkoç Neighbourhood Multiplier Weaving and Çığlık Neighbourhood Wool Sock Knitting (Original Photo Fadime Öncü,2022)

3.1.7. Döşemealtı Carpets

Döşemealtı Carpets take its name from the region where it is located. According to the information obtained from the local people, the first Döşemealtı Carpet was started to be woven by Karakoyunlu Yörükleri (Yoruks) who settled in Kovanlık Village and New Ottoman Yörükleri (Yoruks) who settled in Aşağıoba village and spread to other villages of Döşemealtı.

In Döşemealtı carpets, 7 different colours are used: red, yellow, green, blue, dark red, black and white. The weft and warp of the carpets are made of wool yarn. Root Dye Plants: Root Dye, Sumac Plant, Sey, Ezentere, Lemon Salt, Sakızlık, Ash Water to be obtained from the ashes of any Oak and Acorn, Lemon Peel, Indigo, Root of Dried Labada Plant, Walnut Shell, Cattail, Acorn, Ironoxide (Mazıbaş, 2014).

Classification of Döşemealtı Carpets according to their models: 1– Halelli, 2- Dallı (Branched) (Tree of Life), 3– Toplu (Bulk), 4- Toplu terazili (Bulk Scale), 5– Mihraplı, 6– Akrepli (Scorpion), 7- Koca sulu (large watery) (Mazıbaş, 2014).

Classification According to Edge Motifs: 1- Tutmaç (Handle): Beştaş (five stones), Yıldızlı top (a Starry Ball), Bıçak ucu (Knife Tip), and Tutmaç. 2- Kocası Yantrı (Fold): Koç Boynuzu (Ram's Horn), Beş Parmak (Five Fingers), Kara Saban Demiri (Black Plough Iron), El Hayası (Hand Haya) motifs. 3- Develi Su: Deve ve çalı (camel and bush motifs). 4- Kenar Suyu (Edge Water): Keme dişi (Keme tooth) and Öküz sidiği (Ox urine) motifs. 5- Albay Suyu: (Albay Water): Elmalı Suyu (Elmalı Water) and Kazak Suyu (Kazak Water) (named after the Kazak Carpet brought from Kazakhstan by a retired colonel) motifs (Mazıbaş, 2014).

Classification according to size: 1- 2 m x 3 m size Floor Carpet, 2 - 1.26m x 1.83m Large Carpet 3 - 0.80m x 1.25m Namazlık (Prayer Rack) (Çeyrek=Quarter), 4 - 0.75m x 3m Yolluk (Runner), 5- 0.40m x 0.80m Divan Yastığı (Divan Pillow) (Topan). The number of knots of the Döşemealtı Carpet is counted from the back of the carpet per cm² or dm² (Mazıbaş, 2014).

Figure 23. Traditional carpet weaving examples detected in Döşemealtı Neighbourhoods (Original Photo: Öncü, 2022).

3.1.8. Döşemealtı carpet fields:

Carpet fields were first established in Killik Neighbourhood of the Döşemealtı District of Antalya Province in Türkiye and are still being continued today with 40-50 thousand pieces of weaving (Ekin, 2021). In the rented fields they use, they start on 22 June every year and are kept under the sun on 20 September. The weavings that come in winter are washed and put in warehouses to prepare them for the next season. It was stated that trials were made in certain parts of Türkiye, but no successful results were obtained and the reason for the success only in this region in Türkiye is the dew fall. Because when it is laid in the sun in a place where dew does not fall, it is stated that the sun burns the weavings, that is, blackens them.

Especially hand-woven carpets are laid on barren and slightly stony soil to be processed in the carpet field. The stones in the soil act as insulation and ensure that the soil does not lose heat. Thus, the soil causes the colour of the carpet to fade, that is, to pastelise. The sun does not affect the carpets and rugs woven with root dye. The weavings made with root dye are sunbathed against pests, moth-eaten or old places are repaired and offered for sale especially in Istanbul (Oral interview with Hasan Topkara, 2021) (Figure, 24, 25).

Figure 25. Carpet field located in the Döşemealtı Karaveliler Neighbourhood (Original Photo: Öncü, 2021).

3.1.9. Traditional clothing culture

The clothing of society carries value judgements, aesthetic views, artistic and many cultural elements. The constructive laws of nature, which are included in the Cultural Heritage, combined with human talent, and the clothes shaped according to their beliefs, tastes and emotions, with their apparent values, have created differences according to the way of view of the society in which they find themselves.

In this period when global culture makes itself felt in every field, Döşemealtı clothing culture with its traditional and original structure, has been going on since ancient times and has started to disappear today; It has a structure that will bring a lot of information and visual data about the old cultural structure of this region to our cultural history. The local clothes belonging to the Döşemealtı region are still common today except for a few neighbourhoods and are worn by women and girls when the henna night is held. It was observed that men's clothes have the same characteristics as the Antalya centre.

3. CONCLUSION and RECOMMENDATIONS

In this study, Döşemealtı District has been analysed in terms of cultural heritage and sustainability. As a result of the examination, it has been observed that there are very important values in terms of these issues. However, when the importance given to traditional cultural values within the scope of cultural sustainability in Döşemealtı is analysed, it is seen that ecology and sustainable environment issues are not given the necessary importance.

Although Döşemealtı District has very important values such as cultural heritage and sustainability, it has been determined that the relevant administrators do not pay due attention to cultural memory for the transfer to future generations.

The increase in migration from rural areas due to economic, social and political factors in the Döşemealtı region, the change in traditional lifestyle, and the lack of importance and indifference by managers and decision-makers led to the gradual loss of Cultural Heritage Values and functions.

Despite all these negativities, it has been observed that some cultural values continue in tangible and intangible cultural heritage items (Handicrafts, traditional food culture, traditional clothes, traditional life, etc.), which are among the sub-headings of cultural heritage and are not directly related to the subject of cultural heritage.

As a result of the content analyses, the following suggestions can be made to protect the cultural heritage in Döşemealtı region and to ensure its sustainability;

- The Ministry of Culture and Tourism, Municipality, Universities, ICOMOS (International Council on Monuments and Sites) which is an international and non-governmental organisation, NGOs and other stakeholders should act together to create a holistic strategic action plan for Döşemealtı Region.
- A holistic natural and cultural inventory of the Döşemealtı region should be prepared, digitised and updated in a GIS environment.
- Scientific research and projects should be produced in cooperation with relevant stakeholders.
- Local Authorities should be provided with more effective and competent opportunities for the protection and sustainability of cultural heritage.
- It should be obligatory to establish a protection, implementation and supervision bureau "KUDEB" within the Municipality by permitting Döşemealtı Municipality the Ministry to carry out the procedures and applications related to immovable cultural and natural assets that need to be protected and to carry out their inspections. This will contribute to the promotion of Döşemealtı District in terms of destination tourism. The Ministry of Culture and Tourism should request quarterly reports to follow up on the work carried out by the relevant institutions.
- The aim of conservation with a participatory approach in sustainable management is not to isolate the value from the society, but to bring the value to the society and to ensure that it takes place in cultural and social life and that the Cultural Heritage value contributes to economic and social development.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

- Cultural heritage awareness and consciousness-raising activities should be increased among local people.
- The fact that the traces of Döşemealtı Ancient Bosphorus are still partially preserved is of great importance for the protection and survival of this road as a cultural heritage value.
- The artefacts that constitute cultural heritage or cultural heritage, which have been preserved from the past to the present and created by previous generations and believed to have universal values, should be brought back to the society without isolating them from the society within the participatory approach in sustainable management, and it should be ensured that cultural heritage values contribute to economic and social development.

ABSTRACT

Furniture is an element that meets the basic needs of users and offers comfort and aesthetics to the user. Furniture design is shaped under the influence of various factors from the first stage. When designing furniture, there is a long process from the emergence of the first idea to the use of the furniture. With the furniture design courses given in interior architecture departments, students experience the furniture design process in the studio. For this purpose, the concept of lightweight furniture was discussed within the scope of Furniture Design II course conducted with third year students of Akdeniz University, Faculty of Architecture, Department of Interior Architecture and 24 of the resulting products were included in the study. In the study, it was expected that the furniture suitable for the definition of lightweight furniture should be easily portable and suitable for sitting comfortably. The study contributes to students' learning by doing and the process was completed in 3 stages: designing, planning and production. The design and planning phase consists of concept and form determination, while the production phase consists of material selection and obtaining the final product. The furniture designed in this context were produced in different forms according to their concepts, using lightweight materials such as aluminum, beech wood, ayous wood in one-to-one dimensions. Thus, students both interpreted the form by using the material and experienced the production process of the furniture they designed during their education process.

Keywords: Furniture, Concept, Material, Lightweight Furniture, Design Education.

1. INTRODUCTION

If we examine the etymology of the word furniture, the Latin word "mobilis" (moving) was adapted to the late Latin word "mobiliaria" (movable). The word "mobiliara" is adapted to the French word "mobilier" (a movable object) and used as the word "mobilya" in our language (Karabıyık, 2009). Although the word furniture means a mobile object that can be moved, it is generally accepted as an equipment element (Tütüncü, 2011). Furniture can be defined as safe

and comfortable designed items that address people's basic physical needs (such as sitting, sleeping, working and storage) as well as social and cultural dimensions (Çetin, 2022). Furniture is a functional item that appeals to people's tastes in a place where they spend time during the day or can be used to equip a place for different purposes according to the conditions of different periods. According to this definition, it is understood that furniture is a product in which art and technique, which have functional and aesthetic values, are combined (Karabiyik, 2009). It is also important that furniture should be ergonomic along with its functional and aesthetic elements. All of these elements should be considered together in furniture design.

Interior architecture is a profession that responds to the functional needs as well as the aesthetic expectations of the user and uses technical information to create the most suitable environment (Berdi Gökhan & Atasoy, 2005). Furniture is one of the most important elements of interior design. Interior architects should have a sufficient level of knowledge about furniture. This knowledge includes material properties and production knowledge (Altın, 2016). Experiencing the production process also contributes to the problems that will arise in the process and the solutions that will be developed to overcome these problems.

The aim of interior architecture education is not only to transfer knowledge to students. Among the primary goals of design education is that students should try to adopt the understanding of how they can improve themselves in their education and benefit from the education process at the highest level (Çetinkaya, 2014). Interior architecture education consists of a curriculum in which practice courses are predominant. One of the practical courses in interior architecture education is the furniture design course. As suggested by Chikering and Gamson (1987), the educational model where students sit in the classroom and listen to their teachers' lectures is not suitable and effective for architecture. However, it is pointed out that active learning will yield positive results when students are the main participants in the learning process (Keyser, 2000). In this framework, in 1915, John Dewey and Evelyn Dewey proposed "learning by doing", an educational model that can increase students' interest and attention, and this model has an important place in architectural education. The student who endeavors to learn by doing and tries to create a product benefits from the process of "designing, making and producing" that takes place simultaneously with the goals of his/her education. Students generate solutions to the challenges encountered in the design and construction processes. The learning-by-doing approach plays an active role in the search for materials and the planning of the building process, acting as a bridge of experiential knowledge between theory and practice (Mun & Arslan Selçuk, 2018). Learning by doing brings together two different types of knowledge that can and cannot be transferred to students in the studio. It also contributes to students' creativity as they take part in an interactive learning style through the learning-by-doing method.

Students' personal experiences with furniture production are important to understand that the conceptual approach to design, as well as the materials and production techniques during the production phase, can change the design unexpectedly. In the design education approach, production proceeds independently of design and conceptual infrastructure comes to the fore. Many issues related to furniture design and production such as materials, production methods and details cannot be evaluated in the education process. To find a solution to this situation, an educational approach that combines furniture design with production is needed (Altın, 2016). It is necessary to use methods and techniques that will positively affect learning in design education, where practical courses are weighted.

2. MATERIALS and METHOD

2.1. Materials

The material of the study was selected by the students among the works designed within the scope of the Furniture Design II course in the Fall Semester of the 2022-2023 academic year. At Akdeniz University, Faculty of Architecture, Department of Interior Architecture, 105 students took İÇT 343 Furniture Design II course in the fall semester of 2022-2023. Among these students, 63 students were able to produce a final product. 24 students' final products were selected because they fit the definition of lightweight furniture (Table 1).

2.2. Method

Within the scope of the Furniture Design II course conducted in the 2022-2023 Fall semester at Akdeniz University Faculty of Architecture, Department of Interior Architecture; students were asked to create a furniture design that would define "Lightweight Furniture". In the formation of furniture design, problem, information gathering, alternatives, evaluation and production stages were followed (Acar & Bekar, 2017; Akyol, 2006).

The design process followed in the Furniture Design II course is as follows:

- *Problem:* Designing a seating element that is suitable for the concept of lightweight furniture, easy to move and comfortable to sit on
- *Information Gathering:* Creating a concept and scenario. What kind of shape will the furniture be in? What kind of ergonomic solution will they need to produce suitable for this form? How will it make the furniture feel lightweight? seeking solutions to questions such as

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

- *Alternative:* Creating more than one design with sketches and 3-dimensional narratives. (While creating alternatives, the necessary information was taken from the feedback, information collection and concept stages.)
- *Evaluation:* Preparation of 2D drawings, graphic descriptions, 3D descriptions, material details, and joint details of the final product
- *Production:* Production with real material in 1/1 scale

3. FINDINGS and DISCUSSION

The lightweight furniture was evaluated in 3 stages in accordance with the learning-by-doing method; interpretation of the design through a concept (concept development), material selection, and evaluation of the final product produced in one-to-one scale.

3.1. Concept Development

In the concept creation phase, students are expected to put forward their design strategies according to the topic of "lightweight furniture". While the concept was being developed, it was requested to design a seating element that is suitable for the concept of lightweight furniture, easy to move and comfortable to sit. At this stage, students created their scenarios by collecting information appropriate to the problem (Table 2). During the concept development phase, it was discussed with the students whether the concept of lightness could be defined as weight only or whether the furniture would be suitable for the definition of lightweight furniture by using spaces in the furniture.

Student: Mehveş Bengüsü Helvacı

Şövaleden esinlenen hafif mobilya tasarlanabilir ve sergi kullanılabilecek şekilde tasarlanmıştır.

Student: Mert Can Ercan

At the concept stage, it was expected that the furniture to be designed would be able to meet the needs. In this process, it is important what else the user may need and how value can be added to the product. After the definitions of the furniture were made, visual studies and sketches began to be drawn. The most appropriate one among alternative concepts is selected and detailed. This process allows the designer to proceed in a more controlled manner and to achieve a more concrete and understandable result.

3.2. Material Selection

Within the scope of the study, students' choice of materials suitable for the concept of lightweight furniture constitutes an important stage of the study. At this stage, it has been revealed which materials will benefit due to which properties.

Students decided on the forms of their furniture according to the limitations of the materials they researched (Figure 1). In addition, students experimented with joint details according to

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

the properties of the materials. The choice of material in the study enabled the students to discover the material and caused the designs to progress as the materials allowed.

Figure 1. Furniture designs at the material selection stage

As a result of their research, the students suggested the following materials for use in furniture design (Figure 2):

- For its structure; aluminum, chrome, beech wood, ayous wood.
- For its upholstery; tarpaulin, sunbed fabric, artificial leather, upholstery linen, wicker rope, polyurethane waterproof fabric, knitted rope, upholstery sponge, transparent pvc.
- For its joints; 3d printer, allen screw, bolt, nut, lift lid scissor mechanism, hinge, special fasteners.

Figure 2. Some of the materials that students use

The reason why the majority of students choose aluminum for the structure of furniture is that it is light in weight. They wanted the furniture to reflect the lightness visually by using various types of rope such as wicker rope, knitted rope for furniture upholstery. In addition, they have used folding, disassemble-install mechanisms in their furniture for easy portability of lightweight furniture.

3.3. Final Product Produced in One-to-one Scale

Students started the process of creating products on a 1/1 scale with the data obtained from the previous stages. As a result of the concept, sketch drawings, 2D drawings, 3D modeling, model trials and material selection they started to produce furniture in one-to-one scale (Figure 3). First, they provided the supply of the materials they selected. During the production phase, they cooperated with masters in the industry to bring their designs to the appropriate form according to the limitations of the selected materials. They had the opportunity to learn the joint details of the furniture by seeing them on a one-to-one scale.

4. CONCLUSION and RECOMMENDATIONS

This study deals with a process that aims to provide furniture design and production experience, and it is aimed to increase student's awareness in this direction and guide future studies. In this context, the relationship between the design process and the learning-by-doing method in terms of the furniture design course and its stages are defined (Figure 4).

Firstly, it defined a more controlled area in the act of designing by giving students a concept. Students attributed multidimensional meanings to the concept of lightweight furniture. Among these meanings, the concept of weight and the definition of space have developed. In addition, portable and removable features and lightweight features are supported in the designs.

In this study, material selection played an important role in the design process, which started with collecting information and sketches in furniture design. Students were able to explore the materials needed to design lightweight furniture. It caused the designs to progress as the selected materials allowed. Students made designs with materials on a one-to-one scale. The furniture design course does not only focus on model applications but also benefits their professional development with one-to-one practice.

Students had an active and participatory experience in the planning, production and assembly stages of furniture designed with the learning-by-doing method. It is thought that the active participation of students in the application processes will contribute to their faster adaptation to business life after the university environment. However, the applied education model and this new learning experience can also be included in different courses in the interior architecture education process.

Thanks and Information Note

We would like to thank the authors who are course instructors, Interior Architect Yalın Acun, Interior Architect Tahir Büyükkaya, Architect Reyhan Ay, and our students who made this experience possible, for their contributions to the Furniture Design II course at Akdeniz University, Faculty of Architecture, Department of Interior Architecture.

ABSTRACT

The concept of authenticity is a term that is prominent in restaurants as well as other fields that include cultural accumulation. Interior design is seen as one of the main factors in ethnic restaurants where authenticity depends on many factors. Although the purpose of these restaurants, which have themes from many different cultures such as Italian, East Asia, Ottoman and Korean, is to create a sense of authentic place for the customer by applying authentic places, the result can be commodification. The expectation of tourists to experience different experiences has developed with the changes in the understanding of tourism; hotels, one of the important structures of the tourism sector, have also changed their understanding of content and have started to include restaurants that can be defined as authentic as a service. In this context, the hotels in Antalya, which were built or renovated in the last 3 years, and which have a restaurant designed as an "Italian Restaurant", selected among the 5-star hotels in Antalya, have been examined based on the spatial components and elements created by İlkay Özdemir (1994). As a result, the concepts of authenticity and commodification were discussed over the selected hotels, and the components and elements of the restaurant were evaluated in terms of restaurant interiors.

Keywords: Commodification, Authentic, Italian Restaurant, Ethnic, Color, Cultural Heritage, Furniture.

1. INTRODUCTION

Commodification can be defined as the alteration and trivialization of cultural values and human relationships (Cohen, 1988). Although there have been studies related to the commodification of a place with a specific cultural heritage due to tourism's integration into everyday life (Greenwood, 1977), this situation is not sufficient to answer whether the design resulting from the authentic representation of a culture in a new location is authentic or commodified. Due to increased cultural awareness, modern society has sought authenticity in consumer products and services (Gilmore & Pine, 2007). The concept of authenticity is prominent not only in fields with cultural accumulation but also in restaurants. Literature shows that the authenticity of a restaurant affects customer satisfaction, and customers who frequently visit ethnic restaurants seek ethnic cultural experiences (Bell et al., 1994). Wood and Munoz, on the other hand, describe ethnic restaurants as more than just food service establishments;

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

they define them as cultural "ambassadors" that introduce foreign cuisines and the culture associated with them (Wood & Munoz, 2007). There are several factors that determine the authenticity of ethnic restaurants. Research by R. Thomas George in 2001 indicates that interior design and decoration are determining factors in the authenticity of a place (George, 2001). Ethnic restaurants have themes from various cultures such as Italian, East Asian, Ottoman, and Korean. According to one study, Chinese-themed ethnic restaurants in America are staffed by family members, have ethnic Chinese decorations and paintings, offer menus in both Chinese and English and provide Chinese cultural elements such as chopsticks and tea sets (Liu & Jang, 2009). Another study on Korean restaurants suggests that the authenticity of Korean restaurants is related to the interior and exterior design, music, and decoration, which incorporate Korean culture with furniture, colors, and music (Jang et al., 2011). While the goal in such restaurants is to create an authentic atmosphere for customers, the result can sometimes be commodification.

Changes in tourism expectations, driven by changes in tourism understanding, have led to hotels, one of the key structures in the tourism sector, altering their content and incorporating restaurants that can be defined as authentic within their premises. As an example of such restaurants, the Italian/Mediterranean-themed à la carte restaurants in 5-star hotels located in the Manavgat district of Antalya, which has the highest number of 5-star hotels in Turkey, can be cited.

Italy has a significant cultural and artistic history, with renowned artists and works in literature, especially during the Renaissance period, such as Leonardo Da Vinci, Raphael, Michelangelo, and Giotto (Vasari, 2013). According to the literature, both the Renaissance and the period after World War II played a critical role in the formation of Italian furniture design (Aksoy, 1992; Dal Falco, 2019; Dellapiana, 2018; Barisione, 2020). Until 1946, Italian design was influenced by both cultural and structural aspects of Rationalist architecture. During this period, certain raw materials, especially wood from the boxwood plant and linoleum, were frequently used due to limited resources caused by the war. According to Aksoy, in the years immediately after the war, Italians rapidly adapted to new materials and continuously used them in new furniture designs. In the 1960s, with the economic acceleration, new methods were developed, and plastic material became prominent. Although the 1970s were challenging, Italian design gained international recognition during this period. In the 1980s, the imaginative, unexpected, and alternative designs created by the Italian furniture industry opened new horizons in the international design world. Aksoy mentions new materials and usage methods such as wood, lamination, plywood, metal, and plastic during this period.

This article aims to examine whether the spatial designs of authentic restaurants within the 5-star hotels, whose numbers are increasing day by day, possess authentic or commodified qualities based on ethnic values as part of the spatial components and elements created by Özdemir (1994). This article aims to examine restaurants designed as Italian Restaurants, based on the spatial components and elements created by Özdemir (1994), and to evaluate the findings in terms of authenticity and commodification concepts.

2. MATERIALS and METHODS

In the scope of this study, 5-star hotels in Antalya that have been constructed or renovated within the last 3 years and feature an "Italian Restaurant" have been selected. The selection of Italian restaurants within 5-star hotels in Antalya was based on the criteria that Antalya has the

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

highest number of 5-star hotels in Turkey and is the city that hosts the most foreign tourists in Turkey. When choosing the 5-star hotels, attention was given to the fact that they were all designed by the same project firm within the last 3 years, located in the same region, and catering to similar customer profiles. The selected hotels are shown in Table 1.

Table 1. Hotels Selected As Examples

Number	Name Of The Hotel
1	Mylome Resort Hotel
2	Seaden Quality Hotel
3	Diamond Deluxe Hotel
4	Bella Resort Hotel
5	Narcia Hotel

Figure 1. Mylome Resort Hotel

All of the Italian/Mediterranean restaurants in these hotels have been designed by the firm named Tuba Soner Design Office. The relevant three-dimensional visuals of the restaurants are provided below (Figure 1-4).

Figure 4. Narcia Hotel

Özdemir (1994) defines spatial components as elements that emerge during the creation of a structural space. Özdemir (1994) emphasizes that these components and elements play a significant role in the overall effect of space and discusses their divergent functions. These components are often fixed and typically assume determining and limiting roles in shaping the interior space. Spatial elements, on the other hand, are defined as concepts that take their place in the space after the formation of the structural space and are movable elements that vary according to the user's needs and desires.

In summary, Özdemir (1994) mentions that compositions are dependent on spatial components and that these components can have limiting qualities. For example, a "carpet" can serve as a solid boundary within a space, while furnishings and accessories are arranged within the boundaries of the carpet.

The spatial components identified by Özdemir (1994) include flooring, walls, columns, beams, roofs, stairs, doors, and windows, while spatial elements include furnishings, items, and accessories such as chairs, tables, and other items. These spatial components and elements will be examined with a focus on cultural history, color, and furniture as elements that indicate the authenticity of a space. The findings will be analyzed under the main headings of components and elements, with each of these categories having its subheadings.

3. FINDINGS and DISCUSSION

The study findings consist of two main categories, as identified by Özdemir (1994), within the Italian Restaurants in the hotels. The first main category is "spatial components," which includes flooring, walls, columns, beams, roofs, stairs, doors, and windows. The second main category is "spatial elements," which encompasses movable furniture, items, and accessories.

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

3.1. Spatial Components

It defines spatial components as elements that emerge during the creation of the structural space. These components are fixed and mostly assume determinative and limiting roles within the interior space.

3.1.1. Flooring as a Spatial Component

In the Italian restaurant of the Mylome Resort Hotel, two different ceramics and a single type of marble are observed to be used for the flooring. Throughout the space, anthracite-colored textured ceramics dominate, while in some sections, blue and white ceramics, which can be ethnically defined, are used. These two ceramics are integrated with black marble used as a border. In the Italian restaurant of the Seaden Quality Hotel, the flooring consists of three different marbles in black, gray, and white with CNC-cut patterns. At the Diamond Deluxe Hotel's Italian restaurant, the flooring is observed to be made of black and white CNC-cut marbles, creating two different patterns, with black marble borders connecting them. At the Bella Resort Hotel, six different ceramics and two different marbles are used. Throughout the space, textured anthracite ceramics are used, while in some sections, earth-colored ceramics with Hungarian patterns are laid, and in other sections, black and white marbles with CNC-cut patterns are used to create designs. In the Italian restaurant of the Narcia Hotel, one type of ceramic and two different marbles are observed to be used. White marble is used throughout the space, with black marble serving as a border, and in some areas, textured anthracite-colored ceramics are used (Figure 5).

Figure 5. Floorings From A'la Cartes

3.1.2. Wall as a Spatial Component

In the Italian restaurant of the Mylome Resort Hotel, the walls feature two different but similarly textured concrete-look plaster in yellow and green colors. Gold-colored metal borders are observed at the junction point of these two plasters. One of the walls has blue-colored glass with black metal frames on the front part of the plasters, and the upper part consists of metal pipes, forming a wall covering that extends to the ceiling. In the Italian restaurant of the Seaden Quality Hotel, the walls are adorned with wood veneer, wallpaper, and distressed-looking wall panels. The wood veneer used has an oak-like appearance with semi-circular cuttings. The

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

wallpaper is gray and has a linen texture. The distressed wall panel is a decorative panel based on styrofoam and features patterns reminiscent of the metal panels in front of stained-glass windows in Italian churches.

At the Diamond Deluxe Hotel's Italian restaurant, the walls display bricks, lacquered paneling, wood veneer, and marble with metal frames. The decorative bricks are white, and some sections feature silhouettes of Leonardo Da Vinci's self-portrait, a quote attributed to him, and the silhouette of the female figure from his artwork, the Mona Lisa. Gray lacquered panels have lacquered frames, and some parts of the walls resemble columns from the Ancient Greek era, created from lacquered paneling. Walnut veneer wainscoting strips are present at some points where the white brick and lacquered paneling meet. In niches within the gray lacquered panels, there are gold-colored metal-framed panels with white marble-like patterns, and within the white marble, there is an intricate gold border in a baklava pattern.

In the Italian restaurant of the Bella Resort Hotel, the walls feature decorative plaster, distressed wall panels, metal-framed glass panels, and artificial plants. Four different textures and colors of decorative plaster are used, with anthracite-colored concrete-textured smooth plaster being predominant. Some areas feature white textured aged-looking plaster, abstract-looking plaster with predominant white and green tones, and damaged texture plaster in green, gray, red, and blue. The distressed wall panel consists of anthracite and gold-colored tile-like panels. The metal-framed glass panel is made up of interconnected glass tiles with a baklava pattern in gold, linked by gold tube metals.

In the Italian restaurant of the Narcia Hotel, the walls are adorned with stone cladding, wall paint, and wood veneer panels. White stones are used for the stone cladding, with some areas featuring oak veneer panels with wood knots. The rest of the space has been dyed plain wall paint (Figure 6).

Figure 6. Walls From A'la Cartes

3.1.3. Column as a Spatial Component

In the Italian restaurant of the Mylome Resort Hotel, columns feature polyurethane cladding reminiscent of the Ancient Greek period, and the metal border that combines two different textured plaster colors on the walls also continues onto the column cladding. At the Seaden

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Quality Hotel's Italian restaurant, all columns are covered with half-moon cut oak veneer, and the baseboard sections are covered in black lacquer. In the Italian restaurant of the Diamond Deluxe Hotel, the columns continue the gray lacquered paneling with lacquered frames that is also used as wall cladding in some parts, resembling columns from the Ancient Greek era. In the Italian restaurant of the Bella Resort Hotel, the columns continue various decorative plasters used on the walls. In the Italian restaurant of the Narcia Hotel, the columns are adorned with oak veneer panels with wood knots, similar to the wall cladding used on the walls (Figure 7).

Figure 7. Columns From A'la Cartes

3.1.4. Column as a Spatial Component

In the Italian restaurant of the Mylome Resort Hotel, the beams continue the textured yellow plaster used on the walls. In the Italian restaurant of the Seaden Quality Hotel, beams are not visible, so nothing can be observed. In the Italian restaurant of the Diamond Deluxe Hotel, beams are not visible, so nothing can be observed. In the Italian restaurant of the Bella Resort Hotel, black wall paint is used on the beams. In the Italian restaurant of the Narcia Hotel, the beams continue horizontally as an extension of the oak veneer panels with wood knots, which also continue from the columns (Figure 8).

Figure 8. Beams From A'la Cartes

3.1.5. Ceiling as a Spatial Component

In the Italian restaurant of the Mylome Resort Hotel, the ceiling features white concrete-textured plaster, and various types of lighting fixtures such as chandeliers, pendants, and spotlights are used. In the Italian restaurant of the Seaden Quality Hotel, the ceiling has wooden slats with intermittent white lacquered sections containing recessed spotlights in one part, while another part consists of anthracite-colored flat wooden lacquer panels with joints. In the Italian restaurant of the Diamond Deluxe Hotel, a portion of the ceiling with lower height is painted in white and anthracite, while the remaining section is covered with clear mirrors arranged in beveled tile-like pattern. At the junction where the high part of the ceiling meets the white ceiling paint, walnut veneer is used. In areas where the ceiling height is high, walnut veneer wood panels are observed. In the Italian restaurant of the Bella Resort Hotel, red brick cladding is used in the area where the ceiling is lowered, and the rest of the ceiling is painted in black. In the Italian restaurant of the Narcia Hotel, the entire ceiling is painted in white (Figure 9 and Figure 10).

Figure 9. Ceilings From A'la Cartes

Figure 10. Ceilings From A'la Cartes

3.1.6. Door as a Spatial Component

In the Italian restaurant of the Mylome Resort Hotel, two types of doors are observed. The main entrance consists of a double-wing black aluminum-framed door, while the kitchen door is a white lacquered wooden door with a wooden frame and a gray metal kickplate at the bottom. In the Italian restaurant of the Seaden Quality Hotel, two types of doors are used. The main entrance features a double-wing black aluminum-framed glass door, while the kitchen door is made of oak veneer wood material, which is also used in the wall and column coverings. The door has oak veneer both on the frame and the wing sections, and it has a gray metal kickplate at the bottom. In the Italian restaurant of the Diamond Deluxe Hotel, two types of doors are observed. The main entrance consists of a double-wing black aluminum-framed glass door, while the kitchen door is made of gray lacquered material, which is also used in the wall coverings. The door has gray lacquer on both the frame and the wing sections, and it has a black metal kickplate at the bottom. In the Italian restaurant of the Bella Resort Hotel, a black aluminum-framed glass door is used, with horizontal black aluminum profiles. In the Italian restaurant of the Narcia Hotel, a double-wing gray aluminum-framed glass door is used, with a partition in the upper part made of vertical aluminum profiles and aluminum tiles (Figure 11).

Figure 11. Doors From A'la Cartes

3.1.7. Window as a Spatial Component

At Mylome Resort Hotel's Italian restaurant, black aluminum-framed glass windows with horizontal and vertical aluminum framing creating partitions are observed. In the Italian restaurant of Seaden Quality Hotel, there are arched black aluminum-framed glass windows with wooden sunshades in the arched section. In the three-dimensional works of the Italian restaurant of Diamond Deluxe Hotel, there is nothing observed related to windows. In the Italian restaurant of Bella Resort Hotel, three types of black aluminum-framed glass windows are observed. The first one is a glass window with horizontal aluminum profiles, similar to the door. The other two windows are in lattice patterns with aluminum framing, connected from end to end with diagonal aluminum profiles. In the Italian restaurant of Narcia Hotel, similar to the door, there are double-winged gray aluminum-framed glass windows with aluminum profiles dividing them, and aluminum-framed glass windows with cross-profiles in a lattice pattern (Figure 12).

Figure 12. Windows From A'la Cartes

3.2. Spatial Elements

Spatial elements are defined as concepts that take their place in the space after the formation of the structural space.

3.2.1. Movable Furniture as a Spatial Element

Mylome Resort Hotel's Italian restaurant features 2 types of chairs, 1 type of bench, 1 type of sideboard, and 3 types of tables. The first chair has anthracite-colored lacquered legs, an exterior covered in anthracite textured leather fabric, and an interior covered in cinnamon-colored leather fabric. The second chair has a hexagonal patterned fabric in blue and white for the backrest, while the seat is covered in white and anthracite fabrics, and it has shiny metal-looking gray legs. The bench has seating and backrest parts made of the same leather fabric as the first chair, while its legs are made of anthracite-colored lacquer material. The sideboard has gold-colored metal legs covering most of the mass, with the cabinet and drawers covered in white lacquer. As for the tables, the first one has a black metal leg and a top table with an elegant gold metal frame surrounding a smoky glass surface. The other two table models have gold metal legs, with the tabletop of one being circular and the other being square, both made of gold metal and anthracite compact laminate material. Seaden Quality Hotel's Italian restaurant includes 3 types of chairs, 1 type of bench, 1 type of sideboard, and 3 types of tables. Two of the chairs share a brown leather fabric and black lacquer legs; one has a striped pattern on the backrest, while the other has a diamond-shaped pattern. The third chair has the same model as the brown patterned chair but features white leather fabric. The bench has vertical stripes on the backrest and is entirely covered in white fabric, with gold metal legs similar to the chairs. The sideboard is entirely made of walnut veneer wood, while all tables have gold metal legs, with tabletops made of black marble and gold metal frames. The tables vary in size and shape. Diamond Deluxe Hotel's Italian restaurant offers 2 types of chairs, 1 type of bench, 1 type of sideboard, and 1 type of table. The first chair has a black leather exterior, a white fabric interior, and gold metal legs. The second chair is entirely covered in white fabric, featuring gold metal legs similar to the first chair. The bench is completely covered in white fabric, with gold metal legs. The sideboard is gray lacquer, with black metal handles on the drawers. The table has a white marble top and gold metal legs. Bella Resort Hotel's Italian restaurant provides 3 types

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

of chairs, 3 types of benches, and 2 types of tables. Two chair models share the same gold metal frame design, with one covered in white fabric and the other in green fabric. The third chair model has a bronze metal frame and is covered in brown leather fabric. The benches feature tufted backs and walnut legs, available in green, red, or white fabric. One table has a white marble top with a gold metal border and legs, while the other table has a brown solid wood top and gold metal legs. Narcia Hotel's Italian restaurant offers 2 types of chairs, 1 type of bench, 1 type of sideboard, and 2 types of tables. The first chair has a brown fabric with a baklava pattern and gold metal legs, while the second chair has a gray concrete-textured fabric with wooden legs. The bench has a turquoise fabric for both the seat and backrest, with oak veneer wooden legs. The sideboard is white lacquered with black metal handles. One table has white lacquered top in a square shape, and the other has a white lacquered hexagonal top with ethnic patterns on the front (Figure 13).

Figure 13. Movable Furniture From A'la Cartes

3.2.2. Accessory as a Spatial Element

Mylome Resort Hotel's Italian restaurant features a welcome desk adorned with a gray metal object composed of rings, two different forms of smoky-colored glass vases, and another vase in gold metal. On the walls, two identical abstract paintings with earthy tones, blue, and white colors are displayed. Seaden Quality Hotel's Italian restaurant includes a mirror known as the "Venice Mirror" with a green curtain and a console table featuring a bronze-framed mirror and a lamp with an anthracite-colored shade. In Diamond Deluxe Hotel's Italian restaurant, an accessory depicting a different interpretation of Leonardo Da Vinci's wing model is hung on a white brick wall. Bella Resort Hotel's Italian restaurant showcases accessories like Galileo Galilei's telescope and paintings combining the Renaissance-era male fashion of goats, which were commonly found in Italy's mountainous regions. In Narcia Hotel's Italian restaurant, accessories include a crystal chandelier-shaped painting on the wall and paintings of women blended with green plant textures. These accessories contribute to the unique ambiance and thematic elements of each restaurant (Figure 14).

4. CONCLUSION and RECOMMENDATIONS

The concept of authenticity in ethnic restaurants can vary depending on the cultural characteristics they aim to reflect. In the case of the first restaurant analyzed, Mylome Resort Hotel's Italian restaurant, it maintains a modern language while incorporating certain cultural references that define the authenticity of the space. Despite its modern approach, specific cultural cues within the restaurant contribute to its sense of authenticity. Similarly, the Italian restaurant in Seaden Quality Hotel, the second restaurant examined, shares similarities with Mylome Resort Hotel. This modern restaurant also incorporates elements like metal wrought-iron-textured wooden panels resembling Italian church architecture and the use of an iconic accessory like the "Venice Mirror" to convey authenticity. In contrast, the Italian restaurant within Diamond Deluxe Hotel, the third restaurant reviewed, distinguishes itself from the first two. In this space, where colors and material diversity are relatively sparse, elements like lake-coated panels resembling Ancient Greek columns and drawings related to Leonardo Da Vinci and his works on white bricks contribute to the perception of authenticity. Bella Resort Hotel's Italian restaurant, the fourth restaurant analyzed, stands out as the most diverse in terms of color, texture, and accessory variety, despite having modern lines. The fusion of the goat, commonly found in Italy's mountainous regions, with Renaissance-era male fashion on canvas, along with elements like black bricks on the ceiling and earth-toned ceramics on the floor, enhances the sense of authenticity. The Italian restaurant within Narcia Hotel, the fifth restaurant examined, appears fundamentally different from all the others. While it incorporates modern elements, the overall design emphasizes an ethnic feel through its texture and colors. However, the complete detachment from contemporary design trends raises questions about

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

whether the space might be overly commodified. The term "authentic" implies adherence to local or original characteristics, and while many restaurants aim to capture this essence, the study reveals that each restaurant incorporates authentic elements in its own way. It is important to note that the pursuit of authenticity in restaurants can sometimes lead to commercialization, even though the intention may be to create authentic dining experiences.

ABSTRACT

Despite the fact that the covid-19 period ended with taken measures, it was referred as the "new normal" period because of the awareness and habits it created. Among the sectors most affected during the pandemic, restaurants were the establishments that experienced the most significant changes. In the scope of this study, concepts from the literature before the Covid-19 period were investigated to determine important parameters for restaurant designs. New parameters and user expectations that were introduced during the pandemic and either permanently or temporarily observed, depending on the continuity of the measures taken, were evaluated. A retrospective approach was employed to systematically present the process that restaurants underwent after the first Covid-19 case in Turkey. It was found that concepts such as social distancing, contact reduction, and hygiene, which were frequently mentioned during the pandemic, influenced the spatial layout of restaurants. Given the importance of hygiene, which has become an expectation due to new habits brought about by the pandemic, and the increased emphasis on natural ventilation, there is a need to increase the use of open and semi-open spaces. However, the concept of social distancing was not as crucial during the post-pandemic period and did not persist as a permanent habit. The proliferation of contactless transformations in restaurants, such as cloud kitchens, was also observed. In conclusion, the parameters from the pre-pandemic period and the new concepts that emerged were evaluated together. Recommendations were provided regarding the criteria that should be considered in restaurant designs during the post-pandemic 'new normal' period.

Keywords: Post Covid-19, New Normal, Restaurant.

1. INTRODUCTION

The Covid-19 (SARS-CoV-2) virus, which leads to Severe Acute Respiratory Syndrome, was recognized as a global pandemic with a confirmed case count exceeding 600 million (Dong, Du, Gardner 2020). Following the declaration of a pandemic by the World Health Organization (WHO), many governments implemented significant mobility restrictions (isolation, social distancing, travel bans, quarantine, etc.) in order to prevent the comprehensive and rapid spread of the disease, which had a significant impact on the global economy (Nicola et al. 2020). As a result of all these measures, restaurants suffered from a decrease in consumer traffic (Sedov 2022). During the period of curfews, mandatory mask usage, restrictions on intercity travel, and social distancing measures, there were changes in individuals' attitudes and behaviors.

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

According to Karataş (2020), in Turkey while there has been an average increase of 85-90% in behaviors involving protective measures such as cleaning, hygiene, and the use of masks and gloves due to the Covid-19 pandemic, there also has been a 95% reduction in being in crowded places. Crowding is a crucial factor in consumers evaluating a restaurant's popularity (Tse et al., 2002). However, during the pandemic, crowding is far from the concept of a safe restaurant environment. When restaurants reopened after mandatory closures, they had to implement social distancing measures to ensure the safety of both employees and customers. In order to mitigate the negative effects of the pandemic, various research studies developed implementable solutions. Some of these solutions were mandated by the government, while others were strategies devised by restaurant owners to sustain their businesses. However, it was uncertain how consumers would react to these measures. According to one study, consumers showed different likelihoods of visiting restaurants that placed partitions between tables compared to those that created separate dining room sections. Additionally, the preferences of different age groups varied depending on the measures taken (Taylor Jr., 2020). In the "new normal" introduced into our lives after the pandemic, some of the measures taken have become a part of our lives temporarily, while others are permanently. Looking back, the measures taken and the parameters that need to be evaluated in restaurant settings going forward were discussed within the scope of this study.

2. Temporal Analysis of Measures Taken in Türkiye During the Covid-19 Period

The first Covid-19 case in Turkey was confirmed on March 11, 2020 (Republic of Turkey Ministry of Health, 2020). The initial measure taken by the Ministry was the temporary suspension of primary and secondary education for one week, and tertiary education for three weeks, starting on March 12th. Subsequently, establishments such as bars, nightclubs, theaters, cinemas, and other entertainment venues were temporarily closed. The escalation of preventive measures commenced following the first Covid-19-related fatality on March 17, 2020. The Ministry of Interior, issued a circular mandating that all dining establishments, whether serving alcoholic beverages or not, were to exclusively provide takeout and delivery services, with no permission for on-site dining, on March 21, 2020. The "Stay at Home" campaign was initiated to minimize interpersonal interactions, with the objective of curtailing the transmission rate. For the duration of the pandemic, vulnerable demographic groups such as individuals aged 65 and older and those with chronic health conditions were subjected to restricted outdoor mobility as a precautionary and preventive measure. As of April 4th, individuals under the age of 20 were also encompassed by these restrictions. This period persisted until May 10, 2020, following which specific hours of freedom were granted, contingent upon adherence to designated distancing measures, such as only visiting locations within walking distance from one's residence. In April, international travel restrictions were universally introduced to manage the impact of the Covid-19 pandemic on public health and to effectively govern the rate of contagion. In Turkey, these restrictions were enforced on an intercity level, commencing from April 3, 2020.

As of May 17, 2020, with the commencement of a phased normalization process, the Ministry of Health, the Ministry of Agriculture and Forestry, and other relevant institutions and organizations in Turkey issued circulars and general principles in line with the recommendations of the Centers for Disease Control and Prevention (CDC) to prevent the spread of the disease. Guidelines were established emphasizing the importance of people staying away from enclosed spaces as much as possible. However, when it was necessary for

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

individuals to gather in such spaces, guidelines were provided regarding mask usage, social distancing measures, and hygiene precautions (URL-1).

As a result of these measures, cafes, restaurants, sports facilities, parks, and other places were gradually reopened with time limitations and specific usage rules. Restrictions on intercity travel were also lifted. On June 10, 2020, restrictions for individuals under the age of 18 and those aged 65 and above were eased. The operating hours of restaurants, cafes, and similar establishments were extended. After five months of gradually easing measures and restrictions, it was announced on November 17 that education would continue remotely, weekend curfews would be imposed for all age groups with hourly limitations on outings, restaurants would only provide takeout services, and shopping centers would operate during specified hours (url-2).

On January 13, 2021, the first coronavirus vaccine arrived in Turkey and received emergency use approval, administered to the Minister of Health, Fahrettin Koca (URL-2). According to data from the Ministry of Health, the rate of first-dose vaccination in Turkey was determined to be 93.36%. With the widespread vaccination effort and following a two-week partial lockdown imposed on April 14, followed by a full lockdown, Turkey began to return to normal life on July 1, 2021. After approximately a year, on March 2, 2022, the mandatory mask usage requirement in public transportation was lifted, marking the conclusion of pandemic precautions (Table 1).

Table 1. Turkey's COVID-19 pandemic timeline

1	The first Covid-19 case detected in Türkiye	March 11, 2020
2	Suspension of primary and secondary education for one week, and tertiary education for three weeks	March 12, 2020
3	Closure of bars, nightclubs, theaters, cinemas, sports facilities, and other entertainment venues	March 15, 2020
4	First Covid-19-related death reported, cessation of mutual flights with the UK, Switzerland, Ireland, Saudi Arabia, the United Arab Emirates, and Egypt	March 17, 2020
5	Curfew imposed for citizens aged 65 and above, initiation of the "Stay at Home" campaign, and decision for restaurants to provide only takeout services	March 21, 2020
6	Ban on entry and exit for 15 days to 30 metropolitan cities and Zonguldak	April 3, 2020
7	Curfew for individuals under the age of 20	April 4, 2020
8	Weekend curfew implemented for the first time (30 metropolitan cities and Zonguldak)	April 11-12, 2020
9	Official holidays combined with weekends, resulting in a total of 4 days of curfew	April 23, 2020
10	Announcement of the normalization calendar by the Presidency	May 4, 2020
11	Commencement of phased normalization	May 17, 2020

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

12	Reopening of venues such as cafes, restaurants, coffeehouses, sports facilities, swimming pools, thermal baths, and parks with specific rules and time limitations, as well as the lifting of intercity travel restrictions	June 1, 2020
13	Easing of curfews for individuals aged 18 and under and those aged 65 and above, and extension of operating hours for restaurants, cafes, and coffeehouses	June 10, 2020
14	President announced that education would continue remotely, weekend curfews would be imposed from 10:00 AM to 8:00 PM, restaurants would provide only takeout service, and shopping malls and markets would close at 8:00 PM	November 17, 2020
15	First Covid-19 vaccine administered	January 13, 2021
16	Implementation of a 2-week partial lockdown	April 14, 2021
17	Full lockdown	April 29 to May 17
18	Return to normal life	July 1, 2021
19	Mandatory mask usage lifted	March 2, 2022

In the process marked by quarantine decisions, curfews, travel bans, and stay-at-home campaigns, the food and beverage sector emerged as one of the hardest-hit industries. Restaurants (Goddard, 2020), faced with issues such as workforce losses due to employee illness, disruptions in supply chains, a decrease in customers due to pandemic concerns, and the consequent inability to achieve sufficient sales, had to adjust in their current operations (Kocaman et al., 2021). Some of these adjustments were mandated by government ministries as compulsory measures, while others were implemented as strategic methods and ideas adapted by restaurants in their efforts to survive.

2.1. Mandatory Measures Taken in Restaurants

According to the Ministry of Health guidelines, following the commencement of customer acceptance by food and beverage establishments with the gradual normalization directive as of May 17, 2020, a series of mandatory measures were mandated. Establishment operators, as outlined in the directive sent to all 81 provinces (url-3), are obligated to adhere to these rules/practices throughout the entire facility. One of the necessary measures is the preparation of a social distancing plan regarding widespread use areas and seating arrangements. Restaurants have determined their customer capacity based on this plan, and this capacity information is displayed in a visible location at the facility's entrance. Additionally, panels containing the measures implemented in the facility and the precautions that must be followed have been arranged in widespread use areas easily visible in the facility's entrance hall or exterior facade (Figure 1).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 1. Seating arrangement after capacity limitations

Customer entry into the establishment involves the use of a thermal camera or contactless temperature measurement. Customers with a temperature measurement exceeding 38 degrees Celsius are not allowed into the restaurant and are advised to seek medical attention. Furthermore, hand sanitizers or cologne are provided at entrances to ensure customers' hand hygiene before entering. Customers without masks are not accepted, and if they do not have masks, restaurants provide masks.

Within the restaurants, dining areas, entrance areas/lobbies, additional rooms, restrooms, any designated smoking areas, and open spaces, including the entire facility, have been arranged in compliance with the social distancing plan. Social distancing signs have been placed both for seating arrangements and in areas where queues may form to maintain the required distance.

The seating arrangement of tables and chairs has been rearranged according to distance rules. The distance between tables is set at 1.5 meters, and the distance between chairs placed side by side is 60 centimeters. When tables need to be combined for larger groups, the distance requirement is maintained without compromise. Placing chairs at the same table or a crowded seating arrangement is not allowed. In tables with a narrow side less than 70 cm wide, a diagonal seating arrangement is applied to increase the distance between customers sitting across from each other. In bar table arrangements where customers sit side by side, the distance requirement is set at 1 meter. The use of tables where staff and customers face each other directly is prohibited.

If there is a buffet service in the restaurant, plexiglass or similar barriers have been placed between the buffet and customers to protect against contact. Similarly, devices such as tea and coffee machines, water dispensers, and beverage dispensers have been removed to minimize person-to-person contact, and their service is now provided by staff.

Cleaning and disinfection after each use is required for dining tables, chairs, and all materials that customers may come into contact with (tableware, salt and pepper shakers, condiment containers, napkin holders, menus, etc.). It is preferred that items for shared use, such as salt and pepper shakers, and condiment containers, be provided as single-use items if possible. One of the items requiring disinfection after each use is the payment device. It is recommended to

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

sterilize it with a cleaner containing at least 70% alcohol, and contactless payment methods are preferred when possible.

In addition to providing hand sanitizers at the entrances to public restrooms in restaurants, it is recommended that entrance doors be replaced with automatic door systems if possible. If not, it is mandatory to ensure the continuous cleanliness of entrance doors. Floors, toilet bowls, urinals, sinks, and faucet handles must be cleaned with bleach. Furthermore, in restrooms, hand dryers have been disabled, and single-use paper towels have been introduced.

Indoor children's play areas in restaurants have been closed. Outdoor areas have been left open, provided that they are cleaned frequently, but the presence of small materials and toys that cannot be continuously cleaned has been prohibited. Materials that could involve extensive hand contact, such as game pieces and cards, have been prohibited due to the elevated risk of transmission (Ministry of Health, 2020).

2.2. Non-Mandatory Measures Taken in Restaurants

During the Covid-19 pandemic, in addition to the mandatory measures implemented by the government, restaurants took their measures to cope with the pandemic and adapt to it (Alonso et al., 2020). Many studies suggest that these methods developed to minimize the crisis's impact may become a standard part of the industry in the post-pandemic era (Kim et al., 2020; Lane, 2020; Breier et al., 2021). Indeed, many technological transformations implemented by restaurants during the pandemic may continue beyond it. One such example is contactless payment methods. Due to concerns that cash could be a source of transmission during the pandemic, the use of digital money, mobile wallets, and contactless cards for touchless payments rapidly became widespread. Additionally, digital menus, often accessed via QR codes placed on dining tables or placemats, gained popularity (Özen & Akpınar, 2022). Beyond QR codes, interactive restaurant tables, which offer not only digital menus but also order recommendations, allow customers to place orders without assistance and even watch their orders being prepared in the kitchen. However, this system has not been widely adopted due to its cost and the high likelihood of accidents like liquid spills (Echtler & Wimmer, 2013; Tursan, 2021). Another technology used without the need for staff is self-service kiosks for ordering and payment. These kiosks are easy to clean and offer contactless options such as biometric recognition and voice ordering, making them increasingly popular (Özen & Akpınar, 2022).

In the context of contactless dining options, cloud kitchens have gained significant attention during the Covid-19 pandemic. Also known as dark kitchens or ghost kitchens, cloud kitchens have become a trend (Kulshreshtha & Sharma, 2022). These kitchens are specialized in food delivery and lack physical dine-in areas or storefronts. Some cloud kitchens are shared and rented by multiple restaurants (Hakim et al., 2022). These establishments do not have a physical dining area to host customers; orders are placed online, and deliveries are made through takeout or delivery services. The pandemic accelerated the growth of this concept due to restaurant closures and safety concerns (Ruiying Cai et al., 2021).

Customer safety concerns have also influenced consumers' restaurant selection criteria. For example, research suggests that private dining rooms in restaurants have been preferred because they make customers feel safer (Güngör, 2020; Tse et al., 2020). Many restaurants have made customizations in response to this trend, such as partitioning dining areas with glass or plastic materials to prevent contact with other customers. Similarly, temporary measures have been

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

taken with materials like plexiglass to reduce contact between customers. These barriers can divide spaces between tables and, in some cases, even separate individuals at the same table, creating isolated environments.

According to studies measuring customer behavior through survey-based methodologies (Ziberzani et al., 2022; Siddiqi et al., 2022; Kastromitina et al., 2021), the hygiene measures implemented by restaurants during the Covid-19 pandemic have changed behavioral responses. Brandau (2020) found that regularly and visibly cleaning tables, kiosks, and other touched surfaces, as well as employees wearing food safety-appropriate attire, were among the most effective ways to make restaurant customers feel safe. Some restaurants have also improved their hygiene measures to strengthen the relationship between hygiene and trust. In addition to adhering to the recommendations of the Centers for Disease Control and Prevention (CDC) and the Health Ministry's working guide, measures such as improving the ventilation system, using antibacterial materials, and implementing touchless doors and faucets have been taken to enhance hygiene and customer confidence.

3. METHOD

In the study, spatial concepts influencing restaurant choices in the post-Covid-19 'new normal' life were examined. The universe of the research consists of parameters related to space. A "purposive sampling" method was used for sampling. According to this method, suitable groups, factors, units, etc., are determined in accordance with the purpose of the research (Büyüköztürk et al., 2011). The sampling process was conducted in three stages. In the first stage, to determine the parameters affecting the space before the Covid-19 period, the main keyword "restaurant" was used to search Google Scholar, WOS, Science Direct, and DergiPark. Then, studies focusing on the space for restaurants were filtered, and suitable studies were selected based on accessibility, scope, and research purpose criteria. In the final stage, prominent concepts related to restaurants were identified using the keywords "Covid-19; restaurant".

Additionally, a retrospective approach was applied in the research. The term "retrospective" comes from the French word "rétrospective," which means "from the past to the present" (TDK). In the Cambridge dictionary, the retrospective is translated as "related to or thinking about the past" in general terms. In scientific research, it has been used as a method in many fields. In the medical field, this concept is used as a data collection technique. If groups of patients with common characteristics are examined retrospectively towards the past, a retrospective study is conducted. Researchers collect retrospective information to investigate cause-and-effect relationships (Çaparlar & Dönmez, 2016). Retrospective diagnosis is the process of determining a disease after the patient's death. This also includes interpreting unknown causes of death in history or ambiguous diseases in society as contemporary events (Burnham, 2005). The retrospective method is an evaluation of what has been done before in software development. It questions what went well, what did not, how it can be improved, what did not work, or what will be done differently next time (Jovanovic, 2016). In the field of art, it is a method that presents the past works of an artist with details such as the artist's stages, periods, changes in style, etc. (Ayan, 2013).

In summary, the retrospective method, applied in various fields with different perspectives, has been used in this study to provide a systematic view from the past to the new normal. It observed the sustainability of criteria that entered our lives during the pandemic in restaurant spaces

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

before the pandemic. In the period before Covid-19, the literature related to restaurants was associated with concepts such as ambiance, spatial layout and functionality, flexibility, signs and symbols, facility aesthetics, materials, and services. During the Covid-19 period, concepts of social distancing, hygiene, and contact were added (Figure 2), and their relationships were evaluated with a retrospective approach.

Figure 2. Prominent concepts in restaurants before and after Covid-19

The addressed concepts pertain to restaurant architecture, spatial arrangements within restaurants, spatial narratives, interior design, decoration, and criteria influencing design decisions. The explanations of these headings, their contents, and references are presented in the "Findings" section.

4. FINDINGS

The extended duration and widespread impact of the Covid-19 pandemic, posing a significant threat to public health, led to the implementation of quarantine measures, travel restrictions, and various regulatory policies by governments worldwide. These measures resulted in significant changes in the services and establishments, not limited to Türkiye but on a global scale, particularly within the restaurant industry. When scrutinizing the chronological aspects of the Covid-19 measures enforced in Türkiye, which encompassed restrictions affecting restaurants, it is discerned (Figure 3) that from March 21st until June 1st, only takeout services were authorized. It was only after the widespread distribution of vaccines and the commencement of the "new normal" phase that restaurants resumed their operations, albeit with specific regulations and constraints in place.

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

Figure 3. Restaurant process during the Covid-19 Period

When conducting a literature review, seven main headings related to restaurant spatial parameters that existed before the Covid-19 period have been identified. These headings are ambiance (Bitner, 1992; Ryu, 2005; Waxman, 2006, etc.), spatial layout and functionality (Bitner, 1992; Ryu 2005, etc.), flexibility (Oxman, 1975; Yürekli, 1983; Forty, 2000, etc.), signage and symbols (Bitner, 1992, etc.), facility aesthetics (Wakefield and Blodgett 1999, Ryu 2005, etc.), materials (Bitner, 1992; Galip & Gültekin 2015, etc.), and the service provided (Fathy, 1992; Ryu, 2005, etc.).

Ambiance refers to the background characteristics that tend to influence the environment. These characteristics can have abstract sensory and subconscious effects (Ryu, 2005). These background conditions include temperature, air quality, lighting, noise, music, and scent (Baker, 1987; Bitner, 1992). During the Covid-19 period, natural ventilation became crucial in this parameter. Indoor spaces were frequently ventilated naturally by opening doors and windows, and if air conditioning was used, proper maintenance and sterilization were necessary measures.

Spatial Layout and Functionality encompass the arrangement methods of furniture and equipment, which include their size, shape, and relationships between them. This arrangement should align with the needs of the service delivery process (Bitner, 1992). As of June 1, 2020, the reopening of dining establishments adhered to specific rules, with social distancing measures playing a crucial role in spatial organization. Distances between tables and customers were pivotal in establishing the spatial layout. The Ministry of Health defined suitable distances between tables, chairs, and bar setups and imposed seating capacity limits. Measures were taken to ensure That there was no direct face-to-face contact between service personnel and customers in bar setups (Figure 4).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 4. Restaurant seating and bar arrangement

As part of non-mandatory measures, the creation of private seating areas by completely separating each table from each other aimed to establish a sense of safety in restaurants by creating isolated spaces. These measures were mostly observed in the outdoor areas of restaurants in Türkiye (Figure 5). Seating areas created in the form of private rooms using transparent materials continued to be used even after the pandemic due to their ability to provide protection in various weather conditions such as rain or snow and their appeal as a unique space.

Figure 5. Private dining rooms

Flexibility is a concept that establishes a dynamic relationship between the environment, technology, function, and alternative designs or multipurpose use according to changing conditions (İslamoğlu & Usta, 2018). During the Covid-19 period, in addition to mandatory social distancing rules, restaurants experimented with alternatives to minimize the risk of transmission by implementing flexible structures that could be assembled and disassembled according to their own preferences. In this context, separators created using transparent materials such as plexiglass and glass were frequently preferred. These separators could separate two tables or serve as a protective measure for individuals sharing the same table (Figure 6).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 6. The separators used to prevent transmission

Signs and symbols include directional signs displayed inside or outside the facility, warning signs containing behavioral rules, and promotional signs and symbols of the facility's brand (name, logo, etc.). Social distancing signs were expected not only in the dining area but also in all areas of the restaurant (elevator, restrooms, payment counter, etc.). Both restaurant staff and customers were expected to adhere to the distance that varies between 1.5 to 2 meters (Figure 7).

Figure 7. Social distancing signs

Facility aesthetics refers to architectural design, interior design, and decorative elements that contribute to the attractiveness of the physical environment. In restaurants, it is considered a marketing tool that can influence consumer attitudes, price and value perceptions, satisfaction, and behaviors (Ryu & Han, 2009). During the pandemic, restaurants offered creative ideas to make pandemic measures aesthetically pleasing. Open kitchen designs, stylish dividers, and socially distanced custom-designed rooms, which allowed customers to witness safety and hygiene rules, continued to be preferred mostly in luxury restaurants during the pandemic era.

The characteristics of the materials used and their relationship with other materials affect the effectiveness and enhancement of the space (Erçetin & Erdemir 2021). During the pandemic,

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

with the increased emphasis on hygiene, restaurants turned to the use of antibacterial and antiviral materials.

The services offered encompass the typology of the service to be provided and include services such as parking, children's play areas, and others. The formation of a fast-food establishment would not be the same as that of a luxury venue. Similarly, services to be offered such as buffet usage, parking facilities, and children's play areas, will affect the formation of the venue. During the Covid-19 pandemic, restaurants faced significant restrictions on their service standards. To reduce contact rates, the use of open buffets was suspended, and service was provided by service staff. In addition, to the use of shared items such as tea and coffee machines, and water coolers, service staff also managed beverage dispensers. Service personnel are required to wear masks. Some restaurants have also implemented protective barriers between staff and customers (Figure 8).

Figure 8. Service from staff rather than self-service at the open buffet

Similarly, the preventive measures imposed have led to the prohibition of children's play areas and gaming services provided by restaurants in order to prevent transmission through contact (Figure 9). With the lifting of these measures, these services have not been observed to become a part of the new normal in Türkiye.

Figure 9. Prohibitions on games

Non-mandatory measures in the scope of restaurants have led to technological transformations. Contactless payment methods, the use of QR codes in menus, and contactless kiosks have become widespread. Contactless transactions or the continuous cleaning of touched surfaces have become standard expectations for customers (Figure 10).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 10. Cleaning after each use

In the context of non-mandatory measures, restaurants have transitioned to using single-use paper towels instead of electric hand dryers in restrooms. However, this practice has been phased out in the new normal. Maintaining cleanliness in restrooms and regular cleaning remains an important criterion for space quality in the new normal. Additionally, in non-mandatory measures, restaurants continue to use transformed elements such as automatic sensor doors and sensor faucets. However, measures like providing hand sanitizers and cologne are no longer observed in the new normal (Figure 11).

Figure 11. Precautions were taken in restaurant restrooms during the Covid-19 period.

5. CONCLUSION and RECOMMENDATIONS

The Covid-19 pandemic had a profound impact on people's lifestyles, including their dining habits. As a result, changes occurred in food and beverage establishments. Prior to the pandemic, factors like ambiance, aesthetics, and functionality were highly regarded. However, during the pandemic, people became more concerned about their health. In response to this shift in consumer priorities, restaurants not only implemented mandatory measures but also took extra care to meet customer needs through strategies such as spatial reconfigurations, contactless features, and enhanced hygiene conditions.

These measures, whether consciously or unconsciously, raised awareness about the importance of concepts like "social distancing," "hygiene," and "contact." Bridges & Mitchell (2000) interpreted this increased awareness as consumers adapting to the new circumstances. When environmental changes occur, users tend to develop new habits, and these habits often persist. During the Covid-19 period, users indeed developed new habits and awareness (Gössling et al. 2021; Seth, 2020).

In this context, air quality became more critical than ever in creating the ambiance in restaurants in the new normal. Designs should facilitate natural ventilation in restaurants, and the necessity of open and semi-open spaces should be considered. Additionally, flexible spatial solutions that can adapt to changing conditions should be seen as essential spatial criteria. During the Covid-

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

19 pandemic, the increasing popularity of cloud kitchens and delivery services had an impact on the spatial organization of restaurants. Likewise, the growing emphasis on food safety and hygiene expectations led to the proliferation of open kitchen designs. In this context, restaurants should be open to innovative ideas when it comes to their spatial configuration and the services they offer. Restaurants underwent significant technological transformations during this period, with the adoption of practices like QR code menus, contactless payments, ordering systems, sensor-operated doors, faucets, and more. These technological advancements are sustainable features that can be continued in the new normal. The use of antibacterial and antiviral materials also became widespread during the pandemic, emphasizing the importance of material selection in restaurants. It is crucial for restaurants to evaluate their material choices not only for aesthetic purposes but also with a focus on hygiene, considering the heightened importance of this concept during the Covid-19 period.

In the new normal, as daily routines and habits have changed, there is a greater need for open and semi-open spaces that provide adequate ventilation solutions, flexible spatial configurations to adapt to changing conditions, and innovative ideas driven by technological advancements. Although the emphasis on social distancing may have diminished as restrictions eased, it is important to note that isolated spaces created for this purpose should contribute to the ambiance and concept of the restaurant or provide protection against weather conditions like rain or snow. Restaurants should consider these concepts as integral parameters in their spatial design. With the increasing availability of vaccines and the return to a new normal, it is crucial for restaurants to acknowledge that even though restrictions may have eased, customer awareness and habits have changed. Therefore, spatial changes and adaptations remain essential in response to these evolving dynamics.

ABSTRACT

The discipline of architecture represents the relationship between nature, humans and the built environment. As the effects of being intertwined with nature on human psychology and physiology have been realized, research on this relationship has increased and gained importance. In recent years, there have been disconnects in the relationship between nature and architecture due to factors such as the development of technology, the increase in urban density, and the dominant approaches in the design of the built environment. Building biology and the biophilic concept are solutions for the sustainability of this relationship. Criteria such as protecting natural areas, using recyclable building materials, saving energy, and rainwater harvesting should play an active role in architectural design. Within the scope of the study, these concepts and criteria, which support human health, quality of life and well-being, aiming for a harmonious and balanced architecture with nature, constitute the research problem as integrated design inputs. In this context, a classification for integrated design inputs is proposed. It is essential to consider these inputs in interaction with each other in the design process. It is thought that the classification of integrated design inputs in the nature-architecture relationship are values that architects and designers should use.

Keywords: Integrated Design Inputs, Building Biology, Biophilic Design.

1. INTRODUCTION

The relationship of humans with nature began with an instinctive need for shelter before architecture, enriched with the formation of civilizations and the development of social life, and has reached the present day. The most important milestone in this relationship in the historical process has been the Industrial Revolution. The standard mass production approach that appeared after the Industrial Revolution affected the discipline of architecture; in this case, buildings that ignored environmental values were built. With these unhealthy and uncontrolled constructions and migrations, environmental problems, crowded places, and physically and mentally damaged people have emerged (Güler, 2000).

The human desire for a safe built environment and for developments in all periods to be related to nature and biology has never been stronger throughout history (Akman, 2013). Especially towards the end of the 20th century, the relationship between nature and architecture and the questioning of this relationship has become one of the most important problems. The rapid increase in the human population, industrialization, increase in the amount of greenhouse gases

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

in the atmosphere, human desire to dominate nature, etc. have caused damage to the ecosystem and the natural environment (Emekci, 2021).

For this reason, architects have many different points to consider in the design of the built environment. Beyond the customer's property budget, safety regulations, etc., architects have a wide range of responsibilities such as energy efficiency requirements, healthy building design, and the use of recyclable building materials (Ece, 2018).

There have been many studies on the relationship between nature and architecture. Concepts such as organic architecture, sustainability, ecological design, biomimesis, biophilic design, etc. have rapidly gained importance on a global scale and research has been developed on these topics. All these concepts are based on the aim of achieving the highest level of human and environmental health.

This study aims to benefit from building biology and biophilic design concepts in the context of determining parameters that positively support human physiology, psychology, and behavior in the built environment. It would be correct to understand and answer the search for solutions to the problem of the nature-architecture relationship with the help of building biology and biophilic design. The aim of the study is to analyze existing criteria through these concepts and develop a classification that strengthens the connections between nature and architecture.

Figure 1. Building biology and biophilic architecture (XUL Architecture, 2022)

1.1. Building Biology

The building is an artificial environment that can respond to different needs of people, is designed within the natural environment, and can provide comfortable, safe and healthy environments for people. The built environment is an indicator of our mental development, health and social status. Building, human and nature are in direct interaction and for this reason, while buildings are designed for the needs of people, they should also be in harmony with nature. Buildings that are not designed in harmony with nature negatively affect people's comfort, health and well-being (Akman, 1990). For this reason, the concept of "building biology" is important in order to prevent building-related health problems.

The concept, which first appeared in Germany as "Bau-biologie", was formed by the combination of the words built and life. It is defined as the study of the holistic relationship between people, built and life. Building biology combines functionality in architecture with the integration of artistic aesthetics, health and eco-social aspects. It focuses on various subject

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

areas ranging from urban coexistence in ecosocial communities to interior spaces that support human well-being and health (Ece, 2018). Building biology is the teaching of the holistic relationships between the user and the environment; it is the branch of science that examines the effects of structures and spaces on human health. When the relationship between biological principles and settlement requirements cannot be established, the design becomes simplistic, soulless and irresponsible. Today, people spend 90% of their lives in closed artificial environments that conflict with the natural environment, making it necessary to design healthy structures for mental and physical illnesses (YBE, 2021). The qualities of the artificial environment such as walls, floors, ceilings, interior fittings, etc. need to be taken into account. It is important to apply the principles of architectural psychology in terms of space, color and scale in order to nourish the spirit, support healthy building designs and qualify for arts and crafts. To protect the natural environment, renewable and regional resources, renewable energies, energy-efficient and resource-conscious methods should be preferred and the use of environmentally harmful substances should be minimized (Ece, 2018).

This approach, defined as "Prudence for Health Risks", is common in communities where environmental awareness is important. Instead of being obliged to repair the environmental damages caused by the building and to treat the physical and mental illnesses it causes to human health; it requires designing a building that will protect humans and environmental health (YBE, 2021).

Building biology is a tool to evaluate our built environment with universal standards of health, social responsibility, sustainability and aesthetics. It helps us to lead healthy and lives in prosperity, respecting the natural environment. It focuses on human health, environmental sustainability and protective measures on the building; using a humane and ecological methodology that seeks to establish a balance between nature and architecture (Ece, 2018).

There are 25 basic principles of building biology (Fig.2), covering the building site, building methods, building materials, indoor climate, and how to deal with the environment, energy, and water. These principles are categorized under 5 main criteria; healthy indoor air, thermal and acoustic comfort, human-based design, sustainable-environmental performance, and socially connected and ecologically sound communities (Louise, 2020).

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

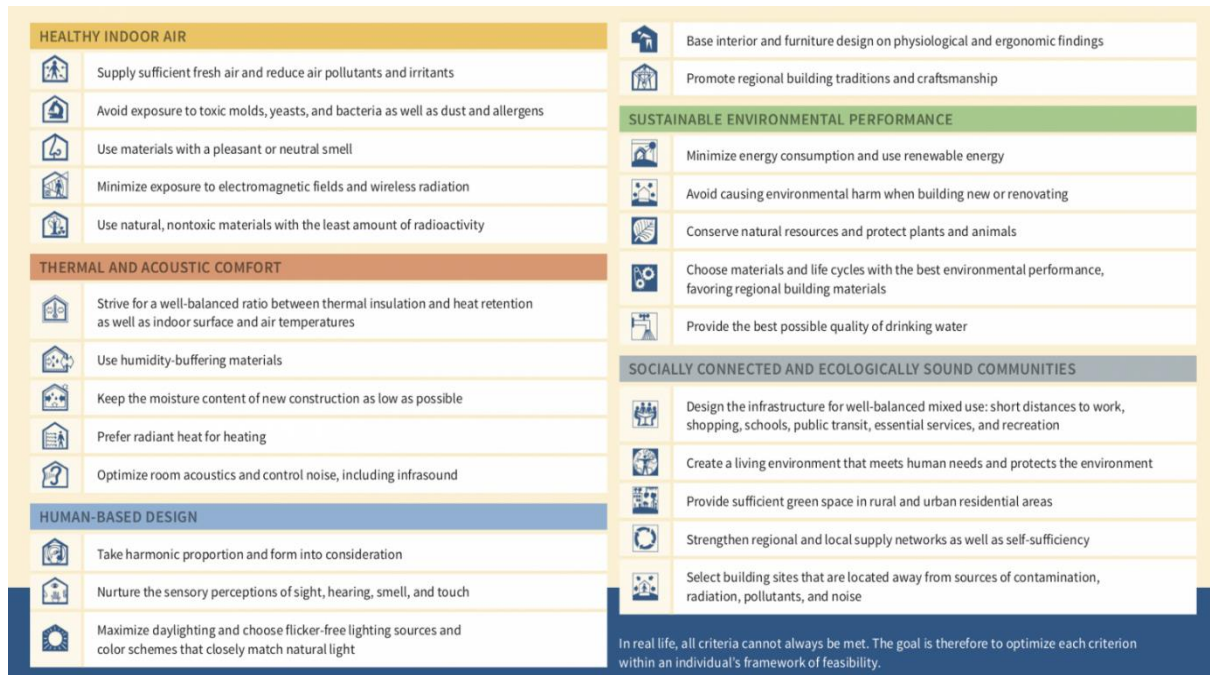

Figure 2. The 25 guiding principles of building biology (Louise, 2020)

In summary, building biology focuses on issues of the suitability of the building material, acoustic insulation, energy efficiency, air quality, human health-oriented indoor climate, psychological compatibility, water cycles and geological suitability of the construction area, etc. (Akman, 1999). Buildings designed based on the principles of building biology create a healthy indoor climate, are in harmony with their environment and fulfill ecological requirements that can meet user-community needs.

1.2. Biophilic Design

Biophilia is defined as people's need for nature for physical and mental health and their innate desire to be in touch with nature (Kellert, 2014). The concept, first mentioned by psychoanalyst Eric Fromm, means "love of life" (Akyıldız Arda, 2023).

Studies display that human well-being is connected to the natural environment and that human will need connections that strengthen their relationship with nature throughout their lives. For this reason, it is important to adapt the concept of biophilia to the architectural design discipline in order to create the connections that humans need in the physical environment.

The use of the concept and criteria of biophilia in architecture is defined as biophilic design. Biophilic design, which requires interdisciplinary work, argues that human health and well-being will be possible through the use of natural elements in architectural design, allowing human-nature interaction in the built environment to be sustained in a healthy way (İrfanoğlu and Suri, 2022). It supports the nature-architecture-human relationship and emphasizes the design of the built environment together with natural elements (Akyıldız Arda, 2023). It focuses not on minimizing negative human impacts, but on harnessing nature's ability to enhance human well-being in design (Grazuleviciute-Vileniske, Daugelaite & Viliunas, 2022).

Biophilic designs have many positive physical, mental and behavioral outcomes:

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

- Physical outcomes include lower blood pressure, increased comfort, fewer symptoms of illness, more health, and faster healing.
- Mental outcomes include increased motivation, less stress and anxiety, more creativity, and improved problem-solving skills.
- Behavioral outcomes include coping, increased concentration, improved social relations, and less aggression (İrfanoğlu & Suri, 2022).

There are 14 basic principles of biophilic design (Fig.3). These principles are categorized under 3 main criteria; nature in the space, nature analogue, and nature of the space (Browning, Ryan & Clancy, 2014).

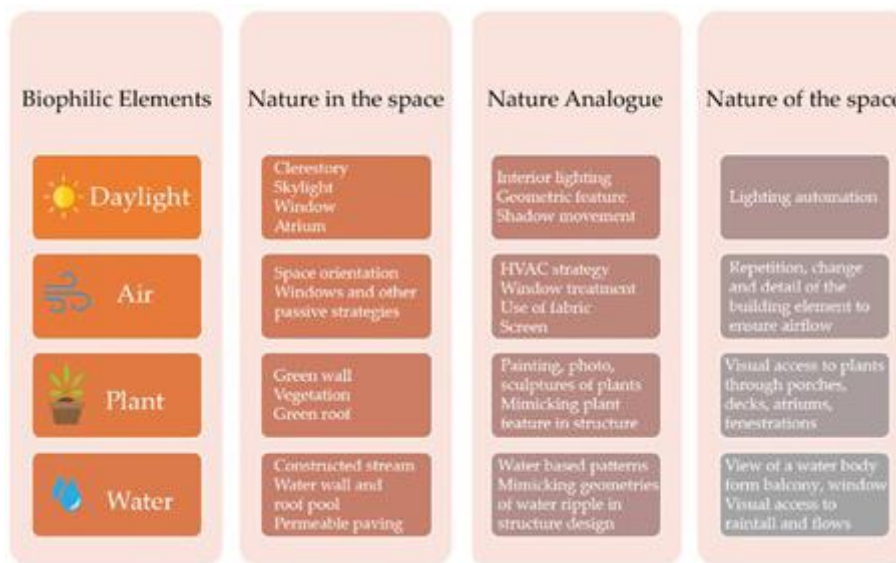

Figure 3. 14 Patterns of biophilic design (Nitu, Gocer, Wijesooriya, Vijapur & Candido, 2022)

The focus of biophilic design is the application of the sense of human evolutionary connectedness to nature in architectural design. Interacting with biophilic design criteria allows people to feel physiologically, mentally and psychologically well.

2. MATERIALS and METHODS

There are many practices and criteria under different categories in the nature-architecture relationship. In order to better perceive and systematize the possibilities provided by building biology and biophilic design approaches, it is aimed to develop a classification that explains the connections between nature and architecture. As a result of all these analyses, integrated design approaches in nature-architecture relationships have been developed. In addition, the potential of these approaches on the nature-architecture relationship has been evaluated.

3. FINDINGS and DISCUSSION

The lack of a general classification that explains and integrates all aspects of the criteria related to the nature-architecture relationship has been revealed. For this reason, a universal and systematic classification was made within the scope of the study. The inputs in the classification

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

are aimed to strengthen the connection and synergistic energy between the architectural design of the building and nature.

Integrated design approaches in the nature-architecture relationship are classified under 7 basic principles (Fig.4, 5); building materials, natural lighting, natural ventilation, acoustic comfort, energy-efficient building design, design according to the Earth's magnetic field, water efficiency - rain harvesting.

Figure 4. 7 Basic principles of nature-architecture relationship (created by authors)

1. Building Materials

Building materials constitute 20% of the negative environmental impacts caused by the built environment throughout its life. When selecting building materials, they must be recyclable and reusable (Emekci, 2021).

Criteria such as the amount of energy required during the production process of materials, their usability during the production process, their availability from local resources, production and application possibilities outside large facilities, their effects on personal health and the comfort level of the environment should be taken into account (Eriç and Ersoy, 1995). The selection of materials, especially according to sustainability principles, reduces the destruction of buildings in the natural environment, increases energy efficiency, reduces maintenance and repair costs, and creates healthy environments for users (Sev, 2009).

In addition, it is also important to use the selected building materials effectively and efficiently (Emekci, 2021).

2. Natural Lighting

Lighting is important for issues such as improving image quality, protecting eye health, and ensuring concentration. As a result of inappropriate lighting; eye fatigue, irritability, and headaches occur; quality of life and management productivity decrease.

Natural lighting, which is the most appropriate lighting, is realized by letting daylight into the space from the window or roof. In the use of daylight in lighting, attention should be paid to issues such as the light coming directly into the eyes and the presence of glare in the working environment (Güler, 2005).

In building design, the orientation of the building is important in order to benefit from natural lighting. Windows, which are the most important building element in natural lighting, should be designed for the climate in which the building is located. Building elements such as light tubes, light shelves, skylights, etc. can also be used to benefit from natural lighting (Emekci, 2021).

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

3. Natural Ventilation

One of the most important inputs in the nature-architecture relationship is the ventilation of spaces. In cities, the amount of CO₂, SO₂ and CO increases in the breathing air; in some buildings, materials release radon compounds and reduce the ions in the air by radioactive emissions. As a result, fatigue, breathing difficulties, weakened immune systems, and chronic and psychological diseases occur (Akman, 1990).

Air conditioning systems aim to achieve indoor air quality. ASHRAE (2001) standards define acceptable indoor air quality as particle levels that are in accordance with values determined by competent authorities and more than 80% of people are not disturbed by the air quality. Therefore, natural ventilation is important in buildings.

The aim of natural ventilation is to remove the polluted air out of the space by air circulation and to allow fresh air and oxygen to enter the space. Removal of polluted air is possible by circulating natural air within the building (Ersoy, 1994). Natural ventilation allows fresh air to enter the interior by expelling polluted air, balances the relative humidity indoors and removes hot air from the building when cooling is desired.

4. Acoustic Comfort

Noise is defined as a sound pattern that affects the physical, mental, and sociological health of people with the elements it contains. In addition to hearing problems, it can cause various diseases by affecting the nervous and cardio-vascular and respiratory systems (Güler, 2005). For these reasons, especially indoor acoustic comfort and sound insulation are important in architectural design.

Sound insulation can be achieved by coating the external wall of buildings with cladding materials, laying polystyrene-based materials under parquet and ceramic tiles, covering pipes with sound-absorbing materials, making double-glazing windows, crafted sound-absorbing ceiling and wall coverings, etc. (Ekinci, Işıksolu, Demirci, Ozan, İşçi ve Aydın, 2005).

5. Energy-Efficient Building Design

Energy-efficient building includes sustainability criteria related to human and environmental health. These criteria range from insulation level to indoor climate, from the use of radiant heat for heating to the use of renewable energy sources. Strategies such as the selection of appropriate systems, solar heat recovery, and conscious user behavior in heating and ventilation contribute to energy savings (Ece, 2018).

Energy efficient criteria in building design should be considered at all stages of design. Renewable energy sources such as solar, wind, sea, hydroelectric, bioenergy, geothermal, etc. found in nature, should be used as much as possible.

Energy efficiency should also be achieved through passive heating and cooling techniques (Emekci, 2021).

6. Design According to the Earth's Magnetic Field

Nature is dense with electrical and magnetic energies. Every energy has a magnetic moment. Human health can be negatively affected as a result of the effect of magnetic fields; it is known that cancerous cells can develop. It has been proven to have an effect on health issues such as tissue regeneration, body weight change, oxygen utilization, etc. For this reason, in building

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

design, attention should be paid to issues such as preventing ferromagnetic deformation, and preventing artificial magnetic alternating fields generated from electrical installations and electric vehicles (Akman, 2013).

7. Water Efficiency - Rain Harvesting

One of the most important resources of our biological earth is water. Water is consumed unconsciously due to problems such as global warming, uneven urbanization, environmental pollution, etc. This situation will bring drought.

In order to water conservation, water should be recycled and reused. In strategic landscaping practices, less need for irrigation can be achieved by using climate-appropriate landscaping.

In particular, collecting and utilizing rainwater is a current and important approach to water efficiency. By collecting the drops falling on the roof and facade, all the water needs of a building can be met (Emekci, 2021).

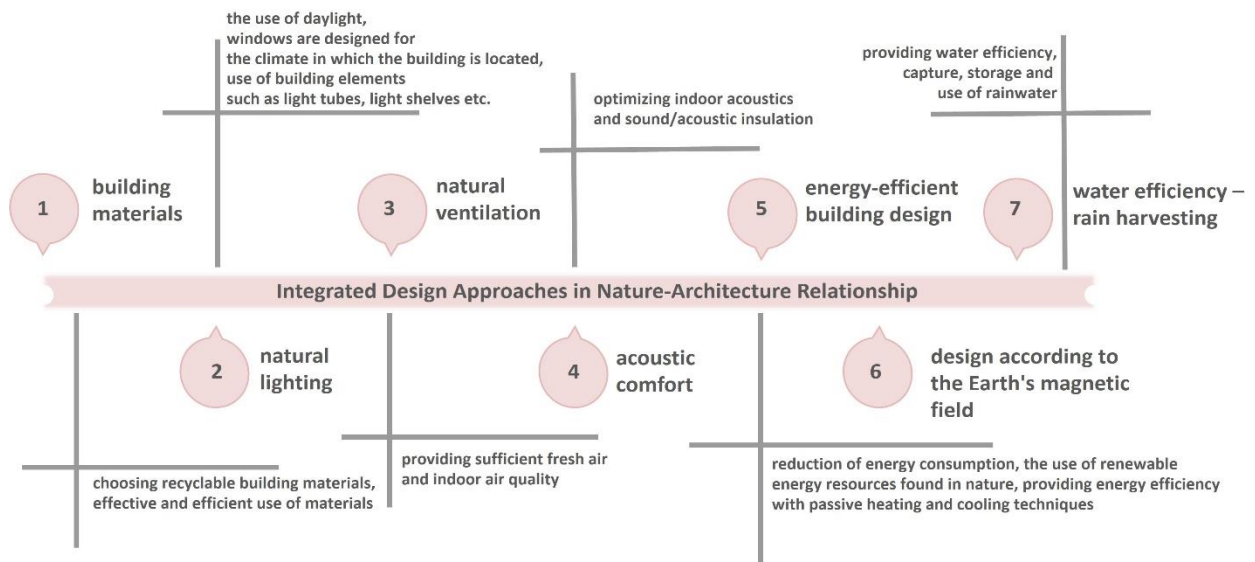

Figure 5. Integrated design approaches in nature-architecture relationship (created by authors)

4. CONCLUSION and RECOMMENDATIONS

In the nature-architecture relationship, design inputs that directly affect physical and mental health cannot be effective on their own. For this reason, it would be correct to approach the inputs mentioned in the study as integrated design inputs and to use them in architectural design.

These inputs, which include many issues such as urbanization, protection of natural areas, physical environmental control, energy efficiency, sustainability, rainwater harvesting, etc., when used in an integrated approach to design, will provide important contributions to current and future architectural problems and issues related to human physical, mental and behavioral health. The proposed integrated design inputs provide solutions for mechanical deformation, thermal factors, water and humidity effects, sound and noise problems, etc.

It is important to handle these inputs in interaction with each other in the design process. It is thought that the classification of integrated design inputs in the nature-architecture relationship are values that should be used by architects and designers.

ABSTRACT

Today, human beings have begun to pay the price for the natural resources they consume and damage, the environment they pollute, and cultural corruption. Especially environmental problems, climate change and its effects are the most important examples of this cost. Countries that are aware of the situation are looking for solutions and are in a hurry to take precautions. However, the solution does not seem easy at all. "Green infrastructure systems", produced as a nature-based solution to some of today's chronic and critical problems, constitute the main subject of this study. The aim of the study is to reveal the green infrastructure phenomenon in the sample countries (America, England, EU, Japan, China, India, Iran, Türkiye) examined. In the study, the green infrastructure phenomenon in the sampled countries was examined on the basis of corporate reports and projects, legislative documents and relevant literature. The findings showed that countries have differences in the institutional and legal structuring of green infrastructure, incentive systems, reflection on practice, and perception of scale. In conclusion, basic recommendations have been developed for the implementation of green infrastructure in all countries.

Keywords: Green Infrastructure, Open Green Spaces, Greenways, Urban Planning.

1. INTRODUCTION

The world population is increasing rapidly and more than half of this population lives in cities. Life in cities is becoming more intense every year. The figures reported by the United Nations, the World Bank and many other international institutions are not encouraging at all.

Although cities cover only 2% of the world, they consume more than two-thirds of the world's energy. It produces more than 70% of greenhouse gas emissions as the price of modern life. At the same time, cities are the growth engines of the world economy, enabling millions of people to escape hunger. If cities are planned well, world hunger and poor life can be further reduced. Unplanned and uncontrolled growth causes environmental problems, housing problems, increased crime rates, transportation problems, hunger, disasters, climate change, etc. causes (World Bank, 2023).

Today, cities consume enormous amounts of energy, produce mountains of garbage, require massive infrastructure investment, and are also the focus of poverty and disaster risk. This situation gets worse in cities where urbanization and population density are rapid, poverty is

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

high and planning is poor (UNDR, 2013). Climate change further triggers this situation in cities. Thus, cities play the role of the engine of the economy on the one hand, and the trigger of disaster on the other (Cities and Regions, 2023). Globally, annual losses from disasters in the built environment are estimated at \$314 billion. By 2030, this figure is expected to increase to 415 billion dollars. It is also estimated that more than 77 million people may be dragged into urban poverty (World Bank, 2023). In addition, future predictions say that the urban population exposed to hurricanes will increase from 310 million to 680 million in 2050, and those exposed to major earthquakes will increase from 370 million to 870 million (UNDR, 2013).

Cities are important to provide a better future for the world and humanity. Cities; sustainable, high environmental quality, resilient, fair, equitable, safe, etc. should be transformed into urban systems. The main subject of this study is "green infrastructure", which plays a key role in creating sustainable urban systems and is also considered an important tool in today's climate change fight and adaptation process. In the study, the current situation in the world is presented by examining the perception of GI within the scope of the sampled countries.

1.1. Green Infrastructure Concept and Its Importance

The seeds of Green Infrastructure (GI) were planted with the "green road" projects produced by Frederick Law Olmsted in the 1870s with the aim of connecting city parks. In 1903, Olmsted stated that "parks should be connected to each other and to the surrounding settlement to preserve biodiversity, prevent habitat fragmentation, and ensure equal access for people." Connecting the parks to each other started the modern greenway movement. The modern greenways movement has also influenced GI planning and implementation. It should also be noted that wildlife biologists and ecologists already know this situation for the continuity of ecological processes and biodiversity. Because "connectivity between open green spaces" is a key concept for conservation biology science and ecosystem management practices (Benedict & Machon, 2002). GI was used a "term" by local authorities in Florida in 1994 to refer to a natural and ecological system that is important in developing land conservation strategies. In addition it has been stated that it is as important as gray infrastructure (Firehock, 2010).

The President's Council on Sustainable Development, in 1999, identified GI as a strategic area that provides a comprehensive approach to sustainable social development. It has been stated that in the GI approach, ecological, social and economic functions are understood and ways to benefit from them are presented. The Council's 1999 report stated that "GI strategies actively seek to understand, exploit and value the different ecological, social and economic functions provided by natural systems, with the aim of protecting ecosystems as well as guiding more efficient and sustainable land use and development patterns." The Conservation Fund and the USDA Forest Service created the GI Working Group, which consists of government agencies and nongovernmental organizations. The group was convened to develop a program to help make GI an integral part of local, regional and state plans and policies. GI was defined for the first time within the scope of the studies.

The first definition for GI was made as follows; "*infrastructure is our nation's natural life support system—an interconnected network of waterways, wetlands, woodlands, wildlife habitats and other natural areas; greenways, parks and other conservation lands; working farms, ranches and forests; and wilderness and other open spaces that support native species, maintain natural ecological processes, sustain air and water resources and contribute to the health and quality of life for America's communities and people*" (Benedick & McMahon,

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

2002). Guided by this definition, there are many similar definitions of GI. However, this definition can be considered the most basic and general definition.

The terms “nature-based solutions”, “green infrastructure” and “natural infrastructure” are sometimes used interchangeably. The Environmental and Energy Study Institute in America expressed the difference as follows. Nature-based solutions are generally projects that incorporate natural features or processes into the built environment. GI, on the other hand, is generally expressed as projects that combine gray infrastructure with nature-based solutions to create hybrid systems that increase resilience to climate impacts. Natural infrastructure, on the other hand, are projects that use existing or reconstructed landscapes (e.g. forests, floodplains and wetlands) to increase resilience to climate impacts (NCSL, 2022).

Although GI and greenways have a common origin, GI and greenways differ from each other. These differences are (i) GI highlights ecology, not recreation (ecology and recreation) (ii) GI provides important landscape connections as well as ecologically important centers (large-small area) (iii) GI can shape urban form, direct growth (growth framework) (Benedict &McMahon, 2002).

In many studies, GI is considered a means of establishing “connections” between green spaces (Davies et al., 2015). However, this bond is a strategically planned bond with ecological-economic-social-cultural aspects and enables the creation of a network. It is also involved in public processes (Benedict and McMahon, 2002; McDonald et al., 2005; Benedict, 2006; Hellmund &Smith, 2006).

GI is a system of “hubs” and “links”. The system consists of natural and restored ecosystems and landscape features. Hubs anchor GI networks. It ensures the mobility of wildlife, in other words, it ensures the flow of energy. They are areas of continuity of ecological processes. There are cores in the middle of the hubs and they are very sensitive. Links connect the centers or the system (Figure 1). It keeps the GI networks functioning. Hubs and connections vary in size, function, and ownership. Long-term planning, management and protection are necessary for the success of the system (Benedict & McMahon, 2002).

Figure 1. GI network components (Benedict & McMahon, 2012).

GI systems promote ecological, social and economic benefits. These benefits include; health, agriculture and forestry, water management, education, tourism-recreation, disaster prevention

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

and management, combating climate change-adaptation, resilience, low carbon emissions and energy, land and soil protection, investment and employment, and increasing efficiency of natural resources. GI supports, strengthens and directs many different areas (Figure 2). These benefits ultimately help protect and restore ecosystems, in other words, support ecosystem services and sustainability.

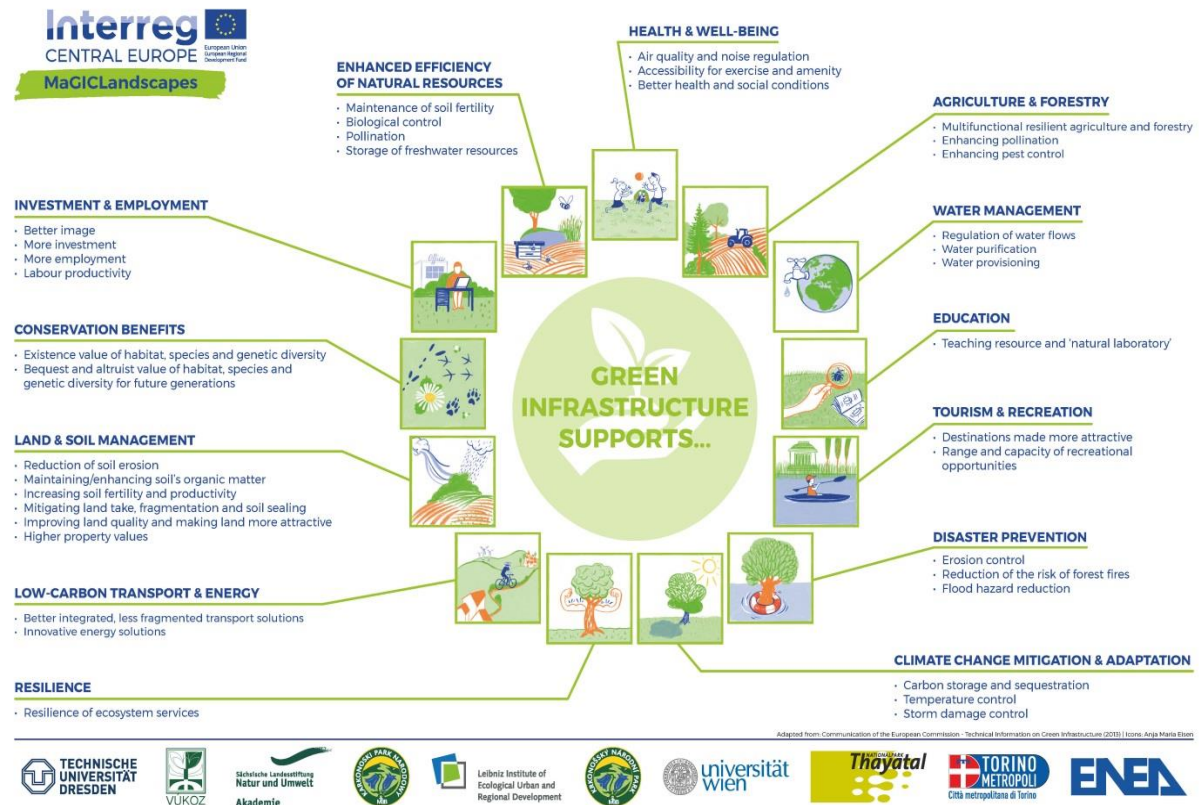

Figure 2. Benefits of GI (European Commission, 2013)

The GI system is planned based on various principles. These are expressed under 7 headings (McQueen & McMahon, 2003):

1. It should serve as the framework for conservation and development.
2. Planning and design processes should be established before development plans.
3. Links are essential components.
4. Must be able to multitask at different scales.
5. It should be constructed in line with land use planning theories and practices.
6. It is an important public investment.
7. Requires participation of various stakeholders.

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

1.2. GI Phenomenon in the World

United States (US)

GI was born in the United States with the planning philosophy of Frederick Law Olmsted. It guided the planning of cities in the USA in the 19th century (Benedict and Machon, 2002). Ian McHarg, who emphasized the development of cities on the basis of natural processes in the 1970s, nourished this approach. Philip Lewis, on the other hand, pioneered the protection of stream valleys and natural corridors in the urban planning process, actually emphasizing the importance of protecting GI components. New Urbanism movements, on the other hand, have nourished GI systems with the goals of protecting and developing open green areas (Parlak et al., 2022). Many urban planners and writers have developed and directed awareness in the USA by emphasizing the importance of open green spaces for the city.

There are different legal forces pushing the GI program in the USA. There are forces pushing the GI program in the USA. At the federal level, the "*Clean Water Act (1972), EPA Low Impact Development program (1990), EPA Innovative Wet Weather Grants (2005)* süreci yönlendirmiştir. Yerel düzeyde *Combined Sewer Overflow lawsuit (1991), Bureau of Environmental Services Sustainable Stormwater Division (2002)'nun kurulması, Water Quality Friendly Streets (2003), Watershed Management Plan (2006), Grey to Green Initiative (2008)* (Fukuoka & Kato, 2015).

Today, land in the US is being consumed and fragmented faster than ever before. Because the population is increasing rapidly and cities are expanding. Conclusion; loss of Natural Areas, Fragmentation of Open Spaces, Degradation of Water Resources, Decreased Ability for Nature to Respond to Change, Loss of Free, Increased Costs of Public Services, Natural Services Increased Taxes. Open green areas are constantly turning into residential areas and the protection of lands is an important problem (Benedict and Machon, 2002). The effects of extreme weather events are increasing day by day, and the priority of states is to reduce the effects of extreme weather events. States are increasingly adopting policies to develop, implement, and finance GI projects. They are integrating these projects into existing hazard mitigation plans. The federal government is also increasingly prioritizing disaster mitigation investments, and especially nature-based solutions. At this point, states have conflicting budget priorities. Additionally, pre-disaster mitigation investments/nature-based investments/GI investments compete with immediate response needs and other infrastructure concerns. On this subject, the nature-based National Institute of Building Sciences published a 2021 report showing that every \$1 invested in mitigation efforts provides a \$13 return on investment. This data is a powerful tool for states in determining spending priorities. The US Environmental Protection Agency estimates that improving stormwater and public wastewater systems across the country will require at least \$150 billion over the next 20 years. He states that GI systems can solve this problem. GI is viewed as a system that "*expresses landscape features and solutions that mimic, use or restore natural ecological processes.*" It is also emphasized that GI projects are "*an innovative approach to stormwater management that can protect water quality and increase a state's climate resilience*" (NCSL, 2022). The ecological-environmental, economic and socio-cultural benefits of GI systems are now recognized across many different sectors and platforms in US (EPA, 2023).

The main agency supporting GI in the United States is the United States Environmental Protection Agency (EPA). EPA defines the advantage of GI as "*Benefits of Green*

September 14-15, 2023, Naples, Italy

Infrastructure.” It also states that GI has 11 elements. These are “downspout disconnection, rainwater harvesting, rain gardens, planter boxes, bioswales permeable pavements, green streets and alleys, green parking, green roofs, urban tree canopy, land conservation” (Kida, 2017).

In the USA, GI is an issue that is emphasized on the basis of different scales. For example, it is often emphasized that GI produced at the basin scale makes the benefits for water quality more evident. For this reason, the importance of planning at the national/basin scale is emphasized (EPA, 2023). At the lower scales, state governments see GI systems as tools to meet public needs. Therefore, in order to meet land use and building requirements, the GI requirement has been accepted. In this context, landscape architects and urban engineering consultants provide expertise in GI design. Land owners and developers are also promoting GI aspects of local projects (ABA, 2023).

US GI policies focus on the state or municipal level, such as rebates, expedited permitting, grants and loans. In this sense, many projects have been implemented. Seattle, Chicago, New York are among them. Seattle is the first US city to manage stormwater runoff and improve neighborhood aesthetics (2006). The Seattle Green Factor (SGF) and the GI City Policy is the architect of Seattle. 2013 created a city policy to reduce combined sewer overflows through GI projects (*with bioretention swales, rain gardens, and green roofs*). A number of financial programs have also been developed for projects of different sizes. The most notable fiscal stimulus in Seattle has been tax abatement programs. The program offered “*tax breaks to property owners who install green roofs or on-site stormwater management systems.*” The program provided “*a 50% exemption on B&O taxes and a 75% exemption on city property taxes for up to 10 years.*” A “rebate program called RainWise that covers most or all of the rain garden installation” has been created for small areas. Additionally, “*Seattle's Priority Green Expedited Permitting Program*” was developed, offering a streamlined permitting process with a discounted fee for GI development projects. Thus, air-water quality in Seattle improved, greenhouse gas emissions decreased, active-sustainable transportation was encouraged, and the policies developed became a good example for other cities (Zakrisson, 2023).

GI is also reflected in federal and state legislation in the USA. This situation also increases the sanctions. For example, The Water Infrastructure Improvement Act of 2019, GI “*the range of measures that use plant or soil systems, permeable pavement or other permeable surfaces or substrates, stormwater harvest and reuse, or landscaping to store, infiltrate or evapotranspire stormwater and reduce flows to sewer systems or to surface waters*” (NCSL, 2022).

England

1873 British prime minister William Pitt considered the city's parks and squares the “lungs of London”. His comment can be considered the first political discourse on the GI system in the country (URL 2023a). Also, England has guided the urban planning journey in the light of urbanization approaches and political discourses in US.

Today, open green areas in England are the red line of construction policies (Tuna 2021). In this context, GI is instrumental for improving urban quality of life and creating climate-resilient towns and cities. The contributions of GI projects are evaluated under the headings of air quality, surface water management and water quality, biodiversity, health and welfare (Natural England, 2023).

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

The UK Government's natural environment advisor in England, "Natural England", is a follower of GI process (Natural England, 2023). GI has been supported by central government, Local Planning Authorities (LPA), the development sector and environmental advocates. Support from the UK government and its subsidiaries (i.e. Natural England, the Forestry Commission and the Environment Agency) has increased since 2005. Institutions responsible for GI are Community Forests, Local Planning Authorities (LPA), Environmental Organizations (i.e. Forestry Commission, Wildlife Trust), Friends/Community groups (Mell et al., 2017).

GI is also supported by legislation. It is working with the UK Department for Environment, Food and Rural Affairs (DEFRA) and other stakeholders to develop the "Green Infrastructure Framework", a commitment of the Government's 25 Year Agreement (Natural England, 2023). Community Forests, Local Planning Authorities (LPA), Environmental Agencies (e.g. Forestry Commission, Wildlife Trust), Friends/Community groups are responsible for GI (Mell et al., 2017).

There are national, regional and local policies on GI. There is the National Planning Policy Framework (NPPF) on a national scale, The Local Plan (GLA), Cambridgeshire Green Infrastructure Strategy, 2nd Edition on a regional scale and Liverpool Green Infrastructure Strategy (Mersey Forest) on a local scale (Mell et al., 2017).

There are impressive examples of GI. These; London Olympic Park, Chavesse Park (Liverpool), Great Fen Project (Huntingtonshire), Winter Gardens (Sheffield), Swansea Bay (Swansea), Herrington Country Park (Sunderland) (Mell et al., 2017).

The Cambridge Green Infrastructure Strategy provides a nationwide framework for delivering or improving GI in Cambridgeshire by 2031. Strategies also show how GI contributes to "*reversing the decline in biodiversity, mitigating and adapting to climate change, promoting sustainable growth and economic development, and supporting healthy living and well-being*".(URL 2020). Proe is already an impressive guide with successful results.

European Union (EU)

The issue of GI has begun to attract attention in the European Union since 2011. This interest focuses on "reducing biodiversity loss and promoting sustainable resource use." Additionally, GI has been recognized as "embodying the spatial representation of sustainability." In this context, it was decided to revitalize the landscape value to improve GI. In this context, declarations and reports have been published and projects have been developed (Fesel, 2020).

European Commission; It sees GI as "a successfully tested tool to deliver ecological, economic and social benefits through natural solutions" (European Commission, 2023). The Commission, Cohesion Fund and European Regional Development Fund (ERDF) define GI applications as a priority investment area (Tuna, 2021).

The GI system is encouraged in all EU policies to restore nature and increase biodiversity. GI is a network of natural and semi-natural areas that provide a wide range of ecosystem services. It is a strategic plan (European Commission, 2023).

In the declaration published by the European Commission in 2013, the principles regarding GI were expressed as "*GI is important for the protection and development of nature, natural*

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

processes and the many benefits that individuals derive from nature" and "It should be integrated into spatial and regional development" (Tuna, 2021).

The EU's Green Infrastructure Strategy calls for GI to be an integral part of regional development. The Europe 2020 Growth Strategy points out that GI can make a significant contribution to many areas. The Biodiversity Strategy aims to ensure the maintenance and development of ecosystems and their services by creating GI and repairing at least 15% of the damaged ecosystem by 2020 (Dige, 2015).

GI has also been recognized in different areas of EU policies, especially within the Seventh Environmental Action Program (7EAP), Regional Policy 2014–2020, Water Framework Directive, Nitrates Directive, Floods Directive and the EU Strategy on Adaptation to Climate Change (Dige, 2015).

As a result, there are impressive policies regarding GI in the EU. The EU's GI policies have the goal of promoting the use of clean energy sources, reducing emissions and increasing resource efficiency. Establishing high-level directives, financing and incentives at EU, national and local levels. Incentives are given such as tax deductions, project grants and loans. There are very comprehensive directives on this subject and financing opportunities are provided. The main EU financial incentives for GI projects are provided by the European Structural and Investment Funds (ESIF), which constitute a significant part of the EU budget, allocated to strengthen the economic-social cohesion of member countries. The Cohesion Fund is another source of projects. The European Investment Bank (EIB) also supports the process by providing loans (Zakrisson, 2023).

There are impressive examples and projects of GI projects in EU member countries. Hamburg (Germany) is one of the leading cities in the EU in GI policies. Hamburg has a comprehensive green roof strategy. The goal is to create roof gardens and green the roofs in at least 70% of new buildings. The Hamburg Ministry of Environment, Climate, Energy and Agriculture has supported the project with 3.5 million Euros until 2024. In addition, various financial incentives and supports have been offered to the residents and businesses of the city of Hamburg. Within the scope of the project, GI policies have proven to be successful in Hamburg. Policies have demonstrated how cities can simultaneously use GI initiatives to achieve environmental and financial goals. Austria is another important country regarding GI projects. Many municipalities in Austria have focused on afforestation to tackle climate challenges. At the same time, they have chosen to protect against heavy rainwater events and reduce energy consumption with green roof and green wall technologies. Today, the green roof and green wall industry has turned into a big industry. Additionally, 20 research institutes are working on innovative solutions for smart cities and urban GI projects. The green roof association Grün-Statt-Grau is very influential in making Austria greener. Additionally, Vienna has adopted a proactive approach to GI. Another city that offers impressive examples of GI is Amsterdam (Netherlands). Its goal is to be carbon neutral by 2050. He considers GI an important tool for this goal. The government offers subsidies for green roofs, green facades, rainwater harvesting systems (Zakrisson, 2023).

Chinese

The central government has launched a series of campaigns, policies and regulations to reflect environmental concerns in its cities, which have become known for their entrepreneurial nature

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

in the post-period From the 1990s to the present (Xu and Chung, 2014). The “green is gold” rhetoric of Xi Jinping, China's top leader since 2012, has supported GI development in China today. However, China's GI theory is relatively weak and public participation/awareness is relatively low (Zhou, et al., 2022).

China's latest national urbanization plan, the National New Type Urbanization Plan (2014–2020) (NNUP), has highlighted environmentally friendly urbanization. This situation has increased the pressure of green urbanism and urban green projects have increased. Especially the greenway projects with a GI component have increased. Greenway projects first came to the fore in 2010 in the Pearl River Delta (PRD) and were widely adopted thereafter. Greenways projects have been launched in 31 provinces under the leadership of the government (Zhang et al., 2020).

In the process, it has moved beyond the traditional approach to nature-based holistic approaches. As the key to this approach, the Sponge City Program (2013) was initiated. The program is guided by the Ministry of Housing and Urban-Rural Development, the Ministry of Finance and the Ministry of Water Resources. Sponge City Programme; It has GI such as absorbent roads and permeable pavements, rain gardens, parks and wetlands, and built environment measures such as green roofs and rainwater reuse facilities. Between 2015 and 2017, the national government invested in 16 pilot sponge cities (US\$3 billion). It is aimed that 20% of each pilot city land will be built according to sponge city standards by 2020 and 80% by 2030 (Oates, et al., 2020).

In the World Bank Report; It has been stated that «climate change poses a serious threat to China, especially in densely populated and economically critical sea-level coastal cities». It has been emphasized that uncontrolled climate change could reduce China's economic output by 0.5% to 2.3% in 2030. It has been stated that China needs up to 17 trillion dollars of additional investment in GI and technology in the energy and transportation sectors in order to reach net zero emissions by 2060 (Shalal, 2022).

Today, the important component of the transition to urban sustainability in China is seen as the planning and development of forms of GI (Shi & Qin, 2018).

Japan

Japan became the symbol of environmental pollution and ecological problems with rapid industrialization in the 1950s and 1960s. He cleaned up his actions and his environment in the 1980s and 1990s, but devoted all his attention to the energy problem. This was the way he could develop, become stronger and revive his industry. However, it had a deep spiritual, artistic and cultural connection with nature and land, and this relationship made its stance on the economic development-nature-environment relationship different from other countries (Holroyd, 2018). This stance has been important in giving open green spaces a different place in urban planning in Japan.

Japan has examples of GI implementation since the 1960s. However, in most of them, the full potential of the GI concept has not been realized. There is still a lack of a systematic approach. Tokyo, for example, has had dense green space since 1960. However, there is no connection between green areas. But now, the Tokyo Metropolitan Planning Department recognizes the importance of the planning hierarchy, from the national level to the broad regional, prefectural

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

and neighborhood, city, town and village levels. It attempts to coordinate green space planning at these levels. It also plans to protect the coastal vegetation and corridor (Kato, 2011).

In the late 1960s, Kohoku New Town in Yokohama city was the first example of GI. It realized a connected, integrated network of open spaces, including various open spaces, pedestrian paths and water. The features of Kohoku New Town are as follows (Kato, 2011):

- He valued open spaces equally over traditional infrastructure
- Used geographical indications to shape development and conservation
- Developed a layered, rather than hierarchical, system of connected parks and pedestrian paths

On this day, the Japanese government recognizes GI in the national spatial strategy. In Japan, GI is increasingly recognized as a new concept that combines various fields such as environment, urban development, and disaster prevention/mitigation (Kida 2017). GI aims to benefit from the various functions of the natural environment, improve local attractiveness and living environment, and prevent/mitigate disasters (National Spatial Strategy, 2015). In addition, Japan has created GI technology on an urban scale, based on natural, cultural, social and economic situations specific to the country. In this context, three more elements were added to EPA's 11 GI elements. These; green parks, wall greenery, lawn square ground (Kida, 2017).

With the beginning of the scientific and technological revolution in the 21st century, the Japanese government and various prefectures across the country have believed that invention-innovation-transformation will be the most effective means of preventing environmental problems. This belief combined science and technology with the imperatives of the age of environmentalism. Today, demands for environmental adaptation, technological transformation opportunities and economic development imperatives in the fight against climate change have turned into a comprehensive national movement. In particular, the fact that climate change threatens economic and ecological well-being requires green strategies that will reduce emissions and promote economic growth (Holroyd, 2018). At this point, Japan make successful progress. Tokyo, the world's largest and most successful megacity, is a global leader in urban design, rapid transportation and environmental measures (Holroyd, 2018). In Tokyo, open green areas and GI, which ensures the systematic planning and design of these areas, are protected and developed because they provide sustainable living (Wybe, 2014).

There are municipalities in Japan that implement GI to combat heat islands. However, managers state that the desired success has not been achieved. GI Tokyo Biodiversity Strategy for 2030 has also been announced in terms of combating climate change and protecting biodiversity. The strategy highlights the heat island mitigation effects of green spaces, roofs and walls and is important in improving GI. Today, The Tokyo Metropolitan Research Institute for Environmental Protection is investigating the effects of improving the GI thermal environment and they plan to use the findings for future environmental management measures (Giseburt, 2023). In this context, the Japanese Government has set targets to achieve zero greenhouse gas emissions by 2050 and promote the digital transformation of the Japanese economy. Some tax incentives have been introduced to achieve these goals. These incentives were introduced as part of the broader Industrial Competitiveness Enhancement Act. Additionally, on March 26, 2021, Japan's 2021 Tax Reform Bill (the Bill) was signed into law. The law provided tax incentives for Carbon Neutral and Digital Transformation investments. On December 22, 2022,

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

the government announced the Green Transformation (GX) policy. The policy defines regulatory, financing and technology development priorities for various industrial sectors with a focus on green transformation (EY, 2023). In addition, the Japanese government aims to implement "carbon pricing", which combines "carbon tax" with voluntary "emission trading", starting from 2028 (IM, 2023). These innovations focused on climate change have increased the importance of GI plans in the country. Moreover, the increasing river flood risk in recent years has focused the attention of managers and ecologists in Japan on flood risk management using GI (Ishiyama et al, 2023).

India

More than 30% of India's population lives in urban areas (according to the 2011 Census). Industrialization accelerated migration to cities, and cities developed without planning. Urbanization has caused land scarcity, environmental problems and unfair distribution of urban opportunities. Today, climate change has added new ones to these problems. The increase in extreme weather events such as droughts, hurricanes, forest fires, heat waves and floods is attributed to climate change. Overpopulation, lack of green financing, inappropriate policies and low awareness are the main obstacles to achieving the "Green City" (Chakraborty, 2023).

In India, GI was used for the first time within the scope of environmental policies in the Fourth Five Year Plan (1964-69). With the establishment of the Ministry of Environment in 1980, air-water pollution and protection of natural resources. etc. issues have been brought to the agenda more frequently. In 2014, the Ministry was updated as the Ministry of Environment, Forestry and Climate Change. In 2008, it prepared the National Action Plan on Climate Change (NAPCC) in response to the United Nations (UN) Framework Convention on Climate Change and the UN's Green Economy Initiative. NAPCC has developed Smart Cities Mission and Atal Mission for Rejuvenation and Urban Transformation (AMRUT) projects involving blue and GI. The Smart Cities project focuses on water supply, protection of open spaces, and improvement of quality of life. AMRUT aims to improve water supply, sanitation and green areas (Mankikar & Driver, 2021). With these developments in Indian history, the use of GI has increased. Especially the fight against climate change has taken GI to a different point.

The concept of GI is often used together with "blue infrastructure" in India. It is defined by its involvement in policies at the central, state and sub-regional level. For example, Delhi Development Authority GI refers to trees, lawns, hedges, parks, fields and forests. Blue infrastructure refers to water resources (rivers, lakes, canals, wetlands, floodplains, water treatment facilities). He defines blue-green infrastructure as urban planning where water and land holistically provide environmental and social benefits (IAS PARLIAMENT, 2023).

Important initiatives/projects under the name Blue-Green Master Plan on GI in India. The first of these were prepared for Delhi, Bhopal, Madurai and Bengaluru. Delhi is one of the first cities to include blue-green policies in its 2041 master plan. The main objective of the policy is to ensure synchronized and interdependent planning of water bodies and green spaces. Public participation guides the process (Rajput, 2020). Bhopal of Madhya Pradesh is a city of lakes. It is one of the 100 smart city projects. By protecting and developing green areas on the basis of GI, a sustainable city with a high quality of life is aimed (Bhopal Smart City Development Corporation, 2016). Madurai Municipal Corporation has come up with a blue-green action plan to address water challenges, climate adaptation and flood mitigation faced by the city and the Vaigai Basin. The plan was developed with a participatory approach (Madhan Kumar &

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

Vasimalai, 2016). A blue-green action plan has been prepared in Bengaluru to ensure resource security, climate resilience, transition to a low-carbon economy and ecosystem protection (Mankikar & Driver, 2021). In India, GI gains different values depending on the status of the cities (Table 1).

Table 1. Values of GI in Indian Cities (Mell, 2015)

Value	Activity/Process	Location
Ecological	Trees (water, climate and pollution);	Chennai;
	Water (supply, regulation, pollution);	Bengaluru;
	Managed green space Generic green space (regulating, pollution, habit, biodiversity);	Mumbai; New Delhi;
	Generic green space (regulating, pollution, habit, biodiversity)	Karnataka; Kochi
Economic	Tree commerce; Retail/property values;	New Delhi;
	Consumer/employee well-being; Health costs	Kolkata; Mumbai;
Social	Communal engagement/cohesion;	Chandigarh;
	Sports and recreation; Health and well-being (mental and physical);	Gandhinagar; Bhubaneswar;
	Housing	Kolkata

Iran

Iran has hardly developed GI components in its planning and urban development programs (Sarihi, 2015).

The main GI in Iran are parks and gardens that serve general functions such as recreational space for the community. The main reason why green spaces in Iran's contemporary cities are poor at micro and macro scales is that the dominant approach to green space development focuses only on green space per capita. In other words, there is an attitude that focuses on quantity. Components of the green network in Iran's contemporary cities lack connectivity with other functional city layers and structures. This situation hinders the environmental, social and economic benefits of green areas (Saboonchi et al., 2018).

Environmental quality is deteriorating in many cities in Iran. Tehran, which has 40% of the country's industry, is one of the most polluted cities in the world. According to the World Bank's latest report in 2018, Tehran reached 10 PM in air pollution. It is among the 62 most polluted cities in the world. In Tehran, 4000 to 5000 people die every year due to air pollution (Boostani and Sadeghiha, 2022). In fact, for the last 20 years in Tehran, the development of new green areas and the improvement of existing green areas is a strategy to reduce air pollution and increase the level of public health (Ahmadi et al, 2017). However, the implementation of the strategy is insufficient. Because the connectivity of green areas in Tehran is low, especially in the central city matrix, there is almost no connectivity. The connection with natural areas is gradually decreasing, which causes environmental problems to increase and the quality of life of the city to decrease (Yazdanpanah et al., 2015).

The division of society into social statuses (high, medium, low) in Iran prevents equal access to public green spaces. As in the case of Tabriz, the public can access green areas at the level

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

recommended by the government. The areas with high social status have the best park, and accessibility. Social discrimination is reflected in the approach to planning open green spaces and negatively affects connectivity (Breuste & Rahimi, 2015).

Today, Iran is experiencing alarming levels of floods, storms, droughts, subsidence and forest fires due to the effects of climate change. While the number of disasters was below 100 between 1900 and 1980, this figure was 400 between 2000 and 2019. This situation is attributed to high carbon emissions and climate change (Tourani et al., 2022). Today, the world is criticizing Iran's process of combating climate change. Iran has not signed the Paris Agreement, which is a turning point in the fight against climate change. The embargo and economic impasse negatively affect its fight against climate change and environmental problems. America has even blocked access to the funds allocated to Iran by the Global Environment Facility (GEF) for environmental problems. Iran's discourse on this issue is clear: "You cannot expect a country with serious socioeconomic and political problems to focus on climate change." Under current circumstances, Iran maintains its composure towards the transition to a green economy. In short, Iran clearly states that it cannot combat the threat of climate change in its current situation (Mahoozi, 2020). This situation prevents the development of GI, which is seen as the most powerful tool in combating and adapting to climate change, in Iran.

In scientific studies that do not slow down despite Iran's economic and political situation, GI is presented as a solution in the fight against environmental problems, ecological sustainability, equal access to public spaces, and new urban planning approaches (Breuste and Rahimi, 2015; Ahmadi et al., 2017; Ramyar et al., 2019; Bostani and Sadeghiha, 2022, Rahimi and Breuste, 2023). However, ecology-based planning studies on an urban scale in Iran are a new field. Financial resources are lacking in this sense (Ramyar et al., 2019).

Türkiye

According to the first census carried out in Türkiye in 1927, 75.8% of the population lived in towns and villages and 24.2% lived in provincial and district centers, but after 1950 the population began to gather in urban areas. According to the 2021 results announced by the Turkish Statistical Institute (TUIK), 93.2% of the population lives in provincial and district centers (Ministry of Environment, Urbanization and Climate Change, 2023a). This rapid, unplanned and un-ecological urbanization process has been the architect of cities where the quality of life is low, environmental problems are increasing, natural areas and biodiversity cannot be protected, etc.

The 1972 United Nations Stockholm Human Environment Conference had a great impact on addressing the environmental issue at the policy and management level in Türkiye. This effect has also led to the adoption of many international agreements. In this context, for the first time in Türkiye, III. The environmental issue was emphasized in the Five-Year Development Plan (1973-1977). Afterwards, the environmental issue was increasingly addressed in the legal and administrative structure. This situation has also been addressed in the urbanization process.

The Zoning Law, Zoning plans and relevant regulations have come into force for the planned and rational progress of urbanization in Türkiye. However, it was insufficient to slow down the process and prevent problems. This situation is seen in existing city examples. In order to solve the problems experienced in recent years, the Spatial Plans Construction Regulation (SPCR) dated 2014, which includes the latest updates on the implementation of the Zoning Law, was

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

put into practice. The regulation has comprehensive discourses aimed at producing solutions for structural and natural areas. For this reason, it is the key legislation in Türkiye's urbanization process. The most important legal discourse on the planning, design, implementation and protection of open green areas in Türkiye is SPCR. There is no GI concept in the regulation because the concept is new for the legislation in Türkiye. When the regulation is examined based on the open green area system, it is inadequate in many aspects, especially conceptual perception, planning principles and ecological approaches. Because open and green areas are seen as only social infrastructure areas (open and closed sports facilities, parks, playgrounds, playgrounds, squares, recreation areas, etc.). The planning, design and projecting of open green areas and the principles and objectives in this process are not given in the regulation. Beyond the holistic approach, there is a fragmented approach for coastal, rural, road and urban areas. It also focuses on a quantitative perspective where green areas per capita are given. This attitude is an indication that the perception of GI system approaches is not included in the Regulation (Karadağ et al. 2019; Demiroğlu et al., 2019; Karadağ et al. 2020).

Open green area plans are prepared within the scope of Development Plans. Zoning plans are prepared according to Basin/Provincial Environmental Plan. The concept of environment is effective in the Basin/Provincial Environmental Plan. However, it is insufficient for green space planning at the city level and lower scale. For this reason, the planning hierarchy cannot go beyond advice on GI. The most effective institutions in open and green space planning and design on a local scale are municipalities. Urban open green area projects are not produced in municipalities. There are no open green area projects at the development plan scale (1/5000, 1/1000) or urban parks and landscape projects for some parks can be accessed in a fragmented manner. However, there are no holistically prepared urban open and green area projects at the city scale. The process is carried out by the Municipalities' Directorate of Planning and Urbanization, Directorate of Technical Affairs, and Directorate of Parks and Gardens. There is no mechanism that provides participation in the project design process (Demiroğlu, et al., 2019; Karadağ et al. 2019). The Urbanization Council held in 2009, within the scope of solving some of these problems, enabled the preparation of the Integrated Urban Development Strategy and Action Plan Preparation Project for Urban Development. The project's final report was declared as Integrated Urban Development Strategy and Action Plan-KENTGES (2010–2023) on March 3, 2010. KENTGES is a road map for central and local governments on urbanization and zoning issues (Ministry of Environment, Urbanization and Climate Change, 2023b). The report includes strategies for planning open and green space systems and protecting existing areas. In this sense, it is very important for Municipalities. In addition, the GI Guide for Municipalities was prepared in 2021 under the leadership of the Urban Research Institute. The purpose of the guide is to guide local governments in terms of theoretical level and implementation steps (19.09.2023) to ensure that they handle all spatial planning and implementation processes within the understanding of GI (Karadeniz & Taşkın, 2021). The recommendations in the aforementioned project and guide are key for all participants in the GI management-planning-design process. However, there is a problem of technical personnel with competent and sufficient knowledge in putting it into practice. In addition, the process may be affected by urban-scale management policies and the power of political authorities (Demiroğlu, et al., 2019; Karadağ et al., 2019).

Today, there are no incentives (grants, loans, funds) in developed countries regarding GI in Türkiye. However, there are strong recommendations on this issue and projects on the subject

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

are given priority. For example, Türkiye Ilbank and the World Bank (WB) Sustainable Cities Project was carried out (Ilbank, 2019). In the USD 784 million Sustainable Cities Project, a series of studies are carried out together with municipalities to support climate change mitigation and adaptation, such as rainwater, emergency response, solid waste disposal, renewable energy use, energy efficiency and sustainable transportation in urban planning. The project also seeks ways to increase the resilience of cities. In addition, the Government, with support from the World Bank, has conducted three city-wide disaster and climate risk assessments to identify key infrastructure and housing that require urban resilience investments, such as housing retrofitting, drainage improvements, public space and social infrastructure (World Bank, 2023). All these projects are important developments in terms of the protection, development and planning of GI systems.

2. MATERIALS and METHODS

The study was conducted on the example of America, England, EU, Japan, China, India, Iran and Türkiye. GI systems in countries were examined based on institutional reports and projects, regulatory documents and relevant literature. The review was conducted based on institutional structuring, legal structuring, incentive systems, reflection on practice/projects and scale perception regarding GI. The findings were interpreted within the scope of the GI approach of the countries.

3. FINDINGS and DISCUSSION

Space is shaped and characterized by differences in natural, social, cultural and economic structure and turns into a "place". For this reason, it differs from country to country, from region to region, and from urban to urban. In addition, each urban's acceptance of new approaches or their post-acceptance adaptation is different for this reason. A good example at this point is that the GI system has different perceptions in countries, despite the proven benefits it provides to the city.

The historical background is very effective in countries' GI practices. The USA and the UK were early in implementing the GI system, as they had "applications of open green areas, green roads, new urbanism trends in the urban planning process" since the 19th century. They demonstrate effective examples in every field such as planning, implementation, design, policy, etc. European countries have also adapted quickly to these GI systems. However, in other countries, the process progresses slowly. Today, GI systems are not reflected in the management in some countries, in the legislation in some countries, and practice in some countries. It is a concept used in the scientific world in some countries.

Scientists in the field of spatial planning see GI systems, which are a nature-based or nature-resolution approach, as a powerful planning tool, focusing on combating/adapting against climate change, rainwater management, urban biodiversity protection, and urban disaster management. However, each country's practice and discourse regarding GI is different. Today, developed countries, guided by science, have transferred the GI system to the urban planning process with strong laws and institutional systems (for example USA, UK, EU countries). In countries that are affected by scientific data but cannot put it into practice due to social-cultural-economic conditions, GI is a government recommendation (for example Türkiye). Today, in most countries, GI is the subject of scientific research as a nature-based solution to many problems

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

(for example Iran). In short, the difference in the reflection of the GI system in practice is parallel to the development level of the countries and their use of science as a guide.

The perception of scale regarding GI systems varies from country to country. This change in perception also affects institutional structuring and legislation. For example, the USA, the UK and EU countries produce structures and policies that address GI at the basin and urban scale. In countries such as China, Japan, India, Türkiye and Iran, the focus is on the functioning of GI at the urban scale. This may cause GI systems to have different applications in countries.

GI systems are solutions with high initial costs. Therefore, it requires strong incentives (credits, tax deductions, project grants, expedited permits, etc.). Incentives are primarily dependent on the country accepting the GI system as a solution. Then, the economic situation of the country manages the process of promoting environmental/nature-oriented policies. America, the UK, and EU countries have strong and impressive GI incentive programs. Incentives are given to institutions, the private sector and the public. In countries such as Japan, where GI-related practices are gaining importance day by day, incentive programs are expanding. In some countries such as China and India, grants are given to projects in plot areas. In some countries, support is given to only scientific projects related to GI. In short, projects/applications related to GI systems have different incentives from country to country.

Developments regarding GI systems and the social, cultural, economic and political situations of countries are very important. Today, Iran states that it cannot handle studies on GI systems due to its current economic and political situation. The USA, on the other hand, prevents Iran from accessing environmental funds allocated by GEF. In this context, GI is an example of how countries still conduct policies based on "environment/nature".

4. CONCLUSION and RECOMMENDATIONS

The green infrastructure system is the "key component" recommended by today's scientists within the scope of resilient and sustainable urban planning. When the scientific literature is examined, some philosophical discourses can be made regarding green infrastructure. For example, green infrastructure is based on the concept of planning on the basis of the natural processes/system that originates in the city. The green infrastructure system includes the acceptance that the city cannot be planned only in line with human needs, desires and dreams. Green infrastructure adopts the principle that "the city is based on a resource/essence that is too sensitive to be a demonstration of technology." Green infrastructure adopts the motto of planning the natural and man-made, again under the guidance of nature/creation. Today, these discourses are spreading to countries that conduct scientific studies on green infrastructure.

Countries' use of scientific information varies according to their socio-economic, political and cultural structures and their attitudes towards using information as a guide. Even if human life and the common future of the world are in question, the attitude toward using knowledge as a guide does not change easily. However, attitudes can be directed through international policies and collaborations. For these reasons, the world is the scene of different countries, cities, etc., in the same time period / in the light of scientific data. The implementation of green infrastructure systems is a clear example of this situation. Every country creates its cities according to its reality, despite science.

Countries that use scientific data as a guide shape their realities in the light of information. For example, when the countries where green infrastructure systems are implemented are examined,

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

some points attract attention. These are (i) GI is projected at different scales (basin, regional, local) (ii) Planning-design requires a participatory approach (public, private institution, public, etc.) (iii) It is guided by laws (iv) It is supported by political discourses (v) It has incentive programs and is supported (vi) It is implemented with pilot projects (vii) Projects are produced by GI experts (landscape architects) and competent technical staff (viii) It has application guides for local governments (ix) Its contributions are investigated through scientific research (x) Gray infrastructure It is recommended to evaluate holistically with blue infrastructure. This situation also causes countries to improve each other in the light of science. It provides collaboration. Collaborations on nature/environment create a system whose impact is becoming stronger.

As a result, green infrastructure systems are an approach that makes significant contributions to the fight-adaptation process against global warming, from urban environmental issues. This impact on cities is a very important force for the common future of the world. Urban green infrastructure systems in all countries in the light of scientific data and material and spiritual global cooperation; It should be included in the urban planning process "at national-regional-local scales, by expert groups, with a participatory approach, technological power, impressive legal infrastructure, long-medium-short term policies, encouraging economic supports, deterrent sanctions". In addition, detailed planning and design guides for local governments should be created and the process should start with pilot applications. Because cities are the most critical areas that determine the present and the world of the future.

ABSTRACT

Historical areas are memory spaces that transfer the characteristics of the past to the present. Due to the rising population and urbanization in cities, the accessibility of historical city centers can be negatively affected. The protection and development of the spatial characteristics of historical city centers is important. This research aims to analyze the intelligibility values reflecting the accessibility and spatial characteristics of the streets in the Çankırı Urban Sites. In the research, spatial integration maps were analyzed by using the space syntax method. Visibility graph analysis was utilized on the street texture to examine the intelligibility of the historical city center. As a result, it has been revealed that the streets with socio-cultural uses such as traditional architectural patterns, trade areas, and community centers have a high integration value and are effective in the spatial configuration.

Keywords: Accessibility, Historical Site, Space Syntax, Spatial Analysis, Street Layout.

1. INTRODUCTION

Historical areas contribute to cultural and social life and are shaped by human behavior. Due to rising urbanization in the world, urban spaces are changing in cities. The increase in population in cities causes the morphological structure of the urban areas to change. Understanding the urban texture in the historical city center is important for the development of the city. The correct perception of the cultural, social, and economic layers in historic city centers will facilitate the correct perception of urban identity and the implementation of appropriate projects (Kepenek et al., 2015). The voids in the historical environment are of great importance as open spaces that add meaning to the urban whole with the features they contain (Özkaraca & Halaç, 2021). The gathering places, directions, and movement directions of human communities living in a settlement are determined according to the system formed by the geometry of that settlement (Alemdar & Özbek, 2021). In this context, the spatial characteristics of the street texture that forms the mathematical infrastructure of historical city centers should be analyzed.

A systematic analysis of the spatial characteristics of the building should be made by developing a mathematical model without damaging the traditional values of the historical centers of the planning process (Has, 2022). Space configuration includes sequence in the transition between spaces, succession, change of movement route in transition, presence of alternative transitions, and intersection of transition routes in different directions (Erman, 2017). In this context, the street network, which determines the movement routes in the spatial configuration, has an effective role in the study of cities. According to Hillier and Hanson (1984), spatial configuration features of buildings and settlements can be examined with the space syntax method. The space syntax method, which examines space configurations, is used at many scales, from the building scale to the city scale, in research on spatial features in urban public

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

spaces. Space syntax methodology provides tools to analyze the linguistic properties of space, namely configuration, visibility and accessibility, and their functional relationships with the physical, social and spiritual environment (Turner, 2001). This method allows us to analyze open spaces other than architectural structures in historical areas. On the other hand, D'Autilia and Spada (2018) emphasize that spatial organization should be perceived as three-dimensional, not two-dimensional. Therefore, it is important to add the third dimension with visibility analysis, which provides the perception of space in urban areas.

The Urban Site Area located in the city center of Çankırı, which is the case study in research, is a traditional settlement area with its oldest neighborhoods and cultural values. Çankırı is one of the small cities of Türkiye, gives the city its identity with its historical heritage from past to present. The city of Çankırı has a very old history, with human traces dating back to the Paleolithic Period (Çankırı Kültür & Turizm Bakanlığı, 2023). The city, which is home to many civilizations, has preserved historical and cultural values with its registered architectural structures.

The city's original architecture such as monuments, mosques, madrasas reflect the historical texture. The original architecture of the city reflects the historical texture. It is necessary to improve physical accessibility in order to protect the historical city center of Çankırı, where many architectural structures are located, and to increase its functionality without harming its texture. Creating an urban center that keeps the historical texture alive is important in terms of sustainability. The aim of the study is to reveal the integration of the streets in the historical city center and to improve their spatial characteristics. In the study, the places where pedestrian mobility is the majority in the historical city center of Çankırı were analyzed. As a result, it has been determined where cognitive experiences can be developed in the historical city center. The relationship between the spatial organization of the street network and integration values in the historical area was examined. The relationship between Çankırı Urban Sit Area and the city center was examined through the street network that forms the city morphology. The accessibility of the streets in Çankırı historical city center was evaluated using the space syntax method. The study is important to evaluate the results of pedestrian movements in the streets through mathematical analysis and to reveal and improve the places where disconnected relations occur in the historical area. The study also provides ideas to public authorities, urban planners, designers, architects and landscape architects on the development of street texture in the protection of the historical environment and the implementation of this example in small cities.

This study consists of three stages. In the first stage, the values related to the street texture created by spatial integration values were examined. In this context, data from the study area were collected and high or low integration areas of the street texture were revealed using the space syntax method. In the second stage, visibility graph analysis (VGA) was applied to identify perceptible areas in the street texture. In the conclusion part, in line with all the data obtained, axes to increase the usage areas of people in the historical area were evaluated.

2. MATERIAL and METHOD

2.1 Material

Çankırı province is in the northeast of Ankara, the capital of Türkiye, was chosen as the study area. The coordinates where the Çankırı province is located are between 40° 16' N and 41° 04'

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

N and 32° 34' E and 34° 08' E. The historical area located in the center of Çankırı province and the surrounding metropolitan area constitutes the main material of the study. An analyzes was made on the current map obtained from Çankırı Belediyesi (2022). The study case was analyzed through fieldwork, observation, satellite photographs, and other data regarding the location. The study area was chosen because it traces back to different periods in the past, is one of the intensively used and highly accessible areas of the city and reflects the original traditional architecture of the city. DepthmapX 0.80 software, literature research, field analyzes and current maps for the application of the space syntax method in the study are other materials of the study. The geographical location of the study area is given in Figure 1.

Figure 1. The geographical location of the study area

2.2. Method

The space syntax method was used in the study. Spatial syntax theory is a graph-based theory developed by Hillier and Hanson (1984). Spatial Syntax is a set of techniques supported by theoretical approaches, used to define the spatial models and intra-building space organization of built environments, regions, cities, and building groups at different scales and to examine their interactions with the social structure (Gündoğdu, 2014). Unlike computer-generated designs, the spatial sequence method is also effective in the formation of a spatial structure that acts according to social data by drawing some conclusions based on observations and analyzes. (Özkan Özbek, 2007). Therefore, space syntax helps to understand the user experience and analyze the physical structure of space. With the space syntax method, axes are created on open spaces and spaces are classified according to the places where people are most frequently present in these areas and the places where people are less likely to be present.

Çankırı city street network data was collected in order to perform space syntax analysis in the study area. The intelligibility of space refers to the relationship between its integration and connectivity values (Günaydın & Yücekaya, 2020). In this context, two different values were considered to evaluate the data collected and to examine the street network features. These are connection and integration values. Hillier (2007) explains these values as follows:

1. Connectivity is taken as an indicator to explore the degree of connectivity of a given space with other spaces.
2. Integration relates to the integration of a line into all other lines of the axis map.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

In the first stage of the study, integration maps were obtained through spatial analysis. Spatial integration value was calculated based on the axis maps produced over the street network. The integration value is a number obtained to reach from one axis to another axis and provides information about the accessibility level. Integrated spaces have the potential to bring together all the people who live in a place or are there for any reason (Has, 2022).

In the second phase of the study, Visibility Graph Analysis (VGA) was used for the visibility relationship within the area. VGA is often used to study the visibility relationship between spaces at a semi-urban scale (Turner, 2001). This analysis measures the perceptibility of the public space by examining the area between the street network and the buildings. According to Turner (2003), VGA provides us to understand how people move or interact in visible space. It evaluates how visible urban open spaces are in an area by performing a three-dimensional visibility test. In this context, visibility graph analysis was performed on the gridal system according to the human scale on the street texture of the study area. In this context, visibility graph analysis was performed on the gridal system according to the human scale on the street texture of the study area.

In the last stage of the study, the common results of all the data were evaluated and the streets with high values of movement and perceptible areas were revealed. A general synthesis and evaluation of the data obtained by the two methods used together with the analysis of the field study with the space syntax and wayfinding methods of Çankırı Urban Site Area was made.

3. RESULTS

3.1 Space Syntax Analysis

The historical center located in Çankırı city center is one of the oldest settlements. The study area, which includes the city's protected area, provides different spatial experiences to users. Analyzing the route formed by the street network becomes important in terms of understanding the experiences in the area with its architectural structures. The relationship between buildings and the street network can directly affect people's experiences. With the space syntax method, the spatial configuration of the space along with the user experience was analyzed. The street pattern in the Çankırı Urban Site Area is given in 2a, the axial map created by the topological analysis of the space arrangement based on axial lines is given in Figure 2b, and the integration map is given in Figure 2c.

Figure 2 a. Street pattern b. Axial map c. Integration map

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

It is seen that the street network formed by the traditional housing texture within the Çankırı Historical Site is irregular. The urban renovation practices are carried out within the area within the framework of the conservation plan. There are narrow roads and dead-end streets in most places in the area. Integration and connectivity maps for the area are given in Figure 3a and Figure 3b.

Figure 3. a. Connectivity map b. Integration map

The integration value of the area increases in the center and at the intersection of axes. On the other hand, the axes that provide the longest and uninterrupted transportation within the area have high accessibility. Uzunyel Street, Manifaturacılar Street and Vali Ayhan Çevik Street in Çankırı Urban Site Area have the highest integration value. These axes form the main spine of the area and the accessibility level of the streets connected to these axes is relatively high. Streets with high integration value are suitable for developing tourism and bringing people together. The highest integration value in the area is 2.84 and the lowest integration value is 0.72. It is seen that Uzunyel Street has the highest value in the area with an integration value of 4.72. Maximum, minimum and average values for integration and connection maps are given in Table 1.

Table 1. Maximum, minimum and average values of integration and connectivity maps

Values	Minimum	Mean	Maximum	Std. deviation
connectivity	1	8.60377	42	6.74072
integration	0.726546	1.62715	2.84202	0.416166

The correlation graph of connection and integration values, which express the intelligibility of the study area is seen in Figure 4. In general, the intelligibility value given as R^2 is evaluated in three ways: weak, good or strong, R^2 values between 0-0.5 are positioned as weak spatial identifiability, and R^2 locates at 0.5-0.7 which indicates that spatial identifiability is good (Lin et al., 2007). Accordingly, it turns out that the relationship between integration and connection values in the area is good with a value of 0.649.

September 14-15, 2023, Naples, Italy

Figure 4. Correlation graph for connection and integration values

Although the accessibility value of the area seems to be high in the center, this value is gradually decreasing in the whole area. Therefore, it becomes clear that the accessibility degree of the area can be improved. Generally, it is seen that the historical region has a complex street texture. Visibility graph analysis was examined to measure the level of perceptibility.

3.2 Visibility Graph Analysis

Streets with historical and cultural characteristics are areas that provide a connection between the city and sociality. When examining historical areas, in addition to spatial organization, the perceptibility of the place should also be taken into account. In this context, visibility graph analysis was applied in the research for the perceptibility status within the street network. Within the scope of VGA model analysis, isovist areas are extracted through pedestrian flow simulation. An isovist is a set of all points in space visible from a given vantage point and relative to a perimeter, and the shape and size of the isovist are liable to vary with location (Benedict, 1979). The visibility graph analysis of the streets in the study area is given in Figure 5.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 5. Visibility graph analysis of streets in the study area

As a result of the visibility graph analysis, images of the streets with high integration values in the historical area are given in Figure 6.

Figure 6. Streets with high accessibility values in the study area

Uzunyol and Vali Ayhan Çevik Street, which have a high integration value in the area, are the axes on which the traditional housing texture is shaped. The architectural structures located on these axes have been effective in creating an uninterrupted line of the street texture and at the same time increasing the integration value. Manifaturacılar, Bakırcılar and Elif Street are the axes where commercial use is concentrated in the area. It was seen that the commercial areas located on these streets are another factor in the configuration of the streets and the high value of spatial integration. İmaret and Büyük Cami Streets, which are among the streets where mosques function as gathering areas in the historical region, are located, and also have a high integration value. The rise of common-use areas in these axes has increased the integration value.

4. RESULT

In recent years, due to the change in cities, has caused forms in the social-cultural and physical structures of city centers. Historical areas in city centers are places that may be negatively affected by this change. In this context, there is a need to develop studies aimed at examining the urban texture.

With its registered urban sit area located within the city of Çankırı, it is one of the sample areas that add social and cultural values to the city. To protect this area, the street layout that forms its physical morphology must be analyzed. In this context, the spatial configuration of the streets in the historical region was analyzed in the study. In the analysis, it was revealed that the results of the connection and integration maps that provide the analysis of the intelligibility of the streets are good. Streets with high perceptibility create potential for the development of tourism routes. Mansouri and Ujang (2017) used the space syntax method to determine tourist mobility in their research in the historical Kuala Lumpur region of Malaysia, and as a result of the study, it was revealed that integration with pedestrian movements can be increased with pedestrian-oriented activities along the road rather than the connections of the walking paths. In this context, it is necessary to develop urban designs that will ensure walkability in order to increase the attractiveness of the streets with high perceptibility in the historical city center. On the other hand, Kim and Sohn (2002), using space syntax theory, analyzed the urban street configurations of two areas in terms of their local structures and global contexts with different urban street configurations, and concluded that urban configuration affects the physical formation of cities. Balcı (2017) states that the value of a historical environment or an urban protected area is created not only by registered cultural assets but also by the holistic texture, character and sociocultural structure of these areas. In this context, it becomes clear that cultural tourism routes need to be developed in the area. Sustainability should be ensured throughout the city with these routes, which will be beneficial for urban development.

The structure of the street layout in residential areas is one of the most important factors that provides a sense of place to the space and shapes its design. It has been revealed that the accessibility of perceptible streets in Çankırı city center is also high. The relationships between street network integration and urban fabric provide data on usage experiences. Analyzing urban street textures with space syntax offers a quantitative approach to determining areas where tourism will be developed. As a result, it has been concluded that commercial areas in the historical area, traditional housing texture and common meeting areas shape the spatial configuration of the streets. It was found that the physical formation pattern of the space is affected by the social context. The study provides data to test the proposed methodology and compare it with other studies to examine the spatial characteristics of historical areas. Research findings provide a reference in solving the perception of tourists and improving the experiential qualities of historical streets depending on conservation plans in cities.

ABSTRACT

Along with the environmental problems brought about by the Warming Global, it offers different solutions in terms of protecting the natural balance and sustainability of biological resources. Green infrastructure systems are among those that stand out in these solutions. This approach causes not only the natural habitats but also the cultural living environments in the outside areas to be evaluated as a complex structure. In this context, it is of great importance on hard floors, which are part of the green infrastructure structure. It is seen that the precipitation waters flow away before they reach the level due to the increased construction and the amount of hard ground in recent times. Due to climate change, which is one of the leading environmental problems, the importance of water is increasing gradually depending on the time of our water resources. Trees of water within the scope of water management are very important in places such as landscape areas, irrigation waters and hard ground, which constitute a large part of water use, in order not to experience water shortage in the future or to prevent water use. Designing large-scale hard floors as permeable surfaces in urban areas includes evaluating these dimensions. The purpose of the use is to draw attention to how water consumption can be reduced with the dimensions of the permeable surfaces by designing these components properly and to draw attention to the importance of these showcases. The ecological and economic contributions of the permeable surfaces to the city in the regions that are detrimental to the literature structured to achieve this aim have been revealed.

Keywords: Urban Area, Ground Permeability, Water Management, Climate Change.

4. INTRODUCTION

Along with the environmental problems brought about by global warming, different solutions are put forward in terms of preserving the natural balance and sustainability of biological diversity. Green infrastructure systems are one of the prominent solutions. This approach causes the landscape to be evaluated as a complex structure, not only in terms of natural living environments but also in terms of cultural living environments in urban areas. In this context, hard surfaces that are a part of green infrastructure systems are of great importance.

Recently, due to the increasing construction and the amount of hard ground, it has been observed that rainwater flows away before reaching the soil. The importance of water is increasing in these periods when our water resources are decreasing due to climate change,

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

which is one of the leading environmental problems. To avoid water scarcity or reduce water consumption in the future, it is very important to store water within the scope of water management in places such as urban landscape areas, irrigation waters and hard ground, which constitute a large part of water consumption.

Hard soils, which cover large areas in urban areas, should be designed as permeable surfaces and should be evaluated in this context. The aim of the study is to draw attention to how water consumption can be reduced by appropriately designing these areas and increasing the amount of permeable surface and to the importance of these areas. In the study conducted for this purpose, the ecological and economic contributions of permeable surfaces in urban areas to the city were revealed, supporting the literature.

As a result of the opening of stream beds and natural basin areas to urbanization, the destruction of natural vegetation and the creation of impermeable surfaces (parking lots, pavements, asphalt roads, etc.), the water cycle is interrupted (Poletto and Tassi, 2012). Especially in dense urbanization areas, the flow rate and speed of water flowing on impermeable surfaces has increased and therefore the ability of water to seep into the subsoil has decreased (Lau and Mah, 2018). Especially in recent years, the increasing number of vehicles has created the need for parking. In this context, there are parking areas with a lot of impermeable surface areas, little green space, and no vegetative design. This situation increases the amount of impermeable surface.

In areas where urbanization is intense, the risk of flood increases as the water passing into the surface flow is quickly directed to streams. Acceleration of water flow in areas with intense urbanization creates floods, drought, poor water quality and negative effects on groundwater resources (University of Arkansas Community Design Center, 2010).

Increasing urbanization causes the flow channels of natural waterways occupied by buildings to change over time, the water mass passing to the surface flow increases, and the infiltration surfaces of the soil decrease. This situation makes settlements where urban development continues and has not been properly planned, vulnerable to floods and floods due to infrastructure systems (Erkal and Topgül, 2020).

Green infrastructure is a green space network consisting of interconnected natural, semi-natural and cultural areas designed and managed to provide ecosystem services, preserving ecosystem values and functions (Nature Conservation Centre, 2019). Unlike gray infrastructure, which uses structural systems, green infrastructure uses vegetation and soil to manage rainwater where it falls. "By integrating natural processes into the urban area, it provides solutions not only to rainwater management but also to problems such as flood reduction and air quality improvement." The basic principle of green infrastructure is the use of vegetative elements to provide ecosystem services (Fletcher et al., 2014). For the use of vegetated areas, the amount of green space should be increased, and impermeable surfaces should be reduced accordingly.

In this study, examinations were made through examples to reveal the importance of ground permeability in green infrastructure systems in urban areas.

Techniques used in the study, include examining publications on the subject (books, theses, reports, articles, congresses, symposiums, seminars, websites, laws, regulations, etc.), revealing the importance of ground permeability in green infrastructure systems within the framework of literature and source research, and evaluations through examples.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Studies revealing the importance of green infrastructure systems on ground permeability in urban areas were examined. In his study examining surface permeability in city parks, Eşbah (2006) stated that as the rate of permeable surfaces in a park increases, the level of ecological balance will increase and this park will provide more opportunities for biological activity, material and energy exchange. The same researcher showed that when this situation is the opposite, the ecological quality is low and the ecological benefits that such areas can provide to both wildlife and the city are limited.

Tennis et al., (2004) mentioned in their study that permeable floor coverings are important in reducing rainwater runoff and rainwater management.

In their study, Doygun and Kısakürek (2013) emphasized that unnecessary covering of park grounds with hard materials should be avoided, to improve urban parks ecologically. This data underlines the importance of urban parks functioning as green infrastructure in terms of ecological balance and sustainability.

The study by Korkut et al., (2016) reveals that rapid and unhealthy urban development leads to the increase in asphalt, concrete and glass surfaces in cities, resulting in a decrease in green areas and the gradual disappearance of permeable surfaces. This situation threatens underground water resources in urban settlement areas and causes climate change to be felt more effectively in cities. People, who are exposed to increasing population density day by day, face higher temperatures in cities where concrete and impermeable grounds increase and green areas decrease. This situation causes precipitation water to be lost through surface runoff and the urban heat island effect to occur.

In the study conducted by Irmak et al. (2017), it was revealed that grass-covered areas and impermeable surfaces change the temperature in residential areas.

In their study, Shin and Lee (2005) emphasized that urbanization and the transformation of green areas into hard grounds are the main reasons for the increase in surface radiant temperature.

The study of Bayramoğlu et al. (2019) shows that decreases in open green areas lead to changes in both natural cycles and the water cycle in the city. With the change in climate, urban rainwater is not sufficient in traditional water collection systems and the risk of floods and floods due to sudden rains has begun to be encountered. They emphasized that the best solution to this situation is to integrate permeable surfaces into urban systems when making urban design decisions.

Da Silva et al. (2018) emphasized in their study that when rainwater and roads in urban areas were designed as natural areas in Brazil, water accumulation on the surface decreased and water leaked into the soil. However, they stated that they experienced problems in the infrastructure of water drainage in regions with intense urbanization, and with the solution they proposed, the balance could be achieved in sustainable ways by slowing down the flow of rainwater, increasing permeability, and collecting water from surface flow.

In their study, Adigüzel et al. (2022) focus on the various comfort features that the climatic features of cities offer to their inhabitants. However, it emphasizes that today, the increase in building masses and hard/impermeable surfaces (concrete, asphalt, etc.) with high heat storage and conduction capacity leads to temperature increases at local and regional levels. The study states that impermeable areas (roads; hard surfaces: concrete, parquet, asphalt, etc., buildings)

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

that prevent water from meeting the soil increase long-wavelength radiation by storing high amounts of heat, and at the same time, high-rise buildings with a shadow-casting effect contribute to the increase in air temperature at night.

Apaydın and Ak (2022) examined the potential of hard flooring to increase the visual impact value in their study. In the study, based on the Psychophysical approach model, which is one of the landscape impact assessment methods, 18 different flooring materials in the photograph were used to evaluate (Concrete, Andesite, Gravel, Basalt, Grass stone, Rubber, Granite, Red Soil, Slate, Interlocking Concrete Paving, Sand, Log Mosaic, Marble, Travertine, Wood, Brick, Asphalt).

- For a natural and harmonious appearance; wood, basalt, travertine, andesite, and grass stone materials,
- For a regular, clear, and perceptible appearance; andesite, basalt, granite, grass stone, travertine, and wood materials,
- For a lively and exciting look; log, grass stone, slate, travertine, gravel, and wood materials,
- For a look that feels safe; andesite, basalt, travertine, wood, and granite materials,
- For a relaxing, peaceful, and calm look; Granite, wood, basalt, and andesite materials
- For an impressive and beautiful appearance; wood, basalt, andesite, slate, grass stone, travertine, and log materials.

These examples represent different applications of permeable hard surfaces. Such surfaces offer significant advantages in terms of water management, environmental protection and sustainability, air quality, aesthetic value, sound insulation and zero liquid waste. Permeable hard surfaces can be used in urban areas, parks, parking lots, bicycle paths, gardens and other areas and are also very important as part of an environmentally friendly sustainable design approach. However, while permeable surfaces have many advantages, they also have some disadvantages that should not be ignored, such as the need for maintenance, durability, installation cost, and risk of leakage.

5. CONCLUSION

- Rapid and unhealthy urban development increases the number of hard surfaces in cities due to concrete, asphalt and glass surfaces, causing a decrease in green areas and ultimately the gradual disappearance of permeable surfaces. This situation threatens underground water resources in urban settlement areas and causes climate change to be much more effective in cities. In cities that are increasingly exposed to more human density, become more concrete, have more impermeable grounds and fewer green areas, sensible temperatures increase, rainwater is lost through surface flows, and the urban heat island effect emerges.
- Rapid urbanization also affects the natural water cycle in cities. Climate change in recent years and the corresponding decrease in open green areas have affected the urban ecosystem. In order for the urban ecosystem to be sustainable, there must be a certain amount of urban open green areas. In this sense, cities are called impermeable with hard ground coverings and permeable surfaces with open green areas. For this reason,

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

permeable and impermeable surfaces must be in certain proportions and arrangements in the urban planning system. Creating permeable surfaces in urban areas can be achieved through designs compatible with nature. The most appropriate way to stop the risk of floods in urban areas by stopping the water flowing to the surface due to excessive rainfall is to create green areas using landscape components or to use permeable surface coatings. This situation is created by harmoniously planning urban infrastructure systems and landscape elements as a result of the hydrological cycle. When evaluated in this context, permeable surfaces are provided by using green infrastructure system elements in contemporary sustainable planning approaches.

6. RECOMMENDATIONS

- Care should be taken to ensure that the grounds other than the mandatory hard grounds in the urban fabric are permeable as much as possible for example, impermeable stone, asphalt concrete, etc. on parking lot floors. Instead, stones with grass joints or stepping stones should be preferred.
- The use of surface coatings with low heat absorption on floors should be preferred in terms of both bio-comfort and energy-efficient landscape designs.
- Precautions should be taken to prevent soil layers on permeable surfaces from compaction and moisture loss so that surface waters can infiltrate underground and feed underground water resources.
- Rainwater in the city should be included in the water cycle by creating permeable surfaces, preventing contamination of groundwater by surface runoff from impermeable surfaces.
- Floors that are permeable materials produced with new technology should be given more space in applications.
- To make existing floor coverings permeable, studies should be carried out on improving them using new technology and different methods.
- Appropriate size gratings should be used instead of impermeable surfaces used around trees.
- Permeable surfaces and green areas should be increased in the designs of open parking areas.

At the same time, “holistic” approaches should be considered for the city as a whole. At this point, holistic approaches such as green roads, green infrastructure and green networks should be especially evaluated against structural and functional changes and deteriorations in spots and corridors.

ABSTRACT

With the increasing urbanization recently, the pressure on natural resources is increasing. Increasing construction and inaccuracies in land use cause the fragmentation of landscape animals. To eliminate the negative effects of the parts, these areas needed interconnected connections. It has revealed the green road concept made in this direction. Green roads meet recreational needs as well as cultural and ecological continuity in cities. Karadeniz Technical University (KTU) Kanuni Campus and its surroundings were chosen as the study area. KTU Kanuni Campus, which has natural and cultural values for the city of Trabzon, has many ecological and economic contributions to the city in terms of being an inner-city University campus. From time to time, the increasing population density and the dense construction around the campus caused the fragmentation of green food. The fragmented green areas affect urban life protection, ecology and biodiversity negatively. To minimize these negativities and increase the protection of urban life, it is aimed to connect the fragmented green areas of KTU Kanuni Campus and its surroundings and to organize the green road system together with natural areas. To achieve these goals, the study was carried out in three stages: literature review and inventory studies, analysis study, determination of focal points for the green road and determination of the route for the connection. As a result, in this study, suggestions were developed in addition to creating a comprehensive greenway system by determining the most suitable routes in line with greenway planning strategies and goals.

Keywords: KTU, Green Way, Recreation, Planning.

1. INTRODUCTION

Greenways are networks containing linear elements, planned for many different purposes, and compatible with aesthetic, ecological, cultural, recreational or sustainable land use (Ahern, 1995). According to Fabos (1995), it is defined as interconnected corridors of different widths, such as highways and railways. Green roads also protect natural resources, alternative transportation, habitat for plants and animals, etc. They are natural corridors separated to create areas and can be used for many different purposes (Bryant, 2006). Greenways are a unique type of open space planned for multi-purpose purposes. Various definitions have been made regarding this concept. The European Green Roads Association defines green roads as communication roads that are reserved only for non-motorized transportation and improve the quality of life in the surrounding areas (Senes et al., 2017).

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium **September 14-15, 2023, Naples, Italy**

Greenways represent the integrity of linear open spaces planned for recreational, ecological and cultural uses, and they are protected and managed for these purposes. While most of the greenways have recreation or nature protection purposes, some are planned to cover both purposes. Green paths planned for recreation purposes provide opportunities for walking and cycling paths, organized sports areas, and group activities. In addition, green paths that interact with each other provide a rich experience that follows natural corridors as well as historical and cultural objects. These definitions emphasize that greenways represent a multifaceted planning and use approach. Greenways serve as an important tool for nature conservation, for people to participate in recreational activities and to explore cultural heritage. Therefore, green road projects are considered important resources for the environment, health, culture, and welfare of society. Green roads have many functions such as protecting biodiversity, managing water resources, protecting historical, cultural and natural resources, and providing a living environment for plants and animals. In addition to these functions, green roads also contribute to the city in which they are located in many ways (Zengin et al., 2019).

Greenways are used as tools to combat land degradation, fragmentation, urban growth and uncontrolled land use for sustainable landscapes (Ahern, 1995; Little, 1995; Liu et al., 2018; Viles and Rosier, 2001).

- Greenways created with vegetal fences and river edge lines in agricultural areas offer significant environmental benefits in agricultural areas by preventing erosion and surface runoff, ensuring more efficient recycling of nutrients and offering microclimatic advantages. These benefits enable storage by reducing wind speed and contribute to the increase in atmospheric and soil moisture levels (Forman and Godron, 1986).
- Greenways can combine cultural and ecological resources with the ability to create a network that has more potential for use and is more valuable than the sum of its parts, in terms of landscape synergy (Viles and Rosier, 2001).
- The ability to connect urban habitats and the biodiversity associated with these habitats provides opportunities for positive interactions between humans and nature in densely populated cities, as previously emphasized by Ahern (2013) and Bryant (2006) (Gobster, 1995; Chon and Shafer, 2009).
- Green roads, which are used to increase the quality of life of individuals, serve as a basic transportation network for transportation to daily activities such as work, school or shopping, as stated in the study by Keith et al. (2018) (Rovell et al., 2020).
- Greenways can provide healthy environments where individuals can regain well-being experiences and explore and satisfy various active and passive recreational needs and desires (Fabos, 1995).
- Greenways can help provide environmental benefits such as increasing soil strength, contributing to water purification, providing flood control, and improving air quality (Anthony, 2006; Qin, 2012; Liu et al., 2018).
- It can be said that linear forms of recreation, such as walking and cycling, have the potential to fulfill environmental and social functions (Gobster, 1995).
- Areas such as stream corridors, defunct canals, abandoned railways, power lines and road networks are defined as potential greenways (Gobster, 1995).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

- In areas where green roads function as green belts, they contribute to controlling their development, reducing pollution, and improving and protecting the landscape (Viles and Rosier, 2001).
- Green roads also can provide suitable areas for nature education (Viles and Rosier, 2001).

Greenways also function as tools to combat land degradation, fragmentation, urban growth and uncontrolled land use changes for sustainable landscapes (Ahern, 1995; Chen et al., 2017; Zengin et al., 2019; Karaşah, 2020). Green roads such as vegetative fences and river edge lines created in agricultural areas provide prevention of erosion and surface runoff in agricultural areas, increased nutrient recycling, and microclimatic (reducing wind speed, increasing soil moisture, etc.) benefits (Forman and Godron, 1986).

Greenways, industrialization, rapid population growth, etc. are vital concepts in cities that grow and lose their green areas for various reasons. In such cities, they are multifunctional linear green areas that connect different ecological areas to protect the integrity of natural ecological systems and prevent the fragmentation of habitats (Little, 1995; Liu et al., 2018).

In addition, while ensuring the sustainability of important ecological and cultural areas in and around the city, it also offers alternatives to city users in their limited recreational areas. Therefore, it is of great importance in both protecting natural resources and promoting healthy lifestyles (Panneerhelvam et al., 2020). Greenways are not only roads used to get from one point to another but also an environment for activities and experiences (Taylor, 2015; Rovelli et al., 2020).

This study, carried out in this context, aimed to create the proposed green road plan for KTÜ Kanuni Campus and its surroundings, based on the important green areas of the city, recreation areas, tourism and recreation areas, roads, streams, and water surfaces. By including the opportunities offered by natural and cultural resources in the green road plan in a balance of protection and use, it aims to support the green infrastructure system of the city and offers an area for recreational activities to campus and city users.

2. MATERIALS and METHODS

The study area border includes KTÜ Kanuni Campus and its surroundings, located in the Ortahisar district of Trabzon City (Figure 1). In the study, in addition to photographs obtained from field studies, Google Earth satellite images and software such as ArcGIS, AutoCad and Photoshop were used as materials.

Figure 1. Study area location map (a. Türkiye, b. Black Sea Region, c. Trabzon, d. KTÜ)

The method of the study has three stages. In the first stage, local and foreign literature searches were conducted regarding the green road concept. In the light of research data, the method was decided by making use of studies on green roads. After selecting the most appropriate method for the area, field studies and analysis of the area were carried out. At this stage, research method and GIS techniques were used. In the final stage, area change maps were created through GIS techniques by evaluating the data obtained from literature research and analysis, and focal points and connection points were determined with the help of field studies and Google earth. In the light of this data, potential green road suggestions were developed. While determining the routes, important intersections and median arrangements that ensure the continuity of the green system around the study area, Trabzon coastal road, important focal points that take into account pedestrian and bicycle paths were considered.

3. FINDINGS

In the study, firstly, literature review and field studies were carried out. During the studies, the changes in the natural and cultural elements in the area were detected, and the changes from the establishment of the area to the present day were revealed with images taken from Google Earth (Figure 2) and evaluations were made. As a result of the evaluation, urbanization rates and fragmented green areas were revealed (Table 1), and important focuses and impact zones in the area were determined. To connect fragmented green areas, two different suggested connections have been provided in the area.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

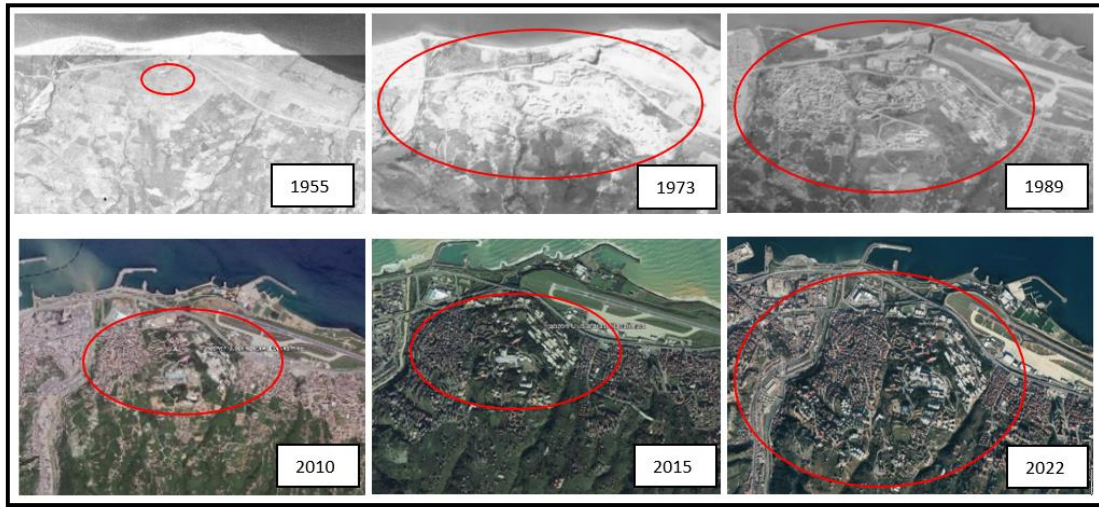

Figure 2. Satellite images of the study area according to years

Table 1. Structural and vegetative changes occurring in KTÜ Kanuni Campus and its surroundings

	1955	2022	CHANGE
GREEN AREAS	247.000 m ²	127.000 m ²	-%48
HARD GROUND	814.118 m ²	934.118 m ²	+% 14,7
RESIDENTIAL AREA	-	709.814,78 m ²	
TRADE AREA	-	83.814,95 m ²	
TRANSPORTATION NETWORK	4.820,84 m	58.556,77 m	+% 1114

The changes in the Kanuni Campus and its surroundings were revealed through Google Earth and the maps created. In the light of this data, it was observed that the green areas in the study area became fragmented (Figure 3).

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

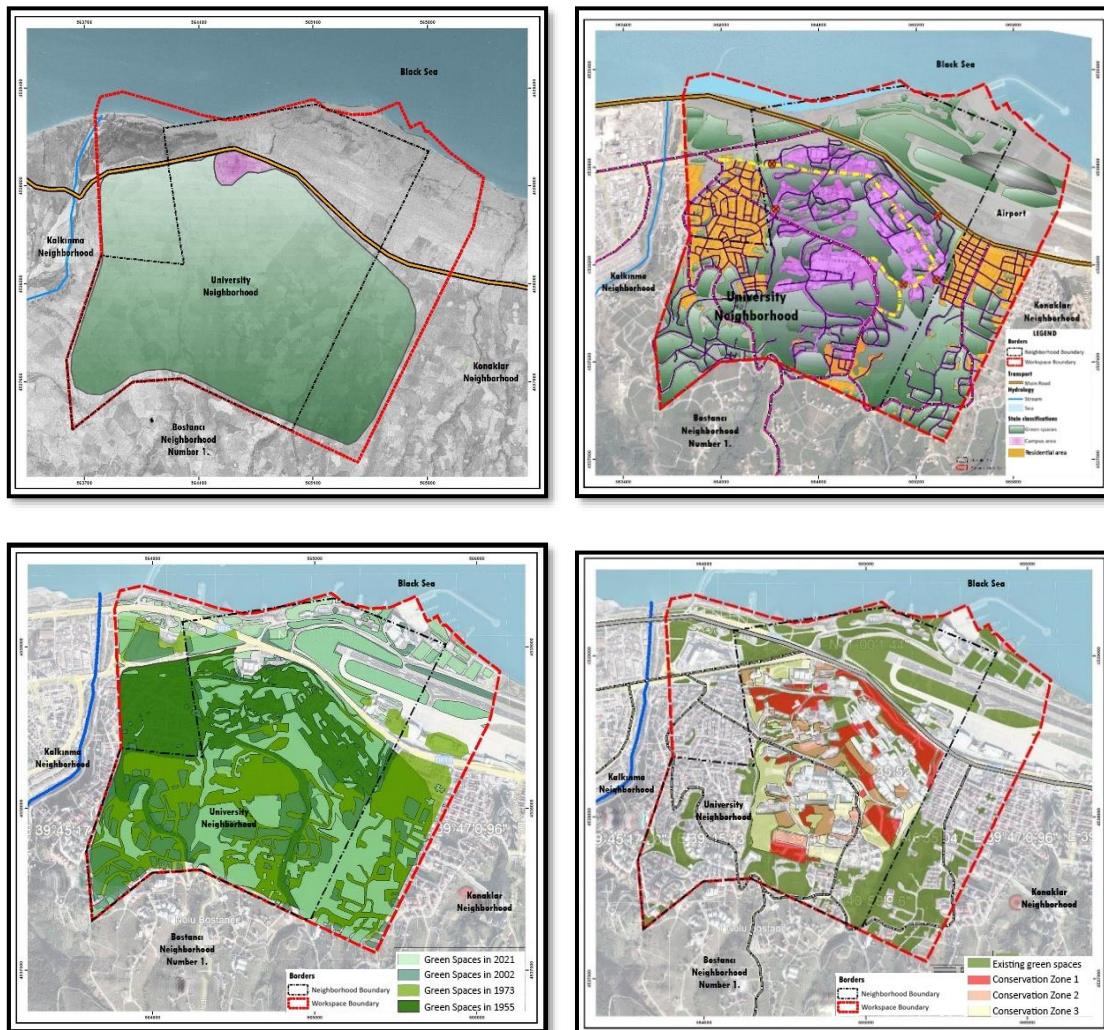

Figure 3. Green area fragmentation in KTÜ Kanuni Campus and its surroundings between 1955 and -2022

It was determined that in 1955, the year of establishment of the KTÜ Kanuni Campus, the construction was only within the campus border and there were no buildings around it, the green areas were in one piece and there were generally agricultural areas around it. As the campus began to develop, it was observed that the construction within and around the campus border increased and green areas became fragmented. As a result of the fragmentation and loss of green areas in and around the campus, in order to create integrated planning with its surroundings, parks, squares and roads that are heavily used in and around the campus were identified and a green road proposal was developed to connect these areas (Figure 4). Considering similar areas, the green road system was planned and the necessary connections were strengthened. Many different recreational activities have been defined, such as alternative transportation to these areas with green roads, biodiversity, pedestrian-oriented transportation, viewpoints, recreation areas and bicycle paths.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

environmental pollution in today's cities, insufficient surface flow control and difficulties in accessing green areas are due to lack of planning. Therefore, it is of great importance to integrate greenway plans into planning studies and decision-making processes at all scales.

In the greenway planning proposed for the campus and its surroundings, it is proposed to plan a greenway with an area of 5.5 km (8 km afforestation area on both sides) starting from the main line of the campus and extending to the long street. Considering that 800 trees are planted at 10 m intervals in the green areas planned to be created within the scope of the green road, approximately 310,550 \$ of carbon storage gain is achieved (Figure 5).

Figure 5. Greenway planning proposal 1

- The 2nd alternative way for greenway planning could be a greenway planning starting from the main line of the campus and extending from the beach to Ganita Park. On this line, an ecological bridge can be planned to pass from Gate A to the beach, and then continue as a green road. This could be a transportation line that includes approximately 4 km of green road and 500 m of ecological bridge. In the green area calculation made in this context, $4 \text{ km} * 2.40 = 9600 \text{ m}^2 + 500 * 2.40 = 1200 \text{ m}^2 = 10$. It has been determined that a green area will be added to the 800 m² campus. Although this amount of green space has been increased, the amount of green space on the campus does not reach the standards. The amount of green space required for green areas to be 10 m² per person is 233,000 m². In short, considering that a 2.4 m wide road was built to have sufficient green space per person, it covers approximately 97 km (Figure 6).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Figure 6. Greenway planning proposal 2

- Appropriate plant species should be selected along the greenway to increase biodiversity and ensure the continuity of nature. In this way, users will move away from the impact of the dense hard ground and get closer to nature, and the sustainability and ecological value of the area will be increased.
- With ecological greenway design, a pedestrian-priority transportation axis that includes alternative transportation systems can be provided. Thus, the carbon and heat island effect can be reduced in and around the campus.
- Planting should be done by the ecological conditions and physical structure of the region, and plant areas that are representative or need to be protected should be excluded.

In this study, the routes recommended to be planned as green roads are; It aims to provide various ecosystem services to campus and city users by integrating fragmented green areas for the campus and its surroundings.

As a result, by correctly planning such routes, the destruction of natural areas will decrease and qualified green areas will be created. In this context, by planning green roads, ecological and economic contributions to the city will be provided by offering recreational opportunities to users and at the same time preserving landscape values (natural and/or cultural). The importance of green roads is revealed by the formation of such qualified areas.

ABSTRACT

Palestinian villages were one of the arenas severely affected by the British occupation in 1918 and then the establishment of the State of Israel in 1948. The brutal occupation has been destroying villages and displacing their people to control Palestinian territories. Hundreds of villages were destroyed, and their people were expelled. Consequently, many architectural and urban records of Palestinian history and its of cultural, political, and social aspects were lost. But the worst also occurred with the separation between the Palestinians on both sides of Israel borders since 1948. Generations outside the borders grew up on what remained of the memories of their fathers and grandfathers and the images of the Palestinian villages and their houses. Palestinian students of architecture lost the ability to interact with these spaces and structures necessary for the development clear understanding of Palestinian architecture. This research presents an effort attempted by the author to use the phenomenological approach to connect students of architecture at the Islamic University of Gaza to Palestinian architecture. An important part of the exercise was directed to village dwellings remained in Israel after 1948. The phenomenological approach proved useful in helping the students understand Palestinian architecture from the available digital images and photographs available for the village dwellings. The students used their phenomenological cognition to produce architectural drawings for these dwellings which continue to represent a useful source on Palestinian architecture.

Keywords: Palestine, Village, Architecture, Phenomenology.

1. INTRODUCTION

Historical architecture is considered one of the most important and authentic records of the history of societies and their cultural, economic, social, and political movements (UK Archive, 2023). This is because it is one of the greatest records of human settlement on earth, the longest in time, and the most surviving evidence throughout the ages. Vernacular architecture is distinguished from the architecture of the elite. It is widespread in place and has the deepest influence on the people because it houses most of them (Arome and Çagnan 2021). It is the most faithful in expressing the conditions of societies because it was built by the people for the people to provide shelter and refuge. In contrast to the architecture of the elite, which is built by distinct members of society to express themselves and their political, economic, social, and cultural powers. It also often expresses luxury, extravagance, and corruption (Hnin, 2022). In many cases, it is unjustly built from people's money, but not for their sake. In other cases, it expresses authoritarian power for the purpose of dominating society and controlling its capabilities.

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

In Palestine, the village was and still is one of the important and influential Palestinian spaces in history. It was and still is in modern history a wide arena for the hidden and declared conflict over the Palestinian land since the beginning of the Zionist project and the British Mandate (Al-Ju'beh, 2008).

One of the most prominent features of the Palestinian village is its distinctive urban texture (Carabelli, 2019). The placement of villages in their places depended on the nature around them, as they merged into the geography of the place and its history in a unique organic manner. The elements of the village structure were distributed in harmony with the natural environment and the social and cultural settings. As for its architecture, it represented the truthful and pure expression of Palestinian culture, its artistic formations, its visual compositions, and the skill and creativity in the use of building materials and construction techniques (Al-Ju'beh, N. 2008).

On the other hand, the Palestinian village was one of the arenas severely affected by the British occupation in 1918 and then the establishment of the State of Israel in 1948 (Ginat, 2018). The villages and their land were the largest area of Palestine, and therefore controlling the villages and their land represented an important goal to control the country. Occupation brutal powers have been destroying villages and displacing their people to achieve this goal. Hundreds of villages were destroyed, and their people were expelled. Consequently, many architectural and urban records of Palestinian history and its cultural, political, and social aspects were erased.

Not only that, but the worst also occurred with the separation between the Palestinians on both sides of Israel's borders in 1948. Generations grew up on what remained of the memories of their fathers and grandfathers. Many efforts were directed to write down these memories in books, stories, anecdotes, and poems. Yet, on the other hand, these generations lost the experience of real living coexistence with urban spaces and the architectural structures of those lost lands. Consequently, Palestinian students of architecture lost the ability to interact with these spaces and structures necessary for the development of urban and architectural creativity and the associated patterns of Palestinian culture and history. Those who grew up in Gaza Strip after 1948 were less fortunate than those of the West Bank. Gaza Strip, since World War I, has been suffering from economic and political problems that affected various cultural and social aspects, including patterns of urban development and architectural formation. This situation worsened after 1948 and continued after 1967. The urban and architectural separation left its traces on the artistic and cultural conscience of those generations over the years without any attention being paid to the need to address this situation, nor to the appropriate methods for such treatment. In 1993, the Department of Architectural Engineering was established at the Islamic University of Gaza, which started to contribute, albeit in a limited way, to building the urban and architectural awareness of the new generations of architecture students. However, the study plan of the department did not include a specialized course in Palestinian architecture to provide an integrated systematic study to build students' self-awareness of Palestinian architecture and its characteristics. This remained the case until 2007, I was the first to suggest to the department that such a course should be offered due to its great importance and because the architecture department in any Palestinian university should seriously be committed to offering this course with this name. The head of the department at the time, Dr. Farid Al-Qeeq welcomed the proposal and insisted that I should teach the course. It was quite a challenge. Not only in determining the study material for the course but also because most of the students did not Gaza Strip and their urban and architectural experience of the Palestinian architecture remained confined to refugee camps and overcrowded cities that lacked the standards of good

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

urbanization. They did not have the opportunity to live with any model of historical Palestinian architecture, except the few old houses that still exist in the old city of Gaza and very few remain in other cities. It is true that the study of history, including the history of urbanization and architecture, is usually done theoretically by studying the available written sources, but because human awareness is restricted to the spatiotemporal frameworks drawn by the elements of urbanization and architectural formations, the spatiotemporal coexistence of architecture is considered one of the most important tributaries of its awareness and understanding. This was not available, but there was a unique opportunity to apply a distinguished experience to compensate for this deficiency through the phenomenological approach in architecture, which I also was the first to teach in 2006 in the same department as a separate course. Within this very special context of students of architecture at the Islamic University of Gaza and their study of the Palestinian architecture of the occupied villages, the phenomenological approach provides a unique opportunity to explain Palestinian architecture to the students from one side, and the other side to understand the reactions of the students towards this architecture. Through several years, many dwellings were studied in tens of villages in 1948-occupied Palestine and 1967-occupied Palestine. The concern mainly was directed to the districts of Jerusalem and Al Khalil (Hebron) and Gaza City and its environs. This article studies 11 villages in the Jerusalem district.

Phenomenology

Giving a specific definition for phenomenology is a challenge especially if it is to be directed to people outside the circle of philosophy. Phenomenology appeared as an intellectual movement in the early twentieth century by the philosopher Edmund Husserl, and then by his student Martin Heidegger. Then it became one of the important trends in looking at, studying, and analyzing phenomena of the world. Husserl believed that phenomenology is a subjective process that depends on perception. Awareness is the basis of perception and self-realization requires the existence of the phenomenon in front of it. Husserl used the term world of life to refer to the world of self-interdependence that precedes our theoretical experience of natural phenomena. At the same time, Husserl believes that objective, empirical, natural experience is nothing but the product of human factors and their related aspects of culture and society. Accordingly, the phenomenological approach moves away from the rigid rules of the experimental approach. It relies on the researcher himself who records his impressions of the phenomenon and how he experiences it in the reality of the life world without any hypotheses about the phenomenon. This highlights the importance of the relationship between the researcher and the phenomenon. Thus, the outcome of the phenomenological approach will be narrative analytical studies and not the conclusions of objective tests. (Teodosio, 2005).

The phenomenological approach uses sensational perception to explore the phenomena and their relationships with the people and then tries to understand the sensational reactions of these people (Maveety, 2008).

On the contrary, Heidegger looked at phenomenology as a method of perception that does not require the presence of the self in front of the phenomenon. He describes phenomenology as the way to allow what shows itself to be seen through itself. For him, phenomenology is not primarily about the phenomena that we want to study, but rather about the way in which we study these phenomena. Phenomenology is a method for exploring the hidden sides of these phenomena and making them manifest themselves. In this regard, Heidegger believed that man

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

is distinguished from other species because of his spatial relationships with his world. This world, according to Heidegger, is divided into material phenomena and non-material phenomena. Material phenomena include original natural phenomena such as the sun, moon, earth, and sky in addition to man-made phenomena, such as buildings, roads, and squares. Non-material phenomena also include feelings, sensations, habits, traditions, ideals, and principles. Heidegger considered that this world existed before man. Then his struggle started for the making of place and the creation of space and integrating them with the physical and human environments. These places and spaces represented the world of daily life in which he grew and developed. (Gonabadi et al, 2020).

The philosophy of Modernism did not prove viable for explaining the phenomena of life, especially those that are connected to people and are related to their social and cultural aspects. As such, architecture cannot be understood only through the material components. Because there is always more than that, people who make this architecture and those who use it, all have their personal, communal, social, cultural, and psychological characteristics. For such kind of complex relationships, phenomenology provides a suitable approach for its study, analysis and understanding. This approach rejects the adoption of natural sciences as the sole means for the development of human knowledge. It relies on reflective and intuitive thinking that does not depend on any prior assumptions to develop knowledge. The phenomenological approach is not empirical. Phenomenological knowledge cannot be obtained through experimentation and objective analysis, as there are always subjective human aspects that have an impact on guiding knowledge development. Phenomenology is a descriptive cognitive approach that deals with the phenomena of existence through study and analysis to reach the hidden secrets and meanings that surround them. The phenomenological approach is one of the descriptive analytical research methods that aims to explore the secrets of the hidden phenomenon and its hidden meanings and implications.

Phenomenology and architecture

The history of architecture cannot be confined only to the history of building materials and methods of construction, but it is the history of ideas produced by society and culture. Every society has its own culture that distinguishes it from others. (Ehrett, 2023). The post-modern and post-positive period usually looks at the products of architecture and the built environment in general with its functional components and structural calculations. While the phenomenological approach searches in these products for the meanings and ideas that guided man during their production. This is evident in Husserl's saying that awareness of the world is not merely passive acceptance of what is in it but is active and intentional participation in the formation of what is in it. This is exactly what applies to studies of architecture, which should not limit architectural creativity to the means and materials of producing the built form but must include the human interactions that contributed to its production (Teodosio, 2005).

The Phenomenological approach reveals the spirit of the phenomena. Through this approach, we better understand the sensory perception of architecture and the built environment, or in other words, the sense of architectural space and the sense of architectural place. Both space and place have expressions, symbols, meanings, and secrets formulated by the culture and social structures of their makers. (Maveety, 2008).

The spirit of architectural space and the spirit of the urban place express themselves in the world of existence through their spatial components of floors, walls, roofs, and materials with their

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

colors and textures. They also have the natural aspects that interact with them such as shadow, light, darkness, heat, cold, humidity and air. (Maveety, 2008).. All these elements and aspects refer precisely and specifically to the content, concept, and rhythm of the world of daily life, which people usually do not pay attention to, nor to its details. This world cannot be imagined without the human being in it. (Simon, 2000).

Phenomenology of the dwelling and sense of place

The dwelling represents an objective existential phenomenon of our life world. Heidegger was the first to introduce the philosophy of dwelling into phenomenology. He linked the existential nature of the dwelling to the life world or the world of daily life. The phenomenon of the dwelling has existential reality which all people perceive in the same way. It has architectural realities that people differ in their perception because of the differences in their emotional and sensational contents. And because of the many meanings and ideas that are reflected by them. This is in addition to the specialties of human subjective frameworks such as culture, society, and politics.

Man has been associated with the dwelling since the dawn of history, from the day he came out of the cave and looked for a place in the space that extended before him. He began making the place of the dwelling by choosing a specific location of land to be suitable for establishing the new shelter. This choice and preparation were not merely mechanical or environmental though it had these characteristics. It was the sense of place that led to the decisions of where and how to delineate this place. The search for meanings responded to what he wanted to see and learn and what he wanted to know and explore. There also were the feelings and emotions for making the place to be loved, looking good, and seemed viable. This initial stage was then followed by the creation of the architectural space of the dwelling. He built his first primitive structure not only as a shelter. He didn't just come out of the cave to make a shelter. Shelter, refuge, and protection were probably more fulfilled in the cave than in the hut. But he wanted to express his being in this world. He wanted to go out into the vast emptiness of space and interact with it responding to the interactions of feelings and emotions in his heart, and thoughts and visions in his mind. From here, the dwelling and its organic connection to man was created. It is not possible to look at the emergence of architecture without a careful understanding of this relationship before looking at its material components (Maveety, 2008).

As an example, the round houses of Britain which are dated from the Bronze Age throughout the Iron Age illustrate this reflection of dwelling. This dwelling reflected the very primitive existential perception of the round horizon around the sight of the human.

The dwelling represents the most important type of human interaction with the environment and the life world. It is the basic form of being in the world as invented by Heidegger. Despite the many studies that dealt with the dwelling from its cultural, social, psychological, and engineering aspects, few dealt with the basic philosophy of the establishment of the dwelling and the symbols and meanings associated with each dwelling that distinguish it from the other. Among the many approaches that dealt with this subject, the phenomenological approach stands out in its ability to explore what is behind the physical structure of the dwelling in terms of these meanings and indications.

According to Heidegger, the dwelling establishes the relationship between the cosmological world, the anthropological man, and the structure of the dwelling. This relationship includes

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

various transformations in man's relationship with the world of the dwelling: from existence to presence, from presence to settlement, from settlement to place, from place to dwelling, and from dwelling to place. Christian Norberg-Schulze is considered one of the best in the study of analgesic phenomenology.

In his book: *The Present - Language - Place* (2009), he showed that limiting the dwelling to the quantities of materials used in its construction is limiting its value to the mere walls, ceilings, and floors that make it up, emptying it of the spirit of place, and the absence of the meaning of being. (Gonabadi et al, 2020).

Edward Ralph believes in his book *Place and Nowhere* (1976) that a dwelling loses its meaning if it cannot have a sense of place in the location in which it originates. (Gonabadi et al, 2020)

Regarding the Palestinian village dwelling, it is a special representation of the phenomenological meaning of dwelling. It shows how the architecture of the dwelling evolved from the human consciousness of architecture in a compatible way with his existential meaning he found himself adopting it by nature. The Palestinian villager built his dwelling from his perception of his relation to his land. He wanted to feel a deep sense of place by taking care of his land in a meditative way to make himself an existential part of the safety and belonging found in the basic relation of humans and land.

Key approaches in phenomenological research

Phenomenological research has special concerns on the suitable ways for dealing with the phenomena of the lived world and the world of everyday life. The special connections between the phenomena, people, and the researcher require suitable frameworks of inquiry that are sensitive to issues like subjectivity and prejudice. Yüksel and Soner (2015) introduced 6 approaches to phenomenological inquiry. They include Lived Experience, Intentionality, Epoché, Phenomenological Reduction, Imaginative Variation, and Co-researchers (Yüksel, 2015).

This research used 2 approaches. The first was the lived experience approach. The students were for the first time subjected to the Palestinian traditional village dwellings and their distinguished architecture. This approach investigates the lived experience of students with the phenomenon of the Palestinian village dwelling. It is their first time and first-hand experience of the phenomenon and their actions and reactions, activities, and behaviors were observed. The second approach was Imaginative Variation.

The students were trained to use their imagination to produce their pure original designs for the dwellings concentrating on the relationship between it and the surroundings to express the sense of space of the dwelling. At the same time, we examined the 3Ds of the dwellings produced by the students and used our imagination to assess their perception of the sense of place of the dwellings.

2. MATERIALS and METHODS

The course Palestinian Architecture was given to 2 separate groups of male and female students according to the education system at the Islamic University of Gaza. 18 female students worked in the villages of Jerusalem district. The villages were chosen randomly from the list of the district villages. None of the students has ever visited any of the villages or any other similar villages in Palestine. The main source for photos of villages in 1948-occupied Palestine was the

September 14-15, 2023, Naples, Italy

website [Palestineremembered.com](https://palestineremembered.com/)- <https://palestineremembered.com/> . The main source for photos of villages in 1967-occupied Jerusalem was the website of Riwaq - Centre for architectural conservation- <https://www.riwaq.org/home> , and its registry of historic buildings, <https://www.riwaq.org/riwaq-register/registry-historic-buildings> . Students also were free to search for information on these villages and their dwelling architecture from any other resources. Their task was to experience the architecture of the village and to prepare plans, sections, and elevations of at least 2 examples of dwellings based on the photos of the village. Special attention was paid to the production of 3D images of the dwellings. They were free to choose any available means of visual presentation. Discussion, presentations, and narratives continued for the whole semester.

3. FINDINGS and DISCUSSION

The exercise was very exciting. When Palestinians talk about their history, country, land, and architecture they feel great stimulation. The students were raised under occupation and their lived experiences were occupied with brutal aggression. Their life world did not exceed the tiny area of Gaza region of 360 km² sieged from two sides by Israel, from the south by Egypt, and from the west by sea. The exercise gave them a chance to have a new lived experience in the classroom with the virtual architecture of the Palestinian village. It was a tough struggle for me and them. I studied, worked, and lived in the West Bank and visited Jerusalem and its environs several times. I also visited several Palestinian cities and villages in Israel. Yet these young students never did. They struggled very hard to be immersed in the life world of the Palestinian village to understand the atmosphere of its urban structure and architectural detail. How could they have a lived experience in an imagined built environment? How could they feel the sense of place of imagined places? How could they feel the sense of architecture without being immersed in its space?

The following discussion of the students' work sheds more light on these questions.

The images of Sataf village (table 1) used by the student clearly show a strong relationship between the dwellings and the village atmosphere. They show the organic relationship between the dwelling and the context. Students were free to use any means of visual presentation for their dwellings. This one (and all the others as will be shown later) used SketchUP software. The 3Ds were bare and bold volumes of the dwelling without any sense of life or significance or relationship with context. The type of figures, trees and grass are not Palestinian. They even lack the sense of nostalgia, the sense of pride, or the storytelling of any life feature of the village dwelling.

Sataf village (1948-occupied Jerusalem)- General images of the village

Images of inspiring houses and remains

3Ds of students' imaginations of the houses

Although the Deir Yasin village photos (Table 2) show several elements that represent the richness of lived experience in the spaces of the dwellings and between them in this village, students represent the dwellings as separated units without the richness of the original photos. The plants used in the context are not the same in the images of the village.

It is worth mentioning that this village specifically is linked to a massacre in 1948 that lived with despair and grief in the memory of every Palestinian.

Table 2. Reconstruction of Palestinian Dwelling in Deir Yasin Village

Deir Yasin village (1948-occupied Jerusalem)- General images of the village

3Ds of students' imaginations of the houses

It is noticed that Lifta village (Table 3) has a unique sense of place which put it on the list of UNESCO's tentative World Heritage Sites. It has many inspiring house compositions. On the other hand, when students re-imagine the sense of place here, they cannot reflect the sense of natural landscape that surrounds the dwellings. However, this result emphasizes the effect of the forced displacement of the ancestors of the students from their original land.

Table 3. Reconstruction of Palestinian Dwelling in Lifta Village

Nataf village images (Table 4) raise the notion of internal space cognition and its relation to the outer original space in the Palestinian village. The construction system used, the raw building materials, and the other elements distinguished the Palestinian dwelling was remodeled by the students in their try to experience the sense of living inside the village dwelling. It is noticed that they reflect the elements they noticed in the images, but they still cannot connect it to the overall sense of place that represents the unique duality of indoor-outdoor spaces in the Palestinian village.

Table 4. Reconstruction of Palestinian Dwelling in Nataf Village.

Nataf village (1948-occupied Jerusalem)- General images of the village

3Ds of students' imaginations of the houses

The general photos of Ain Karem (Table 5) village show that the village's full perception is inherited in its natural intricate components of hills, trees, rocks, and dwellings.

The students who work here show their perception of the dwelling as perceived from the monochrome image. The student did not reflect his sense of the material of this dwelling.

Table 5. Reconstruction of Palestinian dwelling in Ain Karem village.

Ain Karem village (1948-occupied Jerusalem)- **General images of the village**

Images of inspiring houses and remains

3Ds of students' imaginations of the houses

The images of Beit Mahsir (Table 6) inspiring houses show how these two houses are rich with Palestinian dwelling elements. Here, the student reflected on the details in his imagination of the house. However, it is noticed that they could not catch the full perception of the context of the Palestinian dwelling in the village. This is due to the altered sense of place that is caused by the occupation and the dramatic disconnection it made in the whole Palestinian life-world experience from that time till now.

Table 6. Reconstruction of Palestinian dwelling in Beit Mahsir village.

Beit Mahsir village (1948-occupied Jerusalem)-

The cubic form of the inspiring remaining house of Deir Aban (Table 7) village was illustrated by the student via a 3D program with different proportions for the door and window. It was represented as an isolated structure away from its context.

Table 7. Reconstruction of Palestinian dwelling in Deir Aban Village.

Deir Aban village (1948-occupied Jerusalem)- General images of the Village

Images of inspiring houses and remains

3Ds of students' imaginations of the houses

Al-Qubeiba village (Table 8) inspiring houses seem to be more detailed and spacious than the previous villages. It is noticed that the student added a perception of the contemporary materials to feel time continuity for this house as it is still inhabited by its owners.

Table 8. Reconstruction of Palestinian Dwelling in Al-Qubeiba Village.

Al-Qubeiba village (1967--occupied Jerusalem)- General images of the village

 September 14-15, 2023, Naples, Italy

The images of Abu Dis village (Table 9) show clearly that the built environment of this village tends to be more transitioning towards civilization in that period (1967). The student perceived the sense of place of the inspiring house of this village in a similar way he perceived her contemporary built environment, so it is noticed that she added a wall in front of the doors of the house as a representation of property boundaries that used to be in civilian spaces.

Table 9. Reconstruction of Palestinian dwelling in Abu Dis Village.

Images of inspiring houses and remains

3Ds of students' imaginations of the houses

Nabi Samwil village (Table 10) shows the raised natural landscape of the village's terrains. The inspiring house shows a palace with several spaces and two stories. The student illustrated this unique architectural composition with its natural material and completed the living experience in this house by adding developed elements such as stairs and ironworks. However, the student also could not catch the full sense of place with its natural context.

4. CONCLUSION and RECOMMENDATIONS

It is concluded that even if the Palestinian students lost the ability to interact with their existential context where their real architecture emerged and developed, the phenomenological approach and cognition helped students catch some aspects of the villages and their dwellings.

Although it is noticed that the students could not represent the organic sense of place of natural landscape fully, it is considered very valuable to expose the students to such experience to build the conception of their architecture gradually.

In addition, The Palestinian sense of place and belonging is harmfully affected by the occupation. The ancestors belonging to the land feeling was altered in a dramatic way which affected the sense of being and the everyday lifeworld.

Furthermore, although the largest number of Palestinians are descendants of villagers, it is noticed that the new generation, including architecture students, have difficulties in simulation and living the lifeworld and experience of village life which is, in essence, the very original existential connection of the human to the earth.

Declaration of Conflicting Interests

The authors declared no potential conflicts of interest concerning the research, authorship, and/or publication of this article.

Note on Authors' Contribution

Dr. Abdurrahman Mohamed contributed 70% of the work and Architect Nesma El Saqqa contributed 30% of the work.

WALKABILITY IN URBAN DESIGN: THE CASE OF BURDUR-İSTASYON STREET

Assist. Prof. Dr. Ayşen Çoban (ORCID: 0000-0002-2512-2552)

Burdur Mehmet Akif Ersoy University, Faculty of Engineering and Architecture, Department of Landscape Architecture, Burdur-Türkiye

Email: acoban@mehmetakif.edu.tr

ABSTRACT

The concept of walkability revolves around the human experience within urban environments. It encompasses not just the presence of individuals on the streets but also their capacity to meet all their needs within a walking radius. The sprawling nature of cities, social and spatial segregation, reduced mobility, and environmental imbalances are among the challenges that non-walkable cities present. Addressing these issues, walkability strives to enhance the urban way of life by fostering a closer connection between people and their surroundings. The walkability of urban spaces stands as a pivotal concept for shaping habitable communities and fostering sustainable urban layouts, all attainable within a short walking distance. This study seeks to assess the quality of walkability in urban areas by considering specific walkability criteria. In this context, the research area chosen is Istasyon Street, a bustling thoroughfare in the heart of Burdur city, frequently utilized throughout the day. The walkability of Istasyon Street was meticulously scrutinized and evaluated based on predefined criteria such as scale, population density, accessibility, diversity, street quality, safety, and comfort. Drawing from the results, we've developed recommendations aimed at enhancing the walkability standards in Burdur's urban planning and design.

Keywords: Pedestrian, Walkability, Walkability Principles, Urban Design, Burdur.

1. INTRODUCTION

The 20th century stands out as the era in which human mobility was significantly amplified by the inventions of vehicles, fundamentally altering the way people move. The presence of automobiles has not only influenced the lifestyles of individuals but has also emerged as a transformative force, reshaping cities. This urban transformation relinquished control of streets to automobiles, resulting in streets being referred to as "roads." While under the dominion of automobiles, streets became hazardous for pedestrians, and city squares and open spaces transformed into parking lots (Ertuğrul, 2019).

The surge in mobility, primarily driven by motorized vehicles, gave birth to satellite cities on the outskirts of urban centers. These satellite cities that sprouted on the fringes of urban areas led to urban sprawl and expansion. In this process, city centers were perceived as business districts, while the satellite cities that flourished with the construction of highways were seen as residential areas (Ertuğrul, 2019). This phenomenon has accelerated the urbanization process, causing a decline in pedestrian movement, and, in some cases, its extinction. However, the emergence of vast expanses of asphalted open spaces allocated to roads and parking has resulted in environmental pollution, social and urban segregation, as well as health risks, among other perils (Rezaei, 2022). This underlines the necessity of embracing, once again, the urban lifestyle that was originally designed and planned within walking distance in the preceding century for the efficient utilization of urban space and areas.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

The concept of sustainable urbanization has brought about the idea of "livability" as an extension of urban quality of life, and livable cities have ushered in new urban paradigms (Gündoğdu & Dinçer, 2020). The concept of a "walkable city" is one of the fundamental principles of contemporary urban and transportation planning. A walkable city is one that has been designed or adapted to incorporate walkability into its urban structure, offering walking as a daily transportation option (Karımı, 2022).

One of the most significant tools that humans use to integrate with their environment is their ability to move. Through the act of moving within a space, individuals sequentially grasp and synthesize values related to their surroundings (Yazıcıoğlu Halu, 2010). One of the most fundamental activities people engage in to comprehend urban spaces is walking. Movement and accessibility within urban spaces are primarily achieved through the act of walking. In addition to serving as a means of transportation, walking also acts as a conduit for establishing an individual's connection with the city (Özalp, 2016). Those who do not walk within the built environment in which they live become detached from that environment, losing their connection with the "place." For such individuals, the walkability of the urban space becomes a crucial feature, as it plays a significant role in sustaining daily practices and the relationship between individuals and their social and physical environment (Ertuğrul, 2019).

Extensive research has delved into the concept of walkability, yielding various definitions. In this context, several of these definitions have been examined. According to Southworth (2005), walkability pertains to the capacity of the built environment to facilitate pedestrian access to specific destinations in a safe and comfortable manner, all while offering visually appealing surroundings that endorse and stimulate walking. Bosselmann (2008) situates walkability as an attribute of sustainable cities, encompassing social and natural ecology, personal safety, comfort, and access to amenities. Jacobs (2011) links walkability to the active use of streets, underlining that a vibrant urban life thrives when streets are in active use. Dover and Massengale (2013) define walkable streets as areas where *"residential, commercial, and institutional zones converge, where cyclists feel most at ease, and public transportation is most efficient, enabling face-to-face interactions, nurturing strong social bonds, and ensuring safety"* (Ertuğrul, 2019).

Medieval cities were remarkable due to their high walkability rates. These cities concentrated all urban necessities within a central square area, where everything was within a half-mile walk. For example, Urbino in Italy covered only 300 acres and housed 30,000 people (Southworth, 2005). The early American cities were also designed with high walkability in mind. Boston, Massachusetts, with its mixture of various districts, stands as a classic example. In the early 19th century, before extensive land reclamation, everything was located on a small peninsula just over 800 acres in size, and every point could be reached within a one-mile or half-hour walk. Despite significant growth and modernization, the central area of the city still maintains an exceptional level of walkability (Karımı, 2022). Copenhagen, despite retaining its medieval narrow and grid-patterned structure, serves as a good example of a pedestrian-friendly city. The city's main 2.3-kilometer artery, "Stroget," has been transformed into a pedestrian street, making it the world's longest pedestrian pathway. Through minor adjustments, urban planners have shifted the city away from car-centric focus to become pedestrian-friendly. As a result of these actions, the city's accessibility and walkability rates have increased (Bağcı, 2019). In Italian cities, life complements itself through environment, weather conditions, and architectural factors. Urban spaces, therefore, promote walking by fostering a high degree of

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

imaginability and a positive sense of place. In Galway, Ireland, people living in walkable neighborhoods know their neighbors and, as a result, trust each other more. This has turned them into a more social community, possessing social capital (Karımı, 2022).

The walking environment is considered a critical factor in creating a sustainable city because it contributes to the well-being of the city and its residents in areas such as health, social cohesion, safety, environment, and the economy. The specific contributions are outlined below:

Health (Ak, 2018; Bağcı, 2019; Ertuğrul, 2019; Mensi, 2021; Rhoads et al., 2023): In the past decade, a strong emphasis has been placed on walkability, primarily with the goal of improving public health. Walkability is viewed as a key factor in promoting health, as walking or cycling instead of driving has been shown to reduce the risk of heart disease, obesity, diabetes, and traffic-related injuries, according to Health Impact Assessment (HIA). The shock created by the COVID-19 pandemic in the past two years has underscored the importance of implementing "Open Streets" programs and has highlighted the significance of walkability in urban areas.

Social (Ak, 2018; Bağcı, 2019; Ertuğrul, 2019; Mensi, 2021; Velazquez et al., 2023): A city with extensive walkable areas fosters greater equality among different social classes, ethnic backgrounds, genders, and age groups. Such areas support and enhance social cohesion. Additionally, residents who walk to work or school and engage in daily activities by walking to local places and public spaces are more likely to lead active, healthier, happier, and sustainable lifestyles. Walkable spaces also strengthen social bonds among residents.

Environment (Bağcı, 2019; Mensi, 2021; Abastante et al., 2023; Velazquez et al., 2023): Urban mobility stands as one of the most effective solutions to the complex challenges cities face in sustainability and climate change resilience. Particularly, reducing car dependence can significantly mitigate its negative impacts on emissions, energy consumption, air and noise pollution. Walkability, by reducing dependency on fossil fuels used for transportation, can contribute to mitigating and adapting to climate change. Furthermore, designing walkable environments facilitates the construction of neighborhood or area-level green infrastructure features, including greenways, rain gardens, riverfront buffers, biological swales, permeable sidewalks, and green streets. This provides residents with more open space opportunities.

Safety (Bağcı, 2019; Mensi, 2021): One of the fundamental elements of walkability is creating a safe and healthy built environment through traffic design elements, traffic-calming measures, and vegetation to ensure real safety for the community. Moreover, walkability supports independence for individuals of all ages and abilities, contributing to a higher quality of life for everyone. When city residents feel safer, more people are encouraged to walk, which in turn enhances safety by preventing crime and improving public security.

Economy (Bağcı, 2019; Mensi, 2021): Recent research by the American Planning Association (APA) has demonstrated the positive impact of walkable environments on the economy. Similarly, Leinberger and Alfonzo (2012) categorized the economic benefits of walkability into four main areas: economic performance, effects of nearby walkable urban places, lower transportation costs, and social equity. More attractive walkable areas, vibrant social life, and active streets enhance commercial performance in the region. Walkability can also reduce expenses associated with car ownership. Residents who choose to walk to work or other nearby locations instead of using a car save on fuel costs, reduce transportation expenses, and improve access to public transportation.

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Gehl (2019) advocates for designing cities on a human scale, basing this approach on human capabilities and behaviors while emphasizing the significance of sensory organs. Consequently, the connection between physical form and human behavior becomes pivotal. Humans move on their feet, and the orientation of the human body is linear. Pedestrians walk faster on linear paths but slow down in plazas. The average walking speed in summer is 4.2 km/h, while in winter, it increases to 5.8 km/h. Although the walkable distance varies for pedestrians and is influenced by factors such as the elderly, people with disabilities, children, pavement quality, and the attractiveness of the route, a reasonable distance for many individuals is approximately 500 meters.

A reasonable walking distance of about 500 meters implies that city centers should also have a radius of 1 km. In a city with a 1 km radius, pedestrians can access most of the city's amenities by walking. The Chinese government argues that there should be 15-minute walkable neighborhoods to provide citizens with access to essential public services within a 15-minute walking distance, aiming to improve walking behavior and overall health. Figure 1 illustrates the types of amenities that should be located at 5, 10, and 15-minute distances within a 15-minute neighborhood (Şahin Deniz, 2022).

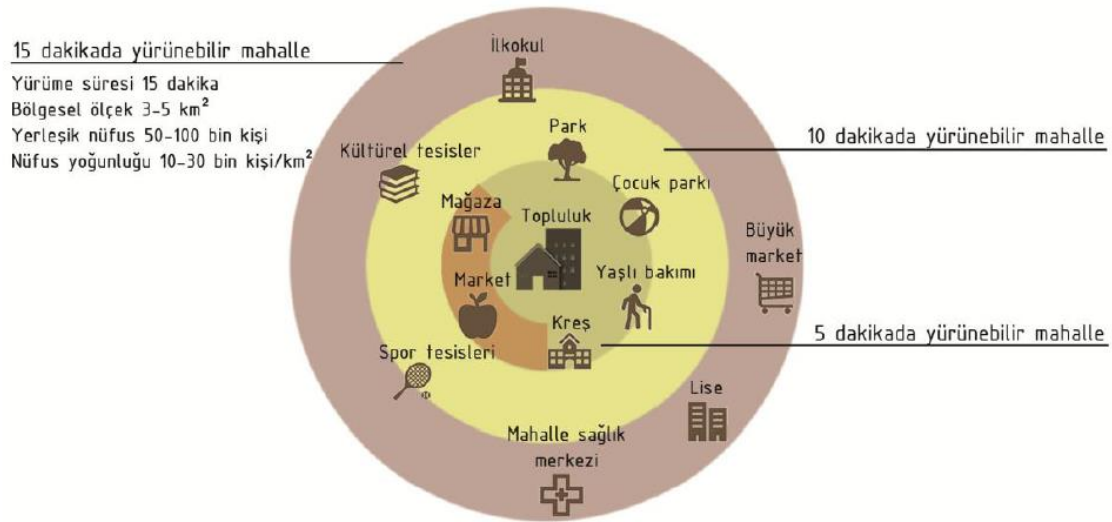

Figure 1. Uses within 5-10-15 minute distances in a walkable neighborhood.

Implementing regulations that promote physical activity in urban areas does not always suffice to encourage more people to walk. In this context, it is essential to understand which elements of the built environment primarily motivate individuals to walk. Scientific studies and research results highlight criteria that affect walkability, emphasizing features closely related to one another, such as scale, density, open spaces, accessibility, transportation systems, diversity, comfort, context, attractiveness, enclosure, legibility, transparency, street quality, and others. However, the relative importance of these identified criteria is still a subject of ongoing debate (Gündoğdu & Dinçer, 2020). In this regard, the evaluation, planning, and design of walkable cities should occur at various scales, including the city as a whole (macro), its subcomponents (meso), and individual streets (micro) (Ak, 2018).

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

In Türkiye, walkability gained significance, especially in the early 2000s, in the context of accessibility for people with disabilities. In recent years, within the framework of the Ministry of Health's "*Healthy Nutrition and Active Life Program in Türkiye (2013-2017)*," walkability has come to be viewed as a significant tool in promoting a healthy lifestyle and combating obesity. While these developments hold promise for the development of walkable and livable cities, the extent to which contemporary cities are effectively planned and designed for walkability remains a subject of discussion (Akkar Ercan & Belge, 2016).

This study aims to evaluate the quality of walkability in urban areas by taking into account specific criteria. For this purpose, İstasyon Street, situated in the bustling city center of Burdur and widely frequented throughout the day, was selected as the research area. The walkability of İstasyon Street has been assessed and appraised using criteria encompassing scale, density, accessibility, diversity, street quality, safety, and comfort. The findings have paved the way for crafting recommendations to improve the standards of walkability in the urban planning and design of Burdur.

2. MATERIALS and METHODS

Materials

The primary material for this study is İstasyon Street, located in the city center of Burdur, which is intensively used throughout the day.

Burdur is situated in the interior of the Mediterranean Region, in the region known as the "Göller Yöresi," at the transition point from the Mediterranean Region to the Aegean and Central Anatolia Regions. It is located between 29° 24' and 30° 53' east longitudes and 36° 53' and 37° 50' north latitudes. The province covers an area of 7,176 km², with an elevation of 950 meters. Burdur is surrounded by the following provinces: Antalya to the east and south, Denizli to the west, Muğla to the southwest, and Afyonkarahisar and Isparta to the north (Directorate of EIA and Environmental Permits, 2023). The population of Burdur province is 273,799, while the population of the city center is 193,185 (TURKSTAT, 2023).

İstasyon Street is located in the city center of Burdur, between the Burç and Konak neighborhoods. The reason for selecting İstasyon Street as the research area is its significance in terms of pedestrianization, or in other words, walkability, and its extensive use by the city's residents. The street has a length of approximately 425 meters. To the north of the research area line, there are İstasyon Park and Burdur Train Station, while to the south, there is Cumhuriyet Square. Along the street, there are residential areas, commercial establishments, government offices, and educational facilities (see Figure 2).

For the research area, the 1/1000 scale Burdur Implementation Zoning Plan was obtained from the Burdur Municipality, and Google Earth satellite images were utilized as the base. The criteria for assessing the walkability of İstasyon Street were incorporated into the base using the AutoCAD 2021 software.

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

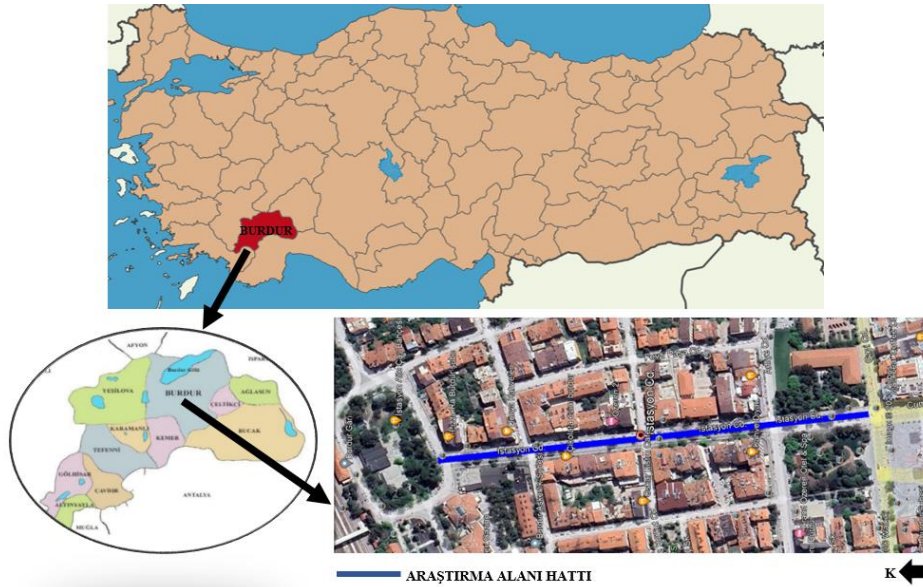

Figure 2. Research area location (accessed through Google Earth, 2023)

Methods

In the scope of this study, an initial literature review was conducted. Based on the information obtained from the literature review, criteria were established for evaluating the walkability of the research area. Building on the studies of Bağcı (2019), Ertuğrul (2019), Karımı (2022), and Şahin Deniz (2022), 7 criteria and their respective sub-criteria were identified (see Table 1).

Table 1. Walkability criteria and sub-criteria

Criteria	Sub-criteria
1. Scale	-
2. Density	-
3. Accessibility	3.1. Access to Public Transport 3.2. Parking Access 3.3. Access to Open and Green Areas 3.4. Barrier-Free Access
4. Diversity	-
5. Street Quality	5.1. Street Width 5.2. Street Signs 5.3. Street Furniture 5.4. Street Trees 5.5. Sidewalk Material 5.6. Sidewalk Width 5.7. Sidewalk Continuity 5.8. Street Maintenance
6. Security	-
7. Comfort	-

In the second stage, on-site observation was employed to assess the criteria influencing walkability. Photographs and videos of the area were taken. Furthermore, to determine pedestrian density, weekday and weekend pedestrian counts were conducted, with 10-minute

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

intervals on each of these days. The counts were conducted during three different time frames: 08:00-09:00, 12:00-13:00, and 17:00-18:00. Separate counts were made for those heading from the Station Park to Republic Square and those heading in the opposite direction.

In the final stage, recommendations for enhancing walkability quality in Burdur's urban planning and design were developed based on the data collected and analyzed.

FINDINGS and DISCUSSION

The criteria and sub-criteria listed in Table 1 were evaluated within the scope of the research area.

Scale

In urban space, factors such as street widths, sidewalk widths, building heights, block sizes, street furniture dimensions, road width, etc., influence the relationship of the scale with walkability. To create walkable environments, it is important that these qualities of urban space are at the human scale. Vertical dimensions up to two, three, or at most four floors are defined as the human scale. In other words, it is also defined as the floor height that can be reached without an elevator. Streets with a street width-to-building height ratio of one create an optimal walkable environment and spatiality (Figure 3) (Ertuğrul, 2019).

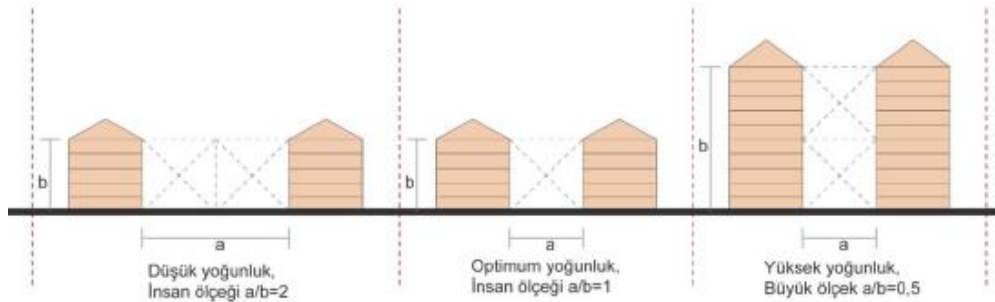

Figure 3. The ratio of street width to building height

If the building height is significantly greater than the width of the urban space, the human scale within the space disappears. The level of use in a space increases when the heights of buildings surrounding the environment are designed in proportion to the human body. Multi-story buildings break the human-building relationship by surpassing the human perception limit. Gehl (1978) notes that this relationship is particularly strong on the ground floor, diminishing as you go up to the third and fourth floors, and after the fifth floor, the sensory, visual, and social relationships are completely lost (Karımı, 2022).

In this context, when the building blocks on both streets in the study area are examined, it was determined that there are buildings with a minimum of 1 floor and a maximum of 5 floors (Figure 4). The average number of floors for both axes is 4. This situation indicates that the area is designed at a human scale. However, the scale determining factor in urban space is not only building heights. The ratio of street width to building heights should also be considered. The ratio of the street width in the study area to the building height is 1,75. Thus, it is determined that İstasyon Street creates a spacious spatial perception.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 4. Floor heights of the research area (Obtained from Burdur Municipality, 2023)

Density

Density measures the built environment or population in a specific area. In general, density is the ratio of the area occupied by buildings to the total land area or the ratio of people living or working within a specific area. Banz (1970) noted that human density reflects the density of use of the space (Ertuğrul, 2019).

To determine pedestrian density in the research area, the pedestrian crossing method used by Gündoğdu and Dinçer (2020) was employed. Within this method, pedestrian counts were conducted on two different days, namely, a weekend (September 3, 2023) and a weekday (September 7, 2023), in 10-minute intervals between 08:00-09:00, 12:00-13:00, and 17:00-18:00 in both directions (Cumhuriyet Square-İstasyon Park and İstasyon Park-Cumhuriyet Square) (Table 2).

Table 2. Pedestrian density within the research area

Time Periods	Weekend (03.09.2023)		Weekdays (07.09.2023)	
	Cumhuriyet Square-İstasyon Park Direction	İstasyon Park-Cumhuriyet Square Direction	Cumhuriyet Square -İstasyon Park Direction	İstasyon Park-Cumhuriyet Square Direction
08.00-09.00	19	23	33	26
12.00-13.00	36	41	66	83
17.00-18.00	164	137	255	235
Total	219	201	354	344

Due to the narrow street layout and pedestrianized nature of İstasyon Street, pedestrian use in this area is higher compared to other parts of the city. The research area is used by a total of 420 people on weekends and 698 people on weekdays. The peak hours for pedestrian traffic on both weekends and weekdays are between 17:00-18:00. İstasyon Street, in particular, is a frequented area for high school and university students. The reason for lower pedestrian density

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

on weekends is that residents of the city often travel to nearby cities such as Isparta and Antalya. However, it's worth noting that the pedestrian counts conducted using the crossing method on both weekends and weekdays occurred during periods when the university was not in session, minimizing the impact of university students on these calculations.

Accessibility

Pedestrian-friendly cities are those that prioritize high accessibility for pedestrians. Accessibility demonstrates how well pedestrians can navigate a city's streets and avenues. Pedestrian movement and accessibility are the ability for all groups, including the elderly and individuals with disabilities, to move safely and convincingly within all transportation systems (Southworth, 2005). This criterion, as in the study conducted by Bağcı (2019), is examined through four sub-criteria: access to public transportation, access to parking, access to open and green spaces, and barrier-free access (Figure 5).

Figure 5. Accessibility analysis of the research area (Obtained from Burdur Municipality, 2023)

Access to Public Transport

Southworth (2005) has mentioned that in a larger city and region, access to reasonable distance and likely connections to other nodes will be provided. Therefore, an acceptable distance to transportation stations should be 400 to 800 meters or a 10-20 minute walking distance. This requirement enhances the walkability of the environment.

There are no public transportation stations within the defined research area. However, the bus stop located just outside the research area (two bus stops across from each other on Namık Kemal Avenue) can be reached in approximately 3 minutes (Figure 5, Figure 6). There is no taxi stand within the research area, and access can be achieved by private vehicle.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 6. Bus stops on Namık Kemal Street

Access to Parking

Parking is one of the significant elements of street design that can influence pedestrian behavior both positively and negatively. While it has become a focal point for access to public transportation, access to parking is still perceived as a necessity in traditional settlements, new developments, and public spaces. Zuniga-Teran et al. (2017) have pointed out that the fewer parking spaces are provided on streets, the more walkable they become, encouraging people to engage in physical activity through alternative transportation methods (Bağcı, 2019).

There are no public or covered parking facilities available for users and local residents within the research area. High pedestrian traffic and traffic congestion are observed in the area due to the lively commercial uses. Furthermore, users and local residents park their vehicles on the streets, which leads to narrowing road width and parking issues. Moreover, parking vehicles on the street restrict pedestrian and vehicular movements (Figure 5, Figure 7).

Figure 7. Vehicles parked on Station Street

Access to Open and Green -Spaces

In urban areas and neighborhoods, access to open and green spaces can be defined by the presence, size, proximity, and ease of access to vegetated areas. Streets should provide permeable pathways or access, be designed without physical barriers, offer convenience, and be accessible to the landscape. When examining urban plans, it is evident that green spaces play

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

a crucial role in enhancing the quality of life and the city. There should be a small green area (2 hectares) within a 400 m walking distance (Bağcı, 2019).

Within the research area (in the direction from İstasyon Park to Cumhuriyet Square), there is one park located across from Cumhuriyet Square. This park is named Cumhuriyet Square Park. Due to its location, it is one of the most frequently used and bustling areas. The park serves as a gathering and resting point for city residents and is also where events at Cumhuriyet Square are observed. For a pedestrian entering from İstasyon Parkı, this park is approximately 375 meters away (Figure 5, Figure 8).

Figure 8. Cumhuriyet Square Park

Barrier-Free Access

Public spaces hosting various activities are important urban areas that facilitate communication and interaction among people. In order for individuals with disabilities to have equal rights and lead an inclusive life while participating in social activities, urban public spaces must be designed according to accessibility standards (Bağcı, 2019).

Based on direct observations, it is noted that there are ramps, guide paths, and wheelchair charging stations for wheelchair users on both sides of İstasyon Street to promote barrier-free access. The widths of the sidewalks on both the right and left sides in the direction from İstasyon Park to Cumhuriyet Square are found to be appropriate. However, on the left side, in the vicinity of the trees, contrasting grating or gravel that aids visually impaired individuals has not been used (Figure 9).

September 14-15, 2023, Naples, Italy

Figure 9. Examples of barrier-free access on Station Street

Diversity

Urban diversity is one of the most critical factors for vibrant street life. Urban diversity involves the integration of various functions within the built environment. The arrangements in the built environment influence the use of space and relationships among users. Preserving structures, landscape elements, streets, or names that have witnessed significant events or hold historical or emotional value for people is of utmost importance in maintaining urban diversity. The coexistence of structures from different eras is indicative of the visual diversity of a city (Bağcı, 2019; Ertuğrul, 2019; Karımı, 2022).

Aggregating commercial spaces selling similar products singularizes the functional use of that region. These types of spaces should be evenly distributed throughout the region, ensuring more equitable access for all city dwellers and stimulating commerce. Additionally, residents in an area should be able to meet all their needs within their own neighborhoods. For this purpose, each part of the city should host spaces catering to various needs such as housing, commerce, recreational activities, social interactions, and entertainment. Only through such an approach can compact city sections with diverse functions be created, eliminating the need for city residents to travel extensive distances between their homes and workplaces. Shaping urban spaces functionally in this manner ensures the development of livable city sections within walking distance (Bağcı, 2019; Ertuğrul, 2019; Karımı, 2022).

In the study area, in addition to spaces dedicated to essential functions such as commerce, residential areas, and shopping, the inclusion of areas designed for cultural, social, and recreational activities provides city inhabitants with the means to satisfy a broad spectrum of requirements. The variety found within the area caters to fundamental, choice-driven, social, and leisure needs, thereby fostering the development of a walkable and enjoyable space in close proximity. The area's diversity was assessed by taking into account the functional purposes incorporated within the structural blocks on both sides of the street (Figure 10).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 10. Regions where the diversity of the research area is evaluated (Obtained from Burdur Municipality, 2023)

In Area A, there are a total of 11 buildings, each featuring 22 distinct commercial establishments (including markets, cafes, restaurants, retail shops, pharmacies, etc.) situated on the ground floor. In Area B, there are a total of 12 buildings, with 24 diverse commercial enterprises (such as markets, cafes, restaurants, retail outlets, pharmacies, etc.) occupying the ground floor. The data indicates that multiple types of commercial enterprises coexist within each building (Table 3).

Table 3. Research area diversity

Diversity	Region A	Region B
Health Unit	-	1
Pharmacy	1	2
Beauty Center	-	1
Gym	1	1
Educational Facility	-	2
Housing	-	2
Market	3	1
Cafe / Restaurant	13	7
Market for Pets	1	1
Trade	2	3
Vacant	1	3
Total	22	24

Street Quality

Streets have been pivotal public spaces since the advent of social life, where public interaction, sharing, transportation, and mobility emerged. Therefore, in order to enhance walkability and

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

public sharing, streets need to be functionally and aesthetically organized for everyone. In other words, streets should be arranged with quality, sustainable management, and a healthy urban perspective (Bağcı, 2019). In this context, street quality is assessed through sub-criteria, including street width, street signage, street furniture, street trees, pavement materials, pavement width, pavement continuity, and street maintenance.

Street Width

Pedestrian pathways should be separated from roadways on streets, and bike lanes should be included. In some cases, restricting access to the frontage may be necessary, and parking on the street may be allowed, or, in other situations where traffic is heavy, street parking should be discouraged (Bağcı, 2019).

Within İstasyon Street, pedestrian pathways and roadways are separated, but no provision has been made for bike lanes (Figure 11).

Figure 11. A sign in the research area where bicycle entry is prohibited

In the study area, the street's width is approximately 21 m, with a road width of around 6.40 m (Figure 12). Furthermore, parking vehicles on the street leads to traffic congestion.

Figure 12. Research area street width

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Street Signs

Incoherent signage that creates visual clutter and confusion plays a pivotal role in shaping the perception of a city. According to Lynch (1960), a city should be both legible and recognizable. Urban design, in this regard, emerges as a paramount determinant of urban identity. Through the elements of urban design, an entire street in the city can be transformed into a harmonious, novel, aesthetically pleasing space that resonates with the city's culture and identity. For instance, in a study conducted in Türkiye, street arrangements, the colors of commercial signage, signs affixed to facades and sidewalks/pedestrian walkways, exhibitions, tables, and chairs were tested using virtual environments. The findings revealed that streets with monochromatic signs were deemed more suitable and were preferred for shopping compared to streets with polychromatic signage (Bağcı, 2019).

Within the research area, there are various ground-level uses. Each establishment employs signs to convey information about these uses and guide city residents to their respective locations. However, well-designed and harmonious signs are conspicuously absent. There is no shared visual language, and advertising billboards substantially diminish the ambiance of the space (Figure 13).

Figure 13. Street signs within the research area

Urban Furniture

Urban furniture encompasses objects within the urban landscape that serve to ease individual and social life, facilitate interpersonal interactions, bestow functionality and aesthetics upon space, and come in various qualitative and quantitative forms. Furthermore, urban furniture carries cultural and social significance in the daily routines of urban life, contributing to the city's identity (Bağcı, 2019).

Through direct street-level observations, it is evident that street furniture, notably waste bins, benches, and lighting fixtures, has been thoughtfully arranged. Signs of vandalism are apparent on recycling bins, clothing and shoe collection bins, and other pieces of furniture, which detrimentally affect the overall quality of the street. Additionally, İstasyon Street boasts sculptures that invigorate the ambiance of the space and have become integral components of the city's identity (Figure 14).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Figure 14. Street furniture within the research area

Street Trees

Street trees play a vital role in urban centers by improving the quality of life, enhancing the city's visual appeal, bolstering ecological characteristics, reducing carbon dioxide emissions, and carbon sequestration. However, it is imperative that street trees do not impede pedestrian crossings, visibility, or road and street utilization (Bağcı, 2019).

As you progress towards Cumhuriyet Square from İstasyon Parkı, you'll encounter *Pinus brutia* gracing the central median within the research area, accompanied by *Lavandula angustifolia*. This central median, extending from the Burdur Governor's Bulfind to Cumhuriyet Square Park, maintains its *Pinus brutia* presence, with *Rosa* sp. beneath. Along the same path, the right

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

side of the median features Rosa sp. in the parterre. At intervals along the right side, one can spot various tree species like *Fraxinus excelsior* and *Tilia cordata*. On the left side (following the roadway), different tree species such as *Fraxinus excelsior*, *Tilia cordata*, and *Jacaranda mimosifolia* have been thoughtfully planted. Notably, the plant selection for İstasyon Street did not fully incorporate design elements and principles (Figure 15). It's important to emphasize that the chosen plantings within the research area do not obstruct pedestrian access.

Figure 15. View of street trees within the research area

Sidewalk Material

A sustainable and robust sidewalk is one that's thoughtfully designed to integrate seamlessly with the local environment. When it comes to pedestrian spaces, the priority lies in selecting materials known for their durability, surface evenness, and resistance to slipping. These materials should be resilient, ensure safety, and allow for easy replacement when needed (Bağcı, 2019). In the research area, both sidewalks providing pedestrian access are crafted using basalt and andesite cobblestones. It's noteworthy that these sidewalk materials show no signs of deformation. However, during periods of heavy rainfall, the surface may become slippery, presenting certain challenges (Figure 16).

Figure 16. Materials and pavement dimensions used in pavement in the research area

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Sidewalk Width

The width of sidewalks is determined based on factors such as their urban location, the population they serve, land usage, and user density. For instance, in city centers where a variety of functions coexist, sidewalks tend to be wider due to their functional appeal and the high volume of pedestrian traffic attracted by transportation hubs. According to the "*Urban Roads - Design Criteria for Preventive Barriers on Sidewalks (2012)*" guide published by the Turkish Standards Institute (TSE), the minimum pedestrian width should be 1,50 meters. Furthermore, this guide specifies ideal sidewalk widths. These are (Bağcı, 2019):

- In cases where pedestrian sidewalks are not needed, shoulders ranging from 0.75 to 2 meters in width should be provided. For district connections, regional collector roads, inner and service roads on highways, pedestrian walkways at least 2 meters wide should be established on both sides of the road.
- On roads without front gardens, the pedestrian sidewalk should be at least 2.50 meters wide. In areas with heavy pedestrian traffic, like commercial districts, office areas, public buildings, and central business districts, the sidewalk's width should be a minimum of 5 meters.
- If the road width is insufficient, sidewalk width can be reduced to as little as 3 meters. However, in new road arrangements in residential areas designated for urban development, the sidewalk's width should not fall below 1 meter.

Within this context, the widths of sidewalks in the research area adequately accommodate pedestrian traffic (Figure 16).

Sidewalk Continuity

In pedestrian sidewalk design, the fundamental principle is to ensure the safety and comfort of pedestrians while, at the same time, providing the shortest path from one point to another to maintain the continuity of the street. Sidewalks should not contain any obstacles (such as obstructions, advertising billboards, utility poles, garbage containers, vehicles, store merchandise, etc.) that impede pedestrian movement and/or jeopardize their safety (Bağcı, 2019).

Within the research area, sidewalk continuity is often preserved. However, sidewalks separated by side streets are sometimes obstructed by parked vehicles at their starting or ending points. Moreover, despite the prohibition of motor vehicle entry into the area, these vehicles are still used, disrupting sidewalk continuity.

Street Maintenance

The preservation and maintenance of urban furniture and infrastructure elements in public spaces are essential for ensuring the continuity of the quality of life and the pedestrian network. In urban spaces, the sustainability of social activities and user satisfaction is only possible in a healthy and clean environment. Ensuring good health conditions for all urban residents, maintaining their continuity, and taking preventive measures in situations that threaten public health are crucial in considering the importance of environmental health in urban areas (Bağcı, 2019). Within this context, the study area provides a clean environment for users. However, inscriptions and deformed appearances on street furniture have a negative impact on street maintenance.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Safety

The continuous visibility of the street, the absence of high-walled structures in the area, and well-lit streets are some of the characteristics that make the area secure. From a traffic safety perspective, there is a more extensive sidewalk area where pedestrians can walk safely.

The parked vehicles surrounding the traffic do not generally threaten the safety of pedestrians, but vehicles, in general, dominate a significant portion of the street. In addition, moving vehicles are considered safe as they cannot travel at high speeds. To enhance this safety, speed bumps are also present on the roads. Crosswalks are available to ensure pedestrians can safely cross from one side to the other.

Another contributing factor to the region's safety is that many establishments in the study area remain open late into the night, and residents are often out on the streets until the late hours. Street lighting within the area contributes to increased security (Figure 17).

Figure 17. Evening lighting view from the research area

Comfort

The sidewalk widths that promote pedestrian comfort and encourage walking are consistent on both sides of the street, providing city residents with a comfortable walking experience. As depicted in Figure 17, the sidewalk on the left side is suitable for group walking.

The street trees lining the street create a scenic effect throughout the area. The evening and nighttime lighting of the area ensures that the space is comfortably usable.

3. CONCLUSION and RECOMMENDATIONS

This study delves into the significance of walkability in human life and its critical role in shaping livable environments, examining various criteria that influence walkability. These criteria encompass factors like scale, population density, accessibility, diversity, street quality, safety, and comfort.

What we observe is that urban dwellers tend to gravitate towards areas where these criteria are reasonably met, consequently fostering the development of more livable urban landscapes. Maintaining a human-scale environment allows city residents to navigate the streets more efficiently, while diversity promotes the presence of various groups throughout the day, ultimately enhancing both the usage and safety of these streets. Moreover, there exists a strong

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

correlation between the diversity of functions, space utilization, and pedestrian density. Safety within the area extends its usability into late hours. Enhancing accessibility contributes to denser usage. Establishing the requisite comfort conditions encourages city residents to stroll through the streets at a more leisurely pace, facilitating their assimilation into the urban space. Elements such as urban furniture play a role in fostering socialization among residents. In addition, it is crucial that urban furniture in each city is designed and manufactured in harmony with the city's unique identity. The establishment of a coordinating commission for urban furniture among existing elements can help create a shared design language. Vandalism affecting street furniture has repercussions not only on street quality but also on safety considerations. Therefore, campaigns to raise awareness are essential. Given that all the criteria mentioned are interconnected, achieving their optimal balance is paramount. The specific levels of optimization vary depending on the location, social structure, and space.

In contemporary cities, it is impractical to traverse the entire urban landscape solely on foot. Consequently, cities should prioritize walkability at the local level while also providing macro-scale pedestrian-focused alternative transportation systems for accessibility. In the specific context of Burdur, emphasis should be placed on pedestrian-oriented transportation systems. Transportation plans should be developed or revised accordingly, ensuring that the city and its residents have increased access to pedestrian-friendly areas. In this context, the inclusion of Gazi Street as a pedestrian-focused zone in alignment with the research area is recommended.

ABSTRACT

Natural processes such as earthquakes, floods, erosion, landslides, and hurricanes have always occurred and will always occur since the world has existed. These natural processes turn into natural disasters by causing loss of life and property due to reasons such as the incompatibility of human versatile activities with natural processes, damaging approaches, and not taking necessary precautions. In particular. Since our country is located in an earthquake zone and it is not known where, when, what magnitude, how, and what type of earthquakes will occur, it is a vital necessity to take necessary measures within the scope of risk and crisis management to minimize possible material and moral damages. In Türkiye, disaster management is managed by (AFAD). Municipalities have assumed only a support role. However, due to the centralized structure experienced in the disasters, the role or intervention effect of local administrations has been reduced especially in the first critical moments of the disaster phase and afterward, the coordination between the center and local bodies and NGOs has not been established. The purpose of "Disaster and Risk Management" is to ensure that the technical, administrative, and legal works required are carried out by both central and local administrations and all public institutions and organizations together with non-governmental organizations with the participation of the public to ensure that rapid and effective rescue, first aid, temporary sheltering and reconstruction activities are carried out during and after the disaster with the measures to be taken before the disaster to prevent disasters in settlements, to be prepared against disasters and to reduce their damages are carried out within a system. While providing disaster and risk management, local administrations should be at the center of this work by the concept of subsidiarity. Because municipalities are one of the leading partners of the efforts aiming to be resilient against disasters. The role of municipalities in risk and crisis management and organization is of great importance in ensuring the safety and well-being of communities affected by disasters. In this context, it is responsible for minimizing the impact of disasters such as earthquakes, responding quickly, providing recovery efforts, and building resilience to prevent or mitigate future disasters. In this study, the roles, duties, and responsibilities of municipalities in risk and crisis management before, during, and after earthquake disasters are revealed, current problems are revealed with SWOT analysis under 3 main headings, and suggestions are made by making evaluations.

Keywords: Earthquake, Disaster, Risk and Crisis Management, Municipalities, Local Governments.

September 14-15, 2023, Naples, Italy

1. INTRODUCTION

Natural processes such as earthquakes, floods, erosion, landslides, and hurricanes have always occurred and will always occur. According to the United Nations, half of humanity now lives in cities. The urban population has been exceeding the rural population since 2008 and this rate is expected to be around 70% in the 2050s (Albrito, 2012).

These natural processes turn into natural disasters by causing loss of life and property due to reasons such as human multifaceted activities not being compatible with natural processes, having damaging approaches, and not taking necessary measures. As a result, natural disasters are a human-induced result.

The turning point in the field of disaster management and coordination in Türkiye was the Marmara Earthquake of August 17, 1999. This earthquake, which caused great loss of life and extensive damage, painfully demonstrated the necessity of revisiting the issue of disaster management in Türkiye. Accordingly, the General Directorate of Civil Defense under the Ministry of Interior, the General Directorate of Disaster Affairs under the Ministry of Public Works and Settlement, and the General Directorate of Emergency Management of Türkiye under the Prime Ministry were closed down and the "Disaster and Emergency Management Presidency" under the Prime Ministry was established with the Law No. 5902 enacted in 2009 and the authorities and responsibilities were gathered under a single roof. The Presidency was affiliated with the Ministry of Interior with Presidential Decree No. 4 published on July 15, 2018. The Disaster and Emergency Management Presidency continues to operate as a flexible and dynamic institution that ensures cooperation among all institutions and organizations of the country to plan, direct, support, coordinate, and effectively implement the activities required for the prevention of disasters and mitigation of their damages, response to disasters and rapid completion of post-disaster recovery efforts. In this framework; a new disaster management model has been put into practice in Türkiye and with this model, priority has been given from "Crisis Management" to "Risk Management". This model, which is nowadays called an "Integrated Disaster Management System", envisages the identification of hazards and risks in advance to prevent the damages caused by disasters and emergencies, taking measures to prevent or minimize the damages that may occur before the disaster occurs, ensuring effective response and coordination, and carrying out post-disaster recovery works in integrity (AFAD, 2018).

The aim of "Disaster and Risk Management" is to ensure that the technical, managerial, and legal works required to be carried out by both central and local administrations and all public institutions and organizations together with non-governmental organizations are carried out within a system with the participation of the public to ensure that rapid and effective rescue, first aid, temporary sheltering, and reconstruction activities are carried out during and after the disaster with the measures to be taken before the disaster to prevent disasters in settlements, to be prepared against disasters and to reduce their damages.

Disaster management in Türkiye is managed by the central administration "AFAD". Municipalities have assumed only a support role. However, the centralized structure experienced in disasters has reduced the role or intervention impact of local governments and led to a lack of coordination between the center and local bodies and NGOs, especially during and after the first critical moments of the disaster phase. One of the most painful examples of this is the regional earthquake disaster centered in Kahramanmaraş on February 6, 2023. The

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

February 6 earthquake disaster has shown how vital it is to implement holistic strategic actions in the short and long term, before, during, and after the earthquake process. However, the regional earthquake disrupted the first response and disaster management due to the centralized structure and produced undesirable results.

While providing disaster and risk management, local administrations should be at the center of this work following the concept of subsidiarity. This is because municipalities are one of the leading partners in efforts aimed at disaster resilience. The role of municipalities in risk and crisis management and organization is crucial in ensuring the safety and well-being of communities affected by disasters. In this context, they are responsible for minimizing the impact of disasters such as earthquakes, responding quickly, providing recovery efforts, and building resilience to prevent or mitigate future disasters.

Municipalities have been assigned certain duties and responsibilities under both Article 7 of Metropolitan Municipality Law No. 5216 and Article 53 of Municipal Law No. 5393. However, these are not at a sufficient level. Besides, the fact that some of the metropolitan municipalities, non-metropolitan provincial municipalities, and district and town municipalities do not have units or directorates related to disaster management constitutes a major problem.

In this study, the roles, duties, and responsibilities of municipalities in risk and crisis management for natural disasters under 3 main headings: Pre-disaster phase (Preparation), Disaster phase (Confrontation), and Post-disaster phase (Recovery) have been examined and solutions have been proposed.

2. MATERIALS and METHODS

Examining the existing legislation related to municipalities and issues related to natural disasters have been identified and analyzed. In addition, a SWOT analysis was made to determine the current situation in municipalities for natural disasters. Service units in the management organization in municipalities were defined. Duties and responsibilities that municipalities should undertake in 3 dimensions pre-disaster, during, and post-disaster are proposed.

3. RESULTS and DISCUSSION

3.1. Local Government and Municipalities:

Municipalities, the most well-known local government unit by citizens (Bayrakçı, 2018, p. 305), date back to the 1800s (Ottoman Empire). Municipalities are regulated in their latest form in the Municipality Law dated 03.07.2005 and numbered 5393. Municipal Law No. 5393 defines a municipality (Art.3/a) as "a public legal entity with administrative and financial autonomy, established to meet the local common needs of the residents of the municipality and whose decision-making bodies are elected by the electorate" (Belediye Kanunu. 2005).

Municipalities are public legal entities in charge of meeting the common needs of the local population. They are the institutions where services can be provided in the most effective, rational, and fastest way (Urhan, 2008).

Article 14 of the Municipality Law No. 5393 stipulates the duties and responsibilities of the Municipality; (Belediye Kanunu, 2005).

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

a) *"Provided that it is of a local common nature, the Municipality shall provide or have provided: urban infrastructure such as zoning, water and sewerage, transportation; geographical and urban information systems; environmental and environmental health, cleaning and solid waste; zoning, fire brigade, emergency aid, rescue and ambulance; urban traffic; burial and cemeteries; afforestation, parks and green areas; housing; culture and arts, tourism and promotion, youth and sports secondary and higher education student dormitories, social services and assistance, marriage, vocational and skill acquisition; development of economy and trade services."* (Belediye Kanunu No. 5393, 2005).

There are five types of municipalities in Türkiye: metropolitan municipalities, provincial municipalities, metropolitan district municipalities, district municipalities, and town municipalities. According to the official website of the Ministry of Interior, there are 30 metropolitan municipalities and 51 provincial municipalities in Türkiye.

3.2. The Current Situation and Examination of the Duties and Responsibilities of Municipalities Regarding Natural Disasters in the Existing Legislation in Our Country

The duties and responsibilities of municipalities in the face of earthquake disasters are specified below in Metropolitan Municipality Law No. 5216 and Municipality Law No. 5393.

Article 7 (Duties, Authorities, and Responsibilities of the Metropolitan Municipality) of the Metropolitan Municipality Law No. 5216 (Official Gazette Date: 23/7/2004, Issue: 25531). (Büyükşehir Belediyesi Kanunu, 2004).

u) By the plans made at the provincial level, to make plans and other preparations for natural disasters at the metropolitan scale; to support other disaster areas with tools, equipment and materials when necessary; to carry out fire brigade and emergency aid services; to identify places of production and storage of explosives and flammable substances, to inspect residences, workplaces, entertainment places, factories and industrial establishments and public institutions in terms of measures to be taken against fire and other disasters, and to issue permits and licenses required by the legislation in this regard,

z) Providing all kinds of support upon request of district municipalities for the evacuation and demolition of buildings at risk of disaster or posing a danger to life and property.

Article 53 (Emergency Planning) of the Municipal Law No. 5393 (Date of Publication in the Official Gazette: 13/7/2005 Number: 25874) (Belediye Kanunu. 2005).

o The municipality shall make the necessary disaster and emergency plans and prepare the necessary teams and equipment, taking into account the characteristics of the municipality, to protect against fire, industrial accidents, earthquakes, and other natural disasters or to reduce their damages.

o In the preparation of emergency plans, coordination shall be ensured with other emergency plans at the provincial scale, if any, and the opinions of relevant ministries, public institutions, professional organizations, universities, and other local administrations shall be taken.

o In line with the plans, necessary measures shall be taken for public education and joint programs may be carried out with the administrations, institutions, and organizations listed in the second paragraph.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

o In case of fire and natural disasters outside the boundaries of the municipality, the municipality may provide necessary assistance and support to these regions.

Under the heading of land and housing production, Article 69; (Belediye Kanunu. 2005).

..... land can be allocated to those exposed to disasters, to those who will be transferred from industrial zones, and to cooperatives whose members are all in this situation, at an amount not less than the amount to be determined by the appraisal commission established by the provisions of the Expropriation Law No. 2942.

Regarding Urban Transformation and Development Area Article 73- (Amended: 17/6/2010-5998/1 Art.): (Belediye Kanunu. 2005).

Municipalities may implement urban transformation and development projects with the decision of the municipal council to create housing areas, industrial areas, commercial areas, technology parks, public service areas, recreation areas, and all kinds of social reinforcement areas, to rebuild and restore the old parts of the city, to protect the historical and cultural texture of the city or to take measures against earthquake risk.

3.3. Management Organization and Service Units in Municipalities

Municipalities try to carry out their services and activities within the framework of the legislation under different units within the framework of management organization. The names and number of units in the municipal administration may vary according to the population and needs.

- Department of Building Control: It carries out duties related to the inspection, correspondence, works, and transactions related to all existing structures, burned and demolished structures, licensed constructions, structures contrary to the license, and annexes within the municipality borders (Ercan, 2017).

- Department of Public Works: It carries out all kinds of construction works planned by the municipality, as well as the opening, construction, and repair of roads within the municipality's jurisdiction. In addition, all kinds of demolition works carried out by the municipality are also carried out by this directorate (İstanbul Büyükşehir Belediyesi (İBB), 2023; Belediye Kanunu, 2005).

- Department of Zoning and Urbanization: By the relevant laws and regulations of these laws, this department supervises zoning activities within the boundaries of the municipality, issues building permits and occupancy permits, gives opinions of conformity regarding construction and building height, in short, performs all duties related to zoning (İBB, 2023; Belediye Kanunu, 2005).

- Department of Parks, Gardens, and Green Areas: One of the main duties of the Department is to develop and supervise projects for playgrounds, gardens, pedestrian paths, and green areas within the boundaries of the municipality (İBB, 2023; Belediye Kanunu, 2005).

- Department of Cultural Heritage: One of its main duties is to prepare/ have prepared urban design projects for immovable cultural assets, protected areas, and historical environments that need to be protected, and to supervise surveying and restoration works (İBB, 2023).

TeMALab
 Department of Civil, Building and Environmental Engineering
 University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

- Department of Earthquake Risk Management and Urban Improvement: Its task is to identify disaster risks within the municipality boundaries, create hazard maps, and develop/implement plans and projects to reduce earthquake risk (IBB, 2023; Belediye Kanunu, 2005).
- Rail System Department: To make/make the rail system routes, the necessary project, the materials to be used, the necessary modification works, in short, every detail related to the rail system, and to inspect and control all of these (IBB, 2023).
- Department of Real Estate Management: The operations and management of the immovable properties that the municipality needs or owns are carried out (IBB, 2023).
- Department of Support Services: Its task is to maintain and repair all buildings and facilities owned or used by the municipality (IBB, 2023; Belediye Kanunu, 2005).
- Department of Studies and Projects: Evaluates and examines infrastructure, superstructure, and urban design projects, and prepares the project if deemed appropriate. Works in coordination with other units (IBB, 2023).

In the study conducted by Özdemir in 2023, "The corporate websites of metropolitan and provincial municipalities in 81 provinces were examined and their existing units related to disasters were investigated. Among 30 metropolitan municipalities, 22 of them have disaster-related units while 8 of them do not have any disaster-related units. It is seen that 7 of the metropolitan municipalities have Departments of Earthquake Risk Management and Urban Improvement. It is determined that 17 of the metropolitan municipalities have Disaster Coordination Center (AKOM) units.

In 51 provincial municipalities that do not have metropolitan status, there is no unit for disaster services. In some municipalities, disaster management services are tried to be carried out through civil defense experts or civil defense units. There is no AKOM in provincial municipalities. It has been determined that very few district municipalities have established AKOMs and carry out activities for disaster services.

4. RESULTS and DISCUSSION

4.1. SWOT Analysis and Analysis of Municipalities for Disaster Management

SWOT analysis of municipalities on issues such as building inspection and retrofitting, zoning practices, legal studies, financial resource studies, training studies, social activities, and disaster and risk management strategies were conducted.

Table 1. SWOT analysis to determine the current situation regarding natural disasters in municipalities

Strengths	<ul style="list-style-type: none"> • 22 of the 30 metropolitan municipalities have disaster-related units, • 17 of the Metropolitan Municipalities have a Disaster Coordination Center (AKOM) unit, • Presence of Departments of Earthquake Risk Management and Urban Improvement in 7 of the metropolitan municipalities, • Municipalities have the infrastructure to create temporary shelter areas after disasters, • Municipalities have sufficient knowledge and experience in natural disasters.
------------------	---

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Weakness

- Article 7 of the Metropolitan Municipality Law No. 5216 and Article 53 of the Municipality Law No. 5393 do not detail the powers and responsibilities given to municipalities,
- Lack of a strategic management approach and vision for natural disasters in municipal administrators,
- Only 7 of the metropolitan municipalities have Departments of Earthquake Risk Management and Urban Improvement,
- 51 provincial municipalities without metropolitan status do not have any unit for disaster services,
- Lack of a Disaster Coordination Center (AKOM) in provincial municipalities,
- Failure to establish Disaster Coordination Centers (AKOM) in district municipalities and inadequate work on disaster services,
- Among the 30 metropolitan municipalities, 8 of them do not have disaster-related units,
- Lack of local earthquake master plans,
- Failure to reflect the holistic decision-making process for natural disasters in urban development plans,
- Lack of educational activities in municipalities to raise awareness of urban people about natural disasters,
- Inadequate number of technical and auxiliary personnel, tools, and equipment capacity in the approval, inspection, and control processes of construction projects in municipalities,
- Although it is compulsory in municipalities, the Urban Information System is still not established or activated,
- Ineffective use of geographical information systems,
- Urban green space planning and organization is not handled holistically,
- Lack of adequate areal size and multi-purpose functionality of green areas at urban and neighborhood scale and lack of association with natural disasters,
- Lack of or insufficient joint work and cooperation with voluntary institutions and organizations such as the City Council and NGOs on Natural Disasters,
- Lack of strong technological infrastructure,
- Lack of coordination and communication between units within the Municipality,
- Inadequate performance monitoring and evaluation system in municipalities,
- Inadequate drills on natural disasters within the municipality,
- Lack of development of warning-warning systems, etc.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Opportunities	<ul style="list-style-type: none"> • Municipalities' local facilities are easier to use at every stage of the earthquake disaster, • The ability of municipalities to identify temporary shelter and gathering areas when making development plans, • Voluntary communities such as city councils, NGOs, student clubs, • The existence and experience of AFAD and experienced NGOs.
Threats	<ul style="list-style-type: none"> • Municipalities do not take into account the geological-geotechnical ground surveys for the zoning plan during the construction of the zoning plans, and therefore, the earthquake disaster, • Earthquake risks are everywhere in Türkiye. • A high economic profit (rent) system is widespread in the construction sector and ethical values are gradually weakening, • Inadequate holistic supervision and control mechanisms in state institutions and organizations.

4.2. General Framework of Duties and Responsibilities of Municipalities in Natural Disaster Risk and Crisis Management

It is not possible to predict and prevent earthquake disasters and many other disasters. For this reason, rather than preventing earthquake disaster, measures can be taken in three stages pre-disaster, disaster moment, and post-disaster to warn, warn, and reduce the physical, social, and economic losses it will cause after the disaster (Geray, 1977).

According to Solway (2004), the role of local governments in natural disaster management should be as follows; a. Identify vulnerable people and areas in the region b. Ensure that all members of the community are aware of the potential impacts of natural disasters c. Distribute advisory notes and implementation guides for disaster mitigation to the community d. Contact authorities responsible for planning, building, health, and welfare, issue warnings or provide fire and crowd control systems e. Ensure that citizens receive appropriate first aid training f. Work with educational institutions to implement citizen education and awareness programs e. Identify escape routes and the location of safe environments and shelters (Solway, 2004: 304):

A disaster and Risk management system is a system that requires continuity and consists of intertwined phases. According to this system, disaster and risk management consists of mitigation, preparation, rescue and first aid, recovery, and reconstruction stages (Ergünay, 1999).

1. Pre-Disaster Phase
2. Natural Disaster Sequence Phase
3. Post Natural Disaster Phase

4.2.1. Pre-disaster phase (Preparation),

The pre-disaster stage is the first stage of the risk management system consisting of mitigation, prevention, and preparation stages to save society from natural disasters with minimum material and moral damage. The main headings are as follows.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

- a. Municipalities should effectively and competently carry out all duties related to the settlement and license process and zoning within the municipal boundaries within the framework of legislation and ethics. One of the most essential conditions for overcoming natural disasters and especially earthquakes with minimum casualties is to ensure the construction of earthquake-resistant buildings produced with earthquake-resistant projects by environmental and physical plans and to prevent the construction of earthquake-resistant buildings contrary to the license and the attached project and plan. The task of ensuring the implementation and control of the existing legislation in the creation of resilient cities and structures has been assigned to municipalities within the municipal boundaries and to governorships and district governorships outside the municipal boundaries.
- b. For this purpose, it is imperative that the approval and control processes of building projects are carried out by the Department of Zoning and Urbanization by the purpose. The number of technical and auxiliary personnel, tools, and equipment capacity of the unit in terms of quantity and quality must be improved.
- c. "Natural Disaster Management and Coordination Unit" should be established in each municipality and defined in the legislation. Plans for possible disaster and risk management should be prepared and developed. "Rescue and Emergency Aid Plans, Team duties and responsibilities, training and exercise activities of personnel, regional equipment centers, stocking of critical materials, etc. should be defined and updated every 2 or 3 years.
- d. Natural disaster risk map of existing buildings should be prepared and an emergency action plan should be created. It should be integrated with the Urban Information System.
- e. Building control and inspection mechanisms should be realized continuously and effectively.
- f. Municipalities should consistently implement building heights of a maximum of 3 floors.
- g. Urban green space planning and organization should be handled holistically. Parks with sufficient area and multi-purpose functionality should be created at the city and neighborhood scale. These parks should have sufficient area size and accessibility to provide services such as gathering, accommodation, and first aid during natural disasters. Natural disaster containers should be located in each neighborhood park.
- h. Awareness and awareness-raising activities should be organized with relevant stakeholders on natural disasters. Rescue and Emergency Assistance Teams should be the first to see and take responsibility.
- i. Research and practices should be carried out for the establishment, operation, and development of natural disaster alarm and early warning systems.
- j. It is obligatory to establish a city council in each municipality. Voluntary participation should be ensured by forming a Natural Disaster Working Group and Rescue and Emergency Aid Working Group to be formed within the scope of the city council. Cooperation and coordination should be ensured with the "Natural Disaster Coordination Unit" to be established by the municipality.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

4.2.2. Natural disaster phase (Confrontation) (First 72 hours)

At this stage, the duties and responsibilities of the municipality that need to be done during a natural disaster, especially in 72 hours of vital value, can be summarized as follows;

a. The Natural Disaster Management and Coordination Unit of the relevant Municipality should convene with the relevant managers and decision makers and crisis management organization should be carried out.

Coordination and communication with other relevant units of the municipality's official AFAD and other institutions and NGOs should be ensured.

b. Municipality's "Rescue and Emergency Aid Teams" should participate in rescue and first aid operations.

c. A building damage assessment team should be formed and reports should be prepared.

d. Measures should be taken to ensure the safety of relevant public areas.

e. Necessary measures should be taken for environmental health.

f. Organization of the city's transportation and work vehicles should be made by the Municipality's Public Works Department.

g. Measures should be taken to save human lives and provide treatment as soon as possible.

h. Take measures to protect the lives and property of people affected by the earthquake from new dangers and risks that the earthquake may cause.

i. Necessary work should be done to meet the vital needs of those affected by the earthquake as soon as possible and to ensure that life in the earthquake zone, especially in settlements, returns to normal as soon as possible. For this purpose, people should be placed in city and neighborhood parks and their vital needs (such as vital water, food, clothing, security, heating, lighting, shelter, and protection) should be met.

j. Measures should be taken to prevent secondary disasters such as fire, explosion, infectious diseases, natural gas explosion, and electric shock.

4.2.3. Post natural disaster phase (Recovery):

Municipalities include the process of taking safe measures for accommodation, resettlement, and transition to normal life in the long term within the framework of cooperation and coordination with other stakeholders, especially AFAD.

a. Suitable temporary shelter locations should be identified and infrastructure and superstructure works should be carried out. Campsites such as tents, caravans, and containers should be established. Or they should be placed in intact public buildings or facilities specially prepared for this purpose.

b. Organization of processes for the identification and strengthening of low and medium-damaged structures affected by natural disasters should be carried out. Continue to provide infrastructure such as communication, transportation, water, electricity, sewerage and vital needs such as education, long-term temporary housing, and economic and social activities to return earthquake-stricken communities to normal life.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

c. Reconstruction or repair of all damaged structures and facilities according to their condition and improvement of the deteriorated economic, social, and psychological situation. The reconstruction phase may take several years depending on the magnitude and impact of the earthquake. One of the duties of the municipality defined in the legislation is to determine urban transformation and development areas (at least 5 and at most 500 hectares) and ensure that projects are designed and implemented by the legislation.

d. Identify suitable locations for the accumulation of waste and residues and take measures for their regular transportation.

5. CONCLUSION and RECOMMENDATIONS

These natural processes turn into natural disasters by causing loss of life and property due to reasons such as the fact that the multifaceted activities of people are not compatible with natural processes, people's attitudes and behaviors are not ethical, scientific and technical information is ignored and not applied, especially rent-seeking goals, political pressures and tendencies are at the forefront, damaging approaches and necessary measures are not taken. As a result, a natural disaster is a consequence and is human induced.

In our country, disaster management is managed by the central administration (AFAD). Municipalities have only assumed a support role. However, due to the centralized structure experienced in the disasters, the role or intervention effect of local administrations has been reduced especially in the first critical moments of the disaster phase and afterward, the coordination between the center and local bodies and NGOs has not been established.

For this reason, it should be ensured that technical, managerial, and legal works of local administrations should be organized within a system with the participation of the public to ensure a fast and effective rescue, first aid, temporary sheltering, and reconstruction activities to be carried out during and after the disaster with the measures to be taken before the disaster.

The following recommendations have been developed for municipalities to play a more active role before, during, and after earthquake disasters.

- To ensure governance in the field of Urban Resilience, the leadership of the mayor, institutional capacity to provide accurate and reliable data and implement the decisions taken, research institutions that can conduct the necessary research, sufficient resources to be allocated from the budget, and working groups, volunteer groups and NGOs established in the municipality working in the field of resilience are needed (Meadowcroft, 2011).
- In terms of direct participation mechanisms and "subsidiarity" of local government services within the scope of metropolitan municipalities, provincial municipalities, and district municipalities, issues such as municipal boundaries, general organization, hierarchical relations, spatial organization, definition of services and activities, etc. need to be reconsidered and revised. For example, instead of special provincial administrations serving in rural areas, the structuring of district municipalities to serve not only the center but also the entire district boundary (including villages, sub-districts, etc.) should be open to discussion.
- Municipalities should be given the necessary powers by the relevant ministry regarding earthquake disaster management.

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

- The hierarchical powers of metropolitan municipalities over district municipalities lead to the centralization of local governments (Bilgiç, 2009, p.115). This situation is incompatible with the general principles and practices of the European Charter of Local Self-Government. However, it is seen that local governments, which are not under the guidance of the central authority and which have moved away from centralization, meet local needs more quickly and economically and create a much easier and more effective communication ground with the people living locally (Parlak, 2014, p.12-13).
- Article 7 of the Metropolitan Municipality Law No. 5216 and Article 53 of the Municipality Law No. 5393 should detail the powers and responsibilities given to municipalities and, if necessary, an implementation regulation should be published.
- It should become compulsory to establish Natural Disaster Management and Coordination Units in all metropolitan, provincial, and district municipalities. An institutional natural disaster management system should be established in all municipalities. Natural disaster action plans should be prepared.
- Municipalities must create resilient cities. In this context, urban master development plans and policies should be handled and designed with holistic and ecological approaches.
- Urban green areas have a very important strategic functionality before and after natural disasters. For this reason, urban green areas should be organized at the neighborhood scale according to equality, accessibility, aesthetics, and multi-purpose functional features. Urban master and implementation plans should take into account not only social and economic parameters but also natural (landscape) parameters and should be reflected and implemented in the decision-making process.
- Municipalities have the responsibility to prepare and educate the public against natural disasters. For this purpose, disaster awareness training for vulnerable groups and all individuals, especially students, should be made widespread. It will be of great benefit for municipalities to establish disaster training centers within their means.
- To create resilient cities, it will be possible to produce ecological solutions in harmony with nature within the framework of scientific, technical, and ethical principles.

ABSTRACT

The ornamental plants sector is the newest and most advanced sector of agricultural production in our country in terms of its scope and production range. The sector includes the production, propagation, growth, and marketing of plants for aesthetic, functional, and economic purposes using different methods. Increasing environmental awareness along with the developing socio-economic structure has increased the demand for ornamental plant production in our country, especially in recent years, and ornamental plant production areas increased 2.5 times between 2002 and 2021. The production areas of the sector consist of very fragmented and small plots of land, as is the case in agriculture in general. Today, the ability of nursery enterprises that produce, grow and market ornamental plants to compete in international markets requires the sustainable production of quality goods and services by standards, and certain plans and programs, in series, with high efficiency, in a sustainable manner. Today, as a result of earthquakes, floods, and other natural disasters, the nursery sector is seriously damaged in many ways. In this context, natural disaster risk and crisis management are required for every nursery business. The study aims to reveal the precautions and actions to be taken in nursery enterprises before, during, and after natural disasters. Thus, it is aimed to create a natural disaster management guide for nursery enterprises.

Keywords: Ornamental Plants, Nursery Businesses, Natural Disaster Management, Risk and Crisis Management.

1. INTRODUCTION

Ornamental plants can be defined as plants that are produced, propagated, and grown for aesthetic, functional, and economic purposes using different methods. As can be understood from this definition, ornamental plants are a sector with a very wide scope and production range. This sector expands its foreign trade volume every year depending on agricultural and sectoral developments.

In addition, in terms of cultivation and production activities, our country has important advantages such as its ecology and natural assets, suitable climatic and geographical conditions, proximity to market countries, and cheap labor force.

As stated in official sources, although ornamental plant production areas increased 2.5 times between 2002 and 2021, the sector needs more production areas to reach its target.

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

In Türkiye, flowers are produced in an area of only 300 ha. Istanbul, Bursa, Yalova, Izmir, Muğla, Samsun, Trabzon, Ankara, Kırşehir, Antalya, İçel, Adana, İskenderun, Erzurum and Diyarbakır are among the provinces that have an important place in ornamental plant production.

As in agriculture in general, the production areas of the sector consist of very fragmented and small plots. Ornamental plants are produced in 55 provinces in Türkiye. The provinces with the highest production are İzmir, Sakarya, Yalova, Antalya, Bursa, and İstanbul.

Located in 3 different geographical regions, the production areas of private and public subsidiaries are within the scope of the 1st and 2nd disaster zones in terms of earthquakes and other natural disasters. Due to its tectonic, seismic, topographical and climatic structure, Türkiye is frequently exposed to natural disasters and ranks third in the world in terms of earthquake-related deaths and eighth in terms of those affected (AFAD) (Figure 1).

Although disasters have multidimensional and negative consequences at the global level, the proportion of scientific publications on disasters at the global level in the period 2012-2016 constituted only 0.22% of all academic publications and scientific publications on disasters and their consequences are mostly produced by developed countries (USA, UK, China, Japan) and certain countries (Kiprop, 2017). In most countries that are greatly affected by disasters, including our country, scientific studies in this field are almost non-existent.

Therefore, in these regions where such enterprises are located, it is imperative to create a guide on all measures and behaviors that should be applied and/or taken in disaster situations.

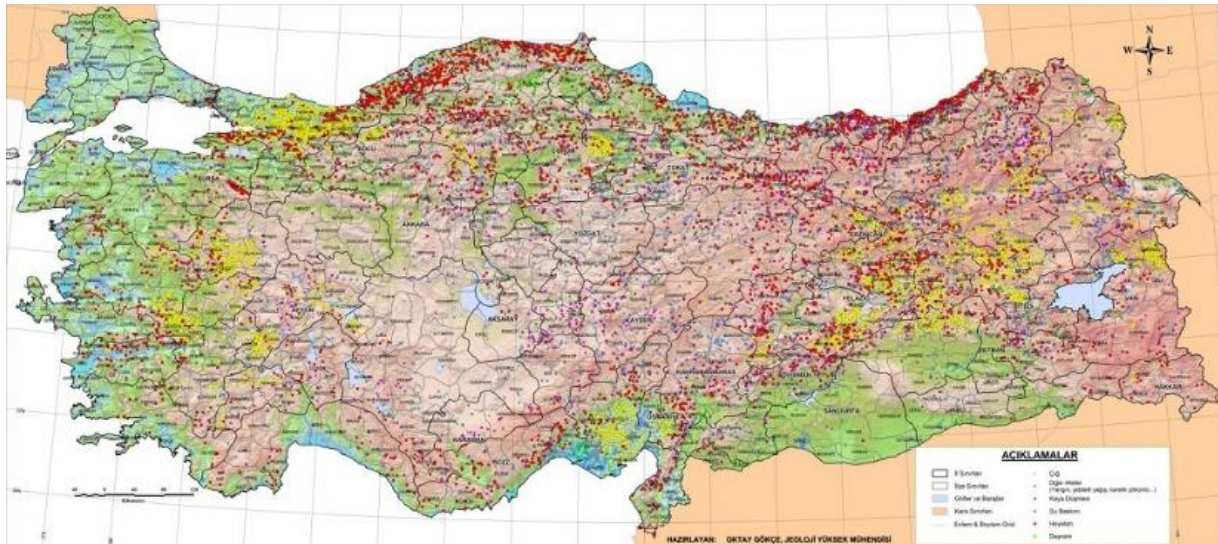

Figure 1. Map of Türkiye's disaster zones (URL.1)

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

2. METHOD and MATERIAL

The damages and losses caused by disasters are multi-dimensional. Apart from human losses, disasters pose a serious risk to global development. Disasters, which damage the physical environment and infrastructure, also destroy the environment and ecosystem, create a wide range of negative impacts on services and products, and have consequences such as economic crises, and political and social problems. In developing countries, 85% of the population is vulnerable to the effects of disasters such as earthquakes, floods, and droughts (Kuterdem & Akın, 2011).

Our country has important advantages such as its ecology and natural assets, suitable climatic and geographical conditions, proximity to market countries, and cheap labor force. It will be possible for these advantages to turn into added value and for the sector to reach the place it deserves in the world market with the solution to some existing problems. Environmental awareness in growing and developing cities has led to an increase in the production of ornamental plants in proportion to the demand in our country, especially in recent years. The main purpose of this study is to create a Natural Disaster Management Guide for Ornamental Plant Nurseries.

As a result of natural disasters, there is an urgent need to determine the damages on ornamental plant production lands and to make land plans for the new production period.

Since the existing enterprises and the lands belonging to these enterprises in the provinces where ornamental plant cultivation is widespread in our country are locations within the scope of serious natural disasters, especially earthquakes, floods, fires, and droughts, a field study was created based on the enterprise structures, land conditions, and environmental factors in these regions and options and suggestions that can be taken against natural disasters were prepared.

The land and distribution conditions of the enterprises located in Antalya, Bursa, Istanbul, Yalova, and Sakarya were examined and recorded.

It should be determined within the scope of which disaster the enterprises and land structures in the regions declared as natural disaster zones should be prioritized. Disaster zones are the regions that are seriously affected by the negative consequences of the disaster and that occur naturally without the requirement of declaring a "Disaster Zone" when urgent help is needed by the authorities (Ergünay, 2002).

- Businesses located in Istanbul-Earthquake, Flood, fire
- Businesses located in Izmir-Earthquake, Extreme precipitation (flood, erosion, landslide, drought, Fire
- Businesses located in Antalya - Strong Winds (storm, tornado, etc.) Excessive precipitation (flood, erosion, landslide), Fire, Drought,
- Bursa-based businesses - Earthquake, Fire, Flood
- Businesses residing in Sakarya - Earthquake, Fire, Flood.

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

2.1. Natural Disaster Management in Nursery Enterprises

In the "Annotated Glossary of Disaster Management Terms" prepared by AFAD, emergency planning is defined as "all activities that require timely, rapid and effective implementation of the works and procedures that need to be carried out to save human life and property and other activities from the consequences of extraordinary events with minimum loss and damage, before the events occur and during the event". According to the Regulation on Emergency Situations in Workplaces, an emergency plan is a plan that includes information and practical actions, including the work and procedures to be carried out in emergencies that may occur in workplaces. The occupational health and safety management system is a tool used to address OHS activities systematically in line with the general strategies of organizations and to solve them within the framework of a continuous improvement approach. One of the sine qua non under the occupational health and safety management systems established in workplaces is the emergency heading. Disaster Management Processes for natural disasters in nursery enterprises should consist of 3 stages.

- a. Preparation and planning phase,
- b. The stage during the disaster,
- c. Improvement and renewal phase.

a. Preparation and planning phase

The disaster management system being implemented in our country has been determined by the Law No. 7269 "Law on Measures to be Taken and Assistance to be Provided in Case of Disasters Affecting Public Life" enacted in 1959 and repealing the Law No. 4623. Under the 4th article of this Law, with the decision of the Council of Ministers dated 01.04.1988 and numbered 88/12777, how to be organized both in the centers and in the provinces and districts and the duties, authorities, and responsibilities of the institutions within the disaster response system and the principles of planning and preparation have been determined. In this context, the "Central Coordination Board for Disasters" is chaired by the Undersecretary of the Ministry of Public Works and Settlement with the participation of representatives of all existing ministries, Red Crescent, and Turkish Armed Forces (İTÜ, 2002).

*An Emergency Action Plan should be made before the disaster to prepare for disasters and to be able to respond to disasters in a timely, fast, and effective manner. It should be revised every 2-3 years.

*Risk areas and impacts in the area should be determined. Possible natural disasters should be identified.

*Early warning systems should be established.

*Emergency aid material supply and stocking should be done,

*Personnel drills for natural disasters should be conducted.

*Information and awareness raising and training activities should be carried out.

*Insurance for natural disasters should be made.

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

First of all, enterprises and land structures where existing ornamental plants are produced should be evaluated within the scope of natural disasters and survey studies should be carried out.

- *They should be redesigned to be minimally affected by natural disasters.
- *Buildings and settlement areas should be constructed according to the land structure of the enterprises located especially in earthquake zones, standardization should be made in the building materials used, and opportunities for the use of light materials should be provided.
- *Buildings and construction structures of ornamental plant production closed areas and enterprises, especially in regions and provinces with excessive rainfall, should be constructed in such a way that they are minimally affected by storm, flood, erosion, and landslide disasters caused by rainfall.
- * If possible, construction and installation should not be carried out on lands with topographical conditions (such as slope, aspect and loose slope soil parent material) in the locations where the land is deployed, and redesign and strengthening works should be carried out according to such disasters.
- *Most of the production structures and lands of the nursery enterprises in our country are located in locations where drought and consequently fire hazards can be seen intensely. The areas where production facilities are located should not be located in forest lands.
- *The usage status and location of the personnel and all kinds of necessary materials used in the facilities should not be positioned in a way to trigger fire and similar natural events, especially in summer months.
- *Personnel working in agricultural enterprises should have the knowledge and know-how to know and apply the behaviors they should do in case of natural disasters. For this purpose, regular training regarding all kinds of activities and actions should be provided.

b. Phase during a disaster

Emergency aid includes rescue of disaster victims, first aid and medical treatment to the wounded, temporary accommodation of hungry and exposed families, and provision of food, clothing, heating, lighting, and other necessities and aid to prevent epidemics (Resmi Gazete, 08.05.1988).

No matter how big the dimensions of the danger during the disaster, the higher the power of the society to resist and show resistance against the effects of the disaster, the less the effects of the disaster will be. In short, the smaller the capacity of society to cope with the consequences of the hazard, the more effective it is in the disaster (Ergünay, 2002).

- *Intervention,
- *Rescue of life and property in disasters and emergencies,
- *Health,
- *Nutrition,
- *Housing,

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

- *Security,
- *Property and environmental protection,
- *Social and psychological support
- *Evacuation,
- *Efforts should be made to provide temporary settlement services.

Since all activities to be carried out during a disaster aim to use all powers and resources of the state in the disaster area in the fastest way and with effective methods, they require very good coordination and extraordinary preparations, authorities and responsibilities needed to be applied under extraordinary conditions (Özmen et al., 2005).

2.1.2. Improvement and renovation phase

The main objective of the activities carried out in this phase is to carry out all necessary activities to meet the minimum level of vital activities such as communication, transportation, water, electricity, sewerage, education, long-term temporary settlement, economic and social activities, etc. of the disaster-stricken communities.

These are all activities that start immediately after the occurrence of a disaster and may last for several years depending on the magnitude of the damages caused by the disaster.

Providing vital needs such as communication, transportation, water, electricity and sewerage rapidly.

Determination of post-disaster losses and initiation of the necessary process for payment of damages according to the legislation.

3. CONCLUSION and RECOMMENDATIONS

Earthquake Zones Map"; Approximately 96 percent of the country's territory is at risk of earthquake zones. 98 percent of the population lives in these regions. According to TUIK 2022 data; 3.8 million hectares of the 23.8 million hectares of agricultural land in Türkiye are in the earthquake zone. In Türkiye, 16 percent of agricultural product areas and 10 percent of meadow/pasture areas are in the earthquake zone (Figure 2).

Figure 2. Türkiye earthquake zones map (URL, 2)

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

In our country, whether natural, technological, or human-induced, the practices of taking measures to reduce the damages of major disasters, whether natural, technological or human-induced, are predominantly intervention and disaster damage reduction measures to be applied after the emergencies occur rather than taking measures to reduce the damages of major disasters with planning to be done in advance (ITU, 2002). This leads to wounds that cannot be repaired both materially and spiritually after the disaster. In other words, it is necessary to give importance to risk management and adaptation studies as in developed countries in disaster management (Özden et al., 2008).

The commercial nursery sector started in the 1940s and ornamental plants are produced in a total of 20 provinces in Türkiye. Thus, it has become a sector that contributes significantly to the economy of the country. It is imperative to determine the possible risks and take precautions for all kinds of natural disasters in Nursery Establishments. For successful disaster management, it is possible to carry out "pre-disaster preparation", "response" and "recovery" processes for risk reduction and increasing resilience much more successfully. Information and awareness-raising activities against natural disasters should be carried out continuously and the issue should always be on the agenda.

ABSTRACT

In recent years, the construction sector has started to prefer more sustainable applications. As a result of these approaches, studies are carried out on more efficient use of resources, human and environmental health, energy efficiency, reduction of carbon footprint and reduction of the impact of construction and demolition wastes on the environment. As a result of these studies, biodegradable and environmentally friendly materials come to the fore. Biodegradable materials are substances that dissolve naturally without leaving pollution and toxic effects. Materials such as bamboo, cork can be given as examples. Through these sustainable materials, the carbon footprint of the building can be reduced and less waste can be generated during the construction process. By choosing these materials, the energy, resources and cost spent to produce traditional construction methods (steel, concrete) can be reduced. The benefits of using biodegradable and environmentally friendly materials in construction are that they are sustainable and renewable, as well as adding aesthetic qualities to the building. At the same time, it can be more convenient than traditional methods and cause more efficient use of materials. Architects, engineers and construction sector employees should learn the properties and usage techniques of these materials and be more conscious. The aim of this study is to review the existing literature on the use of eco-friendly and biodegradable materials in construction and to evaluate options for integrating biodegradable materials into the construction industry. Thus, by designing biodegradable building materials through eco-friendly buildings, it is aimed to reduce viable and significant waste in residential construction.

Keywords: Biodegradable Materials, Ecological Materials, Construction, Eco-Friendly Material.

1. INTRODUCTION

Eco friendly is simply defined as not harming the environment. Biodegradable is to be able to decay naturally and in a non-harmful way. There has always been a need for shelter since humanity existed. As material technologies develop, eco-friendly and biodegradable materials have become more important than traditional materials (concrete, steel, etc.).

In recent years, the construction sector has started to turn towards sustainable practices. As a result of this orientation, the use of biodegradable and environmentally friendly materials has started to increase. Research and development studies on this subject have gained momentum. In this study, some of the biodegradable and ecological materials were investigated.

2. BIODEGRADABLE and ECOLOGICAL MATERIALS

Bamboo

Bamboo, from the botanical name 'Bambusa', heavy rain suitable for growing in climates with lots of sun and high CO₂ levels (Kampinga, 2015). A bamboo grove or plantation is also a refuge for birds and many other creatures (Janssens, 2000).

This fast-growing plant was a building material used by mankind for shelter in the past (Figure 1). Today, it is still used in simple structures and different architectural structures are designed especially with the development of technology (Figure 2). As Janssens (2000), bamboo has the remarkable ability to create an "ambient", in the artistic sense of the term.

Figure 1. Traditional Bamboo House with man smoking inside, (Flores-Guevara & Lon, 1995).

Figure 2. Bamboo Sports Hall (Chiangmai Life Architects and Construction, n.d.)

III. International Architectural Sciences and Applications Symposium

September 14-15, 2023, Naples, Italy

Today, bamboo is used not only as timber but also as building material in various forms. Biocomposite materials such as bamboo medium-density fibreboard (MDF), flakeboard, plybamboo, inorganic cement board have been developed.

The advantages of bamboo are eco-friendly material, light, strong and versatile properties, fast growing and highly productive, and most importantly, self-renewing resource (Sharma, Dhanwantri & Mehta, 2014). Besides these benefits, there are also some disadvantages. Bamboo is subjected to attack by fungi and insects; for this reason, untreated bamboo structures are viewed as temporary with an expected life of not more than 5 years. Therefore, it requires preservation. In terms of joints, although many jointing techniques exist, their structural efficiency is low. And also, there is lack of design guidance and codes (Sharma et al., 2014).

The International Organization for Standardisation (ISO) has established a standard, ISO 22157, for the use of this product as a building material. This standard specifies test methods for mass per volume, moisture content, compression, shrinkage, shear, bending and tensile strength of bamboo. These methods determine the characteristic physical and strength properties. It is predicted that with the increase in research and the development of production methods, the disadvantages of bamboo can be eliminated.

Cork

The cork that we know from wine bottles is extracted from the bark of the cork oak tree (*Quercus suber* L.) (Pereira, 2007). Cork is a closed-cell foam composed by tiny hollow cells of hexagonal prismatic (Pereira, 2007) (Figure 3). It is an eco-friendly and sustainable material not only for how it is harvested, but also cause it is recyclable, or comes from renewable sources, and is biodegradable. You can use every piece of cork several times and this 100% natural element is great for insulating and last for years (Teka, 2019).

Cork is a very cheap material and can be used for without a big budget (Teka, 2019). Cork is one of the most versatile materials. It is a natural material that can be used in many areas, such as as an insulating material in construction, as a wine bottle cap, complex structures under vibration and dynamic loads are examples of their high-tech applications. As it is composed of air-filled cells, it is an excellent thermal and acoustic insulator (SPD UK, n.d.; Pereira, 2007).

Figure 3: Cork Panel (Wikipedia, n.d.)

Desert Sand

As it is known, non-renewable energy resources in our world are limited and are consumed rapidly. Global desertification is one of the most important concerns of today and future. For these reasons, desert sand, which is almost endless, can be an alternative building material and research on this subject continues.

In the study conducted by Chen et al. (2022), they produced building materials from desert sand with a solar-powered 3D printer. In this way, it can effectively alleviate the shortage of raw materials and high energy consumption during the construction material production stage, which can contribute to cleaner production. As a result of the experiment, 3D-printed samples showed compressive strengths of 62.05 ± 8.02 MPa and thermal conductivities of 1.069 ± 0.018 W/m·K, which meet the requirements of building materials (Figure 4).

Figure 4. Result of a mortise-and-tenon joint, (Chen et al., 2022)

Bioplastic

With the continuous increase in plastic consumption in the world, plastic pollution is constantly increasing. Developed environmentally friendly bioplastics dissolve in nature without causing pollution. Due to this feature, it is defined as a biodegradable and environmentally friendly material. In the coming years, it is predicted that its use in areas such as building materials, joints, etc., especially in the construction sector, will increase gradually.

Bioplastics are made wholly or in part from renewable biomass sources such as sugarcane and corn, or from microbes such as yeast. Some bioplastics are biodegradable or even compostable, under the right conditions. Bioplastics made from renewable resources can be naturally recycled by biological processes, thus limiting the use of fossil fuels and protecting the environment (Ashter, 2016). An additional problem with petroleum-based plastics is that petroleum resources are being used up; conservative sources estimate that at current rates of consumption, all known sources of petroleum on Earth will have been depleted before the end of the 21st century. Petroleum is a non-renewable resource. Today, it is used in many areas and is rapidly depleting. Considering the impact of petroleum-based plastic wastes on the environment, bioplastics are becoming important in this regard, especially since modern life is dependent on plastic (Fridovich-Keil, 2023).

3. RESULT and CONCLUSIONS

The resources in our world are limited and increasingly depleted. For this reason, it is important for resources to be more efficient, environmentally friendly and sustainable. For this reason, the use of nature-friendly and biodegradable materials will become more important in the future.

Environmentally friendly buildings can come to the fore by using bamboo. Biodegradable building materials can also be made from bamboo. Excellent heat and sound insulation, waterproof, nature-friendly and biodegradable building materials made of cork can be produced for use in our homes.

Through bioplastics, the consumption of petroleum-based plastics can be reduced, and thus, materials that pollute the environment less and dissolve in nature can be developed. And also entrepreneurs should be supported for the development of new biodegradable and nature-friendly building materials.

People should be encouraged to use ecological and nature-friendly products and their awareness should be raised.

ABSTRACT

Urban Design Quality Assessment has been developed as an important approach for the study of urban quality with several criteria and measures. This research used Imageability for the assessment of urban design quality in the streets of old Manama, the capital of the Kingdom of Bahrain. It has been going through many developments that brought many changes to the urban quality of the city. These developments have been mainly concentrated in the northern part of the city giving it a new modern character. Old Manama, on the southern side of the new city, kept its traditional urban structure. There is always a need to study the quality of urban design in such situations to understand the relationship between traditionality and modernity, and continuity and change. The assessment depended mainly on a field survey of some streets with observation and photographing. The photos then were analyzed to explore the quality Imageability through these streets. The research shows that Imageability has distinguished aspects in old Manama but still there is a need for improvement. This research also highlights the subjectivity and inaccuracy of using such criteria and measures for the study of urban character and still there is a lot to be done to improve these criteria and tools.

Keywords: Urban, Quality, Assessment, Imageability, Manama, Bahrain.

1. INTRODUCTION

What is Imageability?

Human beings are space-time sensitive. People are usually affected by the spatial and temporal settings within which they live. Events and activities through time form history and the spaces where they take place are part of it. Generally, this is the life of people inside their cities. City space is part of life perception and its image affects the way people look at the city. This perceived image is important for connecting people to their city and making them closer to it and feel belonging to it. How much this image is smart, bright, and beautiful, people will feel closer to their city and feel a stronger connection and belonging. Such a distinguished image will remain imprinted in the cognition of people and will not be forgotten. This is one side of Imageability (Cox, 2022).

Imageability is seen by Hasan et al. (2022, p. 5) as “a word that means the physical features of an urban design that define its uniqueness within its environment, a sense of place that permits its inhabitants to define it, and an aspect in determining the quality of space by eliciting powerful, lasting memories. The capacity of any physical thing to elicit a solid image for any particular observer by presenting instrumental and relevant mental pictures or patterns.”

It is the quality of the city that makes it clearly and cleanly loved, respected, and remembered by its people (Meenar et al 2019). It is the distinguishing elements of the city and their amazing characters. It is the urban design sense of these elements and their visual and aesthetical quality that give quality to the built environment (Ernawati, 2021). The image of the city is composed of the different elements of the physical urban structure of the city. Kevin Lurch definition of

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

these elements includes districts, nodes, monuments, movement spaces, and landmarks (Lynch, 1960). The level of clarity and simplicity of understanding of these elements and the images they form is the legibility quality of the urban structure of the city. It is also important here to notice that this image not only depends on the quality of the physical environment of the city but also depends on its historical, cultural, and meanings values of society (Jiang, 2012). Imageability therefore is an important quality that is needed to exist in the city to provide comfort, satisfaction, and happiness for the people. These considerations should start from the initial planning stages of the city and its development through the details of its urban design elements including street facades, street furniture, street pavements, and softscape and hardscape elements (Alamouh and Kertesz, 2022). This is in addition to the design of its urban spaces and their contents and the type of activities and functions that they have. Urban design elements and principles play a vital role in the creation of the image of the city. The design of the different elements that compose the urban structure of the city applying order, proportion, rhythm, scale, and other visual design principles is needed. Taking care of the elements of form like color, texture, material, size, and volume is also important. The functions, activities, and overall aesthetical quality of the city and its elements also play a crucial role in the creation of good urban design quality of the city. Imageability makes people feel at home in their city, it is theirs, they know it, feel it, and love it, and within it, they cooperate to take care of it and keep it alive. The image of the city with all its 3 components strengthens the sense of community involvement and belonging (Russell and Sullivan, 2020).

Urban street Imageability

Imageability should be observed in all parts of the urban structure of the city. Streets provide great opportunity for expressing and experiencing the urban qualities of the city including imageability. They are considered the most important open public space in the city. They are where a large amount of livable functions and activities exist such as shopping, entertaining, dining, walking and socializing. (Wan Ismail et al, 2018) argue that streets are important tools for recording and determining the history of the city and its inhabitants and the development of its several structures. The street is not the 2-dimensional space of the pavement where people walk. It is the 3-dimensional space enclosed by the buildings on its 2 sides in addition to the ground plan of the walking pavement. The sky view above is also part of the urban street (Abd Rahman, et al, 2019).

The street as an urban entity has 3 components. First, the tangible part of the physical environment which is composed of the buildings and urban spaces along the street with all their design elements and design principles. These are the main elements that form the visual and aesthetical qualities of the street. Second, the intangible part includes land uses, functions, and activities that exist in the street and give it its social, economic, and cultural identity. Third, there is the perceived image of the street according to the experience of its users and their assessment of its tangible and intangible components. According to this perception, the street will be considered a livable, vibrant, and attractive space that makes its users satisfied and happy. Or it will be considered as an unattractive and unsatisfactory space. As such, the street is a sensitive parameter of the quality of life in the city. It is the vein that circulates the life currents in the city and keeps it alive. Empty streets are nothing but parts of a dead city. (Alamouh and Kertesz, 2022).

Streets strongly connect to the cognitive image people hold for their city. They are the main elements that give form and character to the urban structure of the city. Not only as physical

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

spaces but also as functions and activities spaces. People usually give names to their streets according to their functions or activities or relating to cultural, economic, or historical factors, neglecting the names given by the municipality. It is the meaning of the street and the feelings that it generates that are more connected to its value and quality for its people (Cox, 2022).

2. MATERIAL and METHOD

Measuring Urban Street Imageability

Several studies provided different approaches, methodologies, indicators, and measures for the assessment of Imageability. Since 2005 Reid Ewing and several of his colleagues worked on identifying and measuring urban design qualities in urban streets (Ewing et al., 2005, 2006; Ewing and Handy, 2009; Ewing and Clemente, 2013). The result came with 8 measures for Imageability as they are illustrated in (Table 1). Ernawati (2019) listed 10 indicators that can be used to measure the Imageability of a historic street and its influence on people's preference. In their study for Imageability of the slum area of Mojo Village, Surakarta City, Indonesia Albarqi et al (2022) identified 5 variables, 17 indicators, and 25 measures. They mainly depended on the works of Ewing R. et al. Although the above review is not an extensive one, it shows that the measures of Ewing R. et al are the clearest and simplest ones. They are used in a large number of studies on the assessment of urban design qualities of urban streets. They will be used in this research for the analysis of the urban streets of old Manama.

Area of the study

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

The study area is in Manama, the capital of the Kingdom of Bahrain, opposite the eastern coast of the Saudi Arabia (Figure 1).

Figure 1. Map of the Kingdom of Bahrain. (<https://www.worldatlas.com/maps/bahrain>)

Manama is a vibrant city with a distinguished urban form and structure. This is in addition to its interesting mixture between the old development and the new development in a harmonized and integrated organic structure (Figure 2).

Figure 2. Old And New in Manama. (<https://depositphotos.com/photos/manama-bahrain-skyline.html>)

The new spread northwards over reclaimed land and followed postmodern and high-tech architectural styles. The old town remains the hub of busy economic, cultural, and economic life preserving its traditional conservationist style. The streets of the new development are modern, wide, tidy, and car-oriented, while the streets of the old town are narrow, crowded, and pedestrian oriented. Streets of the new development are giant spatial compositions with the high-rise towers enclosing their sides, but the streets of the old town are small to medium size spatial enclosures with low rise and medium rise buildings. Figure 3 shows the boundary of the study area. It is bordered from south and east by Isa Al Kabir av. and Shaikh Mohd Street. From the west there is Al Lolo Road and from the north Government av. in addition to its strategic location, the area are important monuments like Bahrain post building and Bab Al Bahrain at

Government Av. It has distinguished landmarks like Az-Zamil tower and it has important religious buildings like mosques and Matams.

Figure 3. Area of Study in Manama Old Town

(<https://www.renderhub.com/3dstudio/manama-city-bahrain-3d-model-30km>)

Methodology

This research outlines an Urban Design course exercise that was given to the the students of the Department of architecture, University of Bahrain. The aim was to train the students to link the theoretical concepts, theories, and principles of urban design to the life realities in the urban structure of the city. students were introduced to the concept of measuring urban design qualities in the built environment and the different theories and principles of the subject. For simplicity and practicality of conducting the field study, students were directed to follow the The Illustrated Field Manual for Measuring Urban Design Qualities of Ewing et al (2005). 20 Suitable streets were chosen in the area of study (Figure 4) and each street was given to a group of 4 to 7 students.

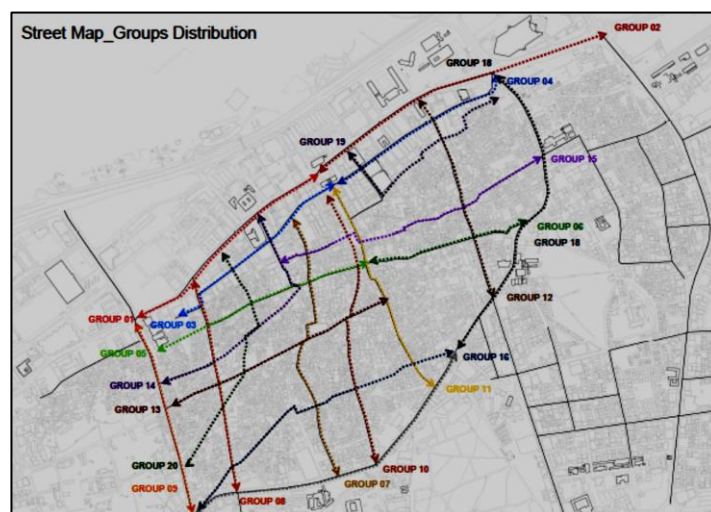

Figure 4. Area of Study in Manama Old Town Showing the Studied Streets.

Students visited the streets themselves and documented the urban design qualities of the streets with their impressions. 5 urban design qualities were studied including Imageability which is

considered in this research. Imageability of only street No. 13 is presented in this article. The segment studied starts from its crossing with Bab Al-Bahrain Avenue at east, then passing the grand mosque of Shaikh Ali Bin Khalifa and ends at its crossing with Al-Lulu street at west, (Figure 5).

Figure 5. Area of study in Manama Old Town showing the studied streets.

The street is a vibrant urban street open for private car movement. It has a variety of land uses mainly residential in addition to religious like Mosques and Matams. Ground floors are mostly for commercial use. The height of buildings ranges from 2 to 5 floors (Figure 6).

Figure 6. Map of The Street With Land Uses and Building Height.

Imageability Survey of the Street

The analysis depends on the mere assessment by the students themselves. No questionnaires were used for the general public assessment and no expert professionals were consulted as to the original manual of Ewing et al (2005) recommend.

Courtyards, Squares and Parks

Few little squares scattered along the street the largest and most significant of them are Shaikh Ali bin Khalifa Mosque square (Figure 7) and the squares of Matam Bin Saloom and Matam Bushri (Figure-1). No courtyards or parks exist in the street.

TeMALab
 Department of Civil, Building and Environmental Engineering
 University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

Figure 7. Shaikh Ali bin Khalifa Mosque square

Figure 7-1. Matam Bin Saloom and Matam BuShri (last right) squares.

Major Landscape Features

The street only has 2 palm tree and few other perennial trees (Figure 8).

Figure 8. Palm trees and other perennial trees in the street.

Proportion of Historic Buildings

It is believed that many historical buildings exist along the street. Some of them are shown in (Figure 9) depending on subjective judgement of their style and form. To determine their exact number there is a need for careful inspection and referencing.

Figure 9. Buildings Believed to Be Historical in the Street.

Buildings with Identifiers

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Generally, all buildings have clear, large and colorful signs since the street is a busy commercial street (Figure 10). Few buildings have special architectural identifiers as part of their form and structure like the minarets of mosques (Figure 10-1).

Figure 10. Buildings with to Identifiers.

Figure 10-1. Minarets of Mosques as Special Identifiers

Buildings with Non-Rectangular Shapes

Non-rectangularity is not common in such traditional quarters. Few buildings have small round corners or small round façade of a staircase. Few other buildings especially mosques and Matams have arched windows in addition to the domes on their roofs (Figure 11).

Figure 11. Buildings with round corners and staircases. Far right shows arches on the façade of Matam.

Outdoor Dining

The street has many cafeterias and small restaurants but without outdoor dining.

Pedestrian Count

The number of people in the street had 4 pedestrian counts at 4 different times Figure. The result is shown in (12 Figure).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

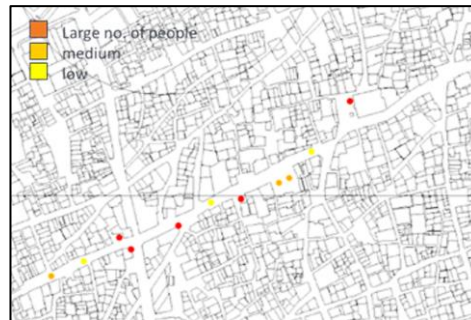

Figure 12. Pedestrian counts in the street.

Figure 12-1. Pedestrians in different parts of the street.

Noise level

Noise was observed without any technology or instruments in the street at different times and places. The results are shown in (Figure 13).

Figure 13. Observation of noise level generally in the street.

Analysis

The survey was a very interesting exercise with the participation of more than 100 students. The many discussions with the students on the routine of the survey and the results brought up these valuable thoughts. The area of study represents the heart of old Manama and the most compact area in terms of its urban structure (Figure 3). It is clear from the aerial photos that the area lacks any sense of real urban space or green structure. The street example considered is in the middle of the area and it has the same problem. The lack of green spaces, courtyards and

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

green elements was not the result of ignorance or lack of knowledge. It is the result of many important factors like environmental because of the harsh weather of Manama and the need for compact design to mitigate its effects. There is also the social factor where kinship played a major role in bringing relatives to live close to each other in the same quarter. This is in addition to the economic factor where the early days of Manama did not have much wealth. People have been living with this situation for many years feeling happy and proud of their town. The development of the town faced other problems like the expansion of northward over reclaimed land. This was because of the difficulty of redeveloping the existing areas to the south with their ownership and construction problems.

If the existence of historic buildings is a sign of good urban quality, then the area of study and the street example score very high due to the high historical value they have. Yet this cultural value collides with the need for the rehabilitation of the area. If these valuable buildings are not preserved, they will deteriorate and finally vanish. There is a need to catch up with the pace of the new development. Everybody is happy about the value of historical buildings, but only a careful rehabilitation process can develop the area and transform it into a new age.

Despite most of buildings in the street example having signage identifiers, it was not felt that this is an added urban quality or can much help in terms of Imageability of the street. On the contrary, architectural identifiers like minarets were found to be much more effective in building the special image of the street. On the other side, non-rectangularity of buildings can somehow give them some more recognizable and memorable quality but there is something very important to be noticed here. It is the overall visual design quality and aesthetics of non-regular buildings that give them significance, memorability, and Imageability. There are irregular buildings that are ugly and visually not pleasing. They will not help the image of the street or the area.

Outdoor dining spaces are crucial factors for the vitality and vibrancy of modern urban streets. This is a modern western view related to the western city and culture. Cities of different environmental, economic, and cultural settings should not necessarily be following the same model. The harsh weather conditions in Manama during many months of the year do not encourage outdoor dining. This is in addition to the social and cultural values that also do not encourage such activity. Streets narrow and the commercial functions including food and drink providers are mixed with residential uses. Privacy and social calm constrained the development of outdoor dining facilities in old Manama. The street example considered has no outdoor dining, but it has its many indoor dining spaces that greatly add to its imageability due to their cultural and social values in addition to the special traditional types of food that cannot be found outside the old town.

The pedestrian count concept of western cities cannot be applied to old Manama. Crowded streets of the western city are considered a clear sign of walkability and strong imageability. On the contrary, low pedestrian streets in Manama do not mean they have less urban quality and less attractiveness. It is all about the rhythm of life and the revolution of cultural, social, and economic wheels. At prayers time the example street will get crowded with people going to Mosques and Matams and coming out of them. The same is the case with religious events and festivals. The example street with these activities will draw an effective image more than modern streets outside old Manama. At certain times these crowds make "noise" that is considered lovely and attractive, religious and spiritual. It is not the noise of traffic or machines. Other sounds come from commercial activities are also par of the culture of the area that add to

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

its livability and vibrancy. Again, it is the subjective attitude towards urban space and its functions that can affect the formation of its urban image.

3. CONCLUSION

The model of Ewing et al (2005) is useful in giving some idea on Imageability but it is subjective, limited, and lacks accuracy in the measures. Ernawati (2019) provided subjective indicators without any idea of how to measure them except through users' questionnaires. AlBaqiri et al (2022) provided more practical details for the measuring of the same indicators of Imageability of Ewing et al (2005). They tried to take into consideration the actual real quality of the physical environment of the street. Still, it needs more development and detailing.

The complexity of the built environment needs careful consideration when it comes to the study and analysis of urban design qualities either the perceived ones like Imageability or the actual qualities of the physical environment and its functions. Therefore, urban streets need more care in considering their urban design qualities. It is crucial to consider the local cultural, social, economic, and political setting active in shaping the built environment and complementing its physical Imageability. This research also gives the opportunity to look at some aspects of the urban design qualities in Manama Old Town and it is hoped that future research will reveal more about these qualities.

Declaration of conflicting interests

The author declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Acknowledgments

A big thank you is given to the students of the Urban Design course at the Department of Architecture, University of Bahrain for their participation in the field work and the analysis of the study area. Thank you also goes to Suzana Saraiva who participated in the preparation and supervision of the exercise of Old Manama survey.

ABSTRACT

With the advent of modernization, the city's rapid development and significant changes in Jeddah's cityscape and urban fabric have occurred. In the continuation of this change, the situation of historical areas began to deteriorate. Conservation of its roots has become an important project due to change and deterioration. As it is defined as a world heritage site due to its significant heritage importance to the area. This article evaluates the ongoing conservation project in the historical Jeddah (Al Balad) region, which is on the world heritage list in the Kingdom of Saudi Arabia, in terms of the methodology adopted and the policies implemented. This article critically evaluates the architectural preservation initiatives made to preserve the buildings of this region, which are often regarded as some of the most astonishing architectural achievements in history. The study uses a qualitative research methodology that focuses on in-depth case studies from other published academic studies in Jeddah (Al Balad). At the same time, two case studies, Al Sharbatly House and Nasif House, were chosen as focused on residential buildings to analyze the criteria mentioned earlier, through the search for material restoration and analysis through qualitative research and literature reviews. As a result of this research offers a series of recommendations for improving the conservation project.

Keywords: Old Jeddah, Al Sharbatly & Nasif Houses, Heritage building, Al Balad region, Conservation.

1. INTRODUCTION

In the heart of Jeddah, a city steeped in rich history and cultural significance, lies a treasure trove of architectural heritage that embodies the essence of a bygone era. The historical district of Jeddah stands as a testament to the city's vibrant past, with its labyrinthine alleys, intricately carved facades, and timeless charm. Amidst the hustle and bustle of modern urbanization, the conservation of these residential buildings has emerged as a pivotal endeavor, intertwining the threads of cultural preservation and sustainable development. The imperative for sustainable conservation extends beyond the realm of architecture and resonates with the very essence of a city (El-belkasy, 2022). This article embarks on a journey through the complex interplay between preserving the historical essence of Jeddah's residential buildings and the imperative of sustainable practices in the face of contemporary challenges. Because due to the fast development of the city and the vast change in the cityscape and urban Fabric of Jeddah, the conservation of its roots became an essential project as the state of the historical areas start to

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

deteriorate. It is defined as a world heritage site due to its significant heritage importance to the area.

This research is to analyse and study the conservation project that is held within Jeddah historic district, strategies and methodologies that have been applied, and as the project is still ongoing also look into some of the results of the completed parts of the conservation. In addition to investigating the preservation of the heritage while maintaining the local community's socio-physical, socio-cultural, and environmental aspects.

Hence, the study uses a qualitative research methodology that focuses on in-depth case studies from other published academic studies in Jeddah (Al Balad). Case studies for developing and conserving historic urban areas were analysed and compared to the applied strategies on the two case studies area, Al Sharbatly House and Nasif House, which were chosen as the study is focusing on residential buildings as its high significance and uniqueness in terms of history and culture in the area, through the search for material restoration and analysis through qualitative research and literature reviews. As a result of this research offers a series of recommendations for improving the conservation project.

Ultimately, this article invites readers to contemplate the delicate balance between the tangible and intangible aspects of heritage, and how the lessons learned from Jeddah's conservation project can illuminate a broader path towards sustainable development that respects the past and embraces the future.

All these aims will help to answer the following questions:

- What are the conservation methods implemented by the government?
- Why is it significant to conserve heritage buildings?
- What are the complications facing the conservation of the area?

In the meantime, the only restrictions that can happen during the research can be:

- Limited resources of the conservation resolution and techniques used within the project.
- High restrictions and limitations of access to the historical buildings.

2. MATERIALS and METHODS

This research includes both qualitative methods. As a qualitative method, photographs and articles about the cultural heritage of Al Balad residences belonging to different periods are collected by examining library and archive documents.

The first case study is Al Sharbatly House, which was built about 150 years ago and was originally owned by a merchant (Sharif Abdullella Muhanna of Abdali) who regularly traded between Jeddah and the Red Sea city. (Attia, 2021) because of its unique entrance and big meeting hall, the house served as an Egyptian embassy before it becomes a permanent residence to the famous merchant Abdullah al-Sharbatly. In the past 20 years, the house was turned into a museum for a few years and now after a preservation, the function has been changed into a public tourism attraction gathering point with a roof cafe.

The second residence belonging to Bayt Nassif also known as "The House with the Tree" since it was the only house in Balad that had one. The development of Nassif House started in 1872 and it was wrapped up by 1881 for Sheik Omar Effendi Nassif, at that point representative of

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Jeddah. This house had a place for the Nassif family until 1975. One of the beneficiaries, Sheik Muhammad, turned Bayt Nassif into a private library that inevitably collected 16,000 books. (Baik, 2015).

The two selected residencies from today are known as the tourism attraction points that were renovated by the Ministry of Culture and Heritage, these two tower houses were selected for their significant history and unique architecture in addition to their social impact and image on the area.

This research aims to search and identify the quality of conservation in the historical district, a qualitative analysis will be conducted through a literature review to improve the existing conservation process and provide recommendations to enhance the process. Review two case studies to show the conservation's results and effectiveness.

3. FINDINGS and DISCUSSION

Historic Jeddah

Historic Jeddah, often referred to as "Al-Balad," is a UNESCO World Heritage Site located on the western coast of Saudi Arabia. Its historical significance lies in its role as a pivotal trading port in the Red Sea, fostering connections between the Arabian Peninsula, Africa, and the Indian subcontinent. Historic Jeddah's historical significance is deeply rooted in its maritime trade connections that facilitated the exchange of goods, ideas, and cultures between Asia, Africa, and the Arabian Peninsula. This cross-cultural interaction is reflected in the city's architecture, customs, and traditions. Studies by Al-Mulhim (2014) underscore the city's role as a testament to the interplay of cultural diversity and historical continuity. The architectural diversity of Historic Jeddah reflects its long history as a global trading hub. The city boasts an array of architectural styles, including traditional coral stone buildings, Ottoman-style houses, and grand merchant residences. These architectural elements showcase the multicultural influences that have shaped the city's built environment over time. Research by Alsharekh (2010) emphasizes the importance of understanding these architectural styles as cultural artifacts, each telling a unique story of Jeddah's past. Also, research by Al-Hathloul (2004) emphasizes the importance of these architectural elements in conveying the city's identity and heritage while highlighting the need for conservation efforts to ensure their preservation (Heba, 2022). As the city modernized, Historic Jeddah faced urban development pressures that threatened its cultural and architectural heritage. The influx of modern infrastructure and commercialization posed challenges to the preservation of traditional structures. Habib M. Alshuwaikhat a professor and former head of City and Regional Planning (2007) highlights the tension between preserving historical authenticity and accommodating contemporary urban needs. Therefore, in this point, the article focuses on the second large city in the kingdom after the capital lies one of the most distinguished architectural styles in the area, Hejazi architecture. As it resembles culture, identity, and richness in heritage, it was listed as one of the world heritage sites by UNESCO in 2014 as characterized by a distinct urban heritage that was a symbol of Hejazi architecture (Waheeb, 2022). (Figure 1).

Figure 1. Showing the historic district and urban fabric and areas with historic value Jeddah Municipality, Vol. II. p.94.

The historic district of Jeddah is located on the east coast of the Red Sea. Since the 7th century AD, the city was an important port for the Indian Ocean trade routes, through which goods were transported to Mecca. It was also the gateway for Muslim pilgrims coming to Mecca by sea. Because of these two functions, the city developed into a thriving multicultural centre

characterized by a distinctive architectural tradition, including the tower houses built in the late 19th century by the city's merchant elite, (Figure 2).

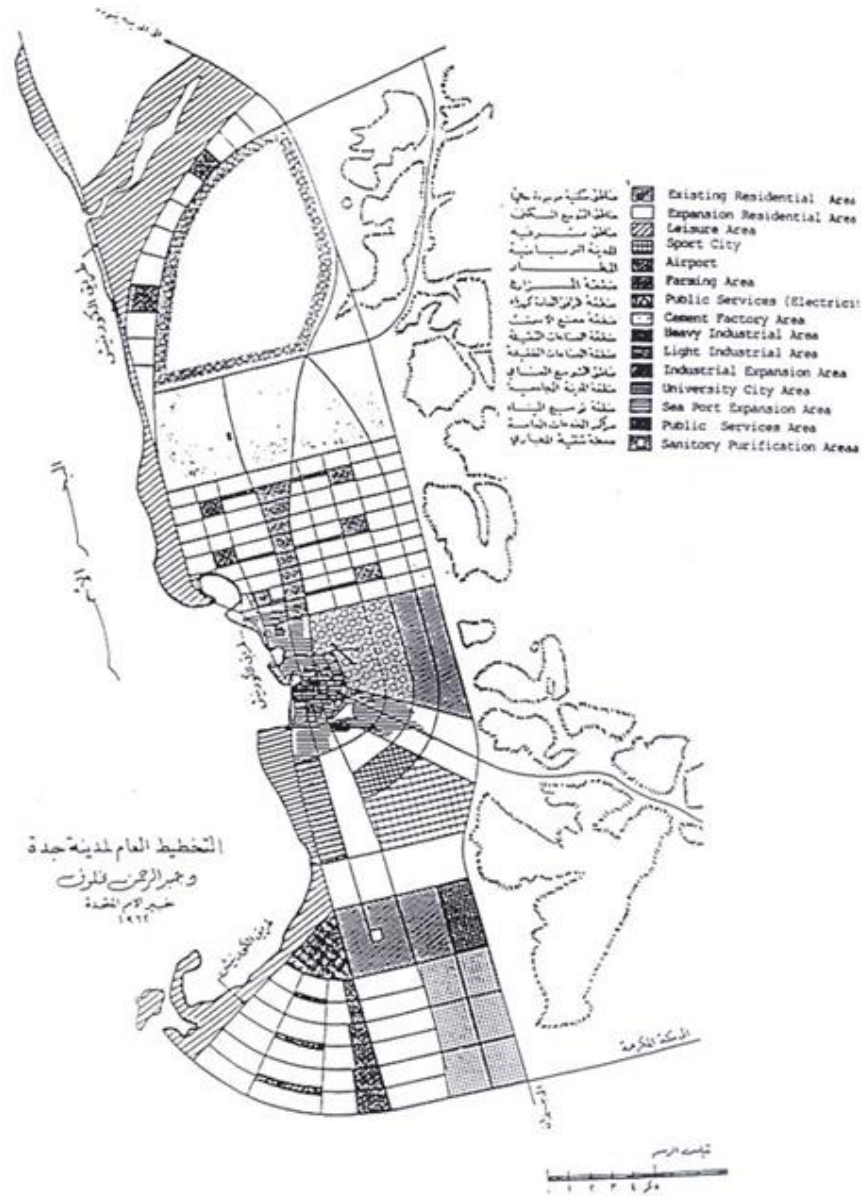

Figure 2. The First Master Plan of Jeddah 1962 by Dr. Abdul Rahman Makhlof. Source: Jeddah Municipality, Vol. II. p.94.

Jeddah City has a rich history, dating back more than 3000 years. The Old City of Jeddah features several ancient structures "around 350," which were erected more than 350 years ago with unique qualities that reflect the nation's culture. The city is located on the western edge of the Hijaz area, along the Red Sea shore. Jeddah is also the gateway to Islam's two holiest cities, Madinah and Makkah. Furthermore, this city is regarded as the Kingdom of Saudi Arabia's tourism and economic capital (Telmesani et al., 2009).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Furthermore, (Al-Fakahani, 2005) states that "Muslim and Arab scholars recognized that the name Jeddah is derived from the Arabic phrase.

Urban Fabric of Historic District (Al Balad)

The urban fabric of a historic district such as Al Balad is a testament to the rich cultural heritage and architectural significance of the area. Al Balad, meaning "The Town" in Arabic, is a vibrant and bustling neighbourhood that showcases the traditional charm and historical importance of Saudi Arabia. The term "urban fabric" refers to the physical layout, structures, and design elements that shape the character and identity of a city or district. In the case of Al Balad, its urban fabric is intricately woven with narrow winding streets, traditional courtyard houses known as "Rawasheen/ Roshan," ornate wooden balconies called "Bayt Jeddah," and grand mosques, (Calogero, 2022). This historic district holds immense value as it provides a glimpse into Jeddah's past, showcasing its cultural diversity through its unique architecture and layout. Exploring the urban fabric of Al Balad reveals a tapestry of influences from various civilizations that have shaped its development over the centuries. From Ottoman-style buildings to Persian-inspired motifs, each structure tells a story about Jeddah's history as an important trading hub along ancient trade routes. Furthermore, Al Balad serves as an important centre for commerce, with vibrant souks (markets) offering traditional goods ranging from spices and textiles to handicrafts. However, during the last few decades, the deterioration of historical regions caused by rapid socio-economic developments all over the world has also affected these historical regions. Despite its economic benefits, this rapid development has adversely affected the historical regions of the cities. It has destroyed the old urban fabric and character of the city (Chohan, 2006).

The Saudi Tourism and Antiquities Commission has prepared a document for the inclusion of the historic centre of Jeddah on the city's list of World Heritage sites protected by UNESCO (World Heritage List); This record stems from the recognition of its undeniable value as a testament to its urban-architectural testimony to the culture of the Red Sea region, as has been repeatedly emphasized: "Historical Jeddah" (Abdu, 2002), (Figure 1). From the 15th to the early 20th centuries, in the region and along the maritime trade channels, the Sacred There was a convergence of cultural contacts, technological knowledge, resources, and construction techniques in the Indian Ocean leading to the City (Badawy, 2018). AL BALAD, (figure 3), is the only urban centre on the Red Sea coastline that preserves important examples of its culture. The market (bazaar) axes are still fully preserved in this part of the historic city, as the rest of the road network is not affected by the city's transformations: the only discontinuity is evident in the gaps caused by the collapse of 'historical' structures, (Al-ban, 2016), (Figure 4).

Typology of Traditional Tower Houses in Jeddah

Traditional tower houses in Jeddah, Saudi Arabia, are known for their unique architectural features and cultural significance. These tower houses, known as "Roshan" or "Rawshan," are characteristic of the city's historic districts like Al-Balad. Here is a typology of traditional tower houses in Jeddah:

1. **Roshan Architecture:** Roshan houses are distinctive for their elaborately carved wooden screens, known as "Roshan." The Roshan screens adorn the windows and balconies, providing privacy while allowing ventilation and light to filter through. Roshans are intricately designed with geometric patterns, floral motifs, and calligraphic elements.
2. **Vertical Design:** Jeddah's tower houses are known for their verticality, with several stories that accommodate extended families and different functions. Each floor serves a specific purpose, often including living quarters, storage, and communal spaces.
3. **Courtyard and Central Atrium:** Many tower houses feature an internal courtyard or central atrium, providing an open space for family gatherings, ventilation, and natural light. The courtyard often features a small garden, fountain, or seating area.
4. **Elevated Living Quarters:** Living quarters are often located on the upper floors of the tower house to provide better ventilation and views. The upper floors are accessed via staircases, which can be narrow and winding due to space constraints.
5. **Mashrabiya and Ventilation:** Mashrabiya screens are common in Jeddah's tower houses, similar to the roshans but made of wood or latticed panels. These screens allow airflow while maintaining privacy for residents. Small windcatchers or wind towers on the roof facilitate natural ventilation.
6. **Decorative Elements:** Tower houses are adorned with intricate stucco work, geometric patterns, and calligraphy on walls and ceilings. Ornamental detailing reflects Islamic art and local design traditions.
7. **Community and Social Interaction:** Tower houses were not only individual residences but also contributed to the social fabric of the community. Neighboring tower houses formed interconnected networks that fostered social interactions.

For example, during the economic boom that followed the opening of the Suez Canal in 1869, the point connecting the East and the West of the Jeddah port became an important trade point, as a result of which the houses in Jeddah reached up to 7 floors. These houses belonged to wealthy merchants and merchants, and they became highly decorative and unique in terms of architectural aesthetics. They also recognized them as mixed-use homes as the ground floor is often used for commercial purposes such as offices or sometimes warehouses. Nassif House is one of these examples. (Figure 5).

Figure 5. An Example of the tower house, Nassif House, in Jeddah, Saudi Arabia, (New Zealand Digital Library)

The interior design of the houses is based mainly on maintaining privacy as shown in (Figure 6), especially for transporting goods implemented throughout the Arabian Peninsula the features of the house are:

- The window leveled above road level.
- Roof terraces are divided with high balustrades.
- Men/guest reception rooms are separated from women's interaction areas within the house.

Figure 6. Examples of the Hijazi architectural building in old Jeddah, (by Author)

Regulations And Policies of Conservation, Preservation, And Restoration in Traditional Tower Houses in Jeddah

The policies are applied in two main parts: Robert Matthew policies and Jeddah municipality policies. Robert Matthew's policies depend on conserving the city and buildings with distinctive urban character are preserved, linking heritage areas with new urban extensions

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

divided into two different levels: urban fabric and classification of heritage buildings Gena, 2022).

The classification was based on the historical importance and condition of the building, there were divided into 3 different groups A, B, and C.

- A- Buildings with national relevance.
- B- Buildings with regional importance.
- C- Building with local significance.

On the other hand, there are Jeddah municipality policies with the cooperation of the Saudi Commission of Tourism and national heritage developed a set of policies summarized as follows:

- Preparation of a list of iconic buildings that need preservation.
- Encourage building owners to restore their properties under the commission's supervision to ensure the best result of the restoration operation
- Preserve the original status of the area by providing suitable landscape elements to the historical and heritage site.
- Provide suitable parking areas and spread awareness among local communities through the application uses of heritage festivals and activities within the area, (Alzahrani, 2016).

1. Preservation and Restoration

The first part of historic city recovery is the execution of temporary works for the safety of severely damaged structures (demolition, shoring, installation of metal rod support, bands, hoops, etc.).

Interventions are required to:

- Prevent further damage.
- Protect bodily injury.
- Restore regular economic and social activities.

The most difficult of these tasks are those involving the selection of the best sort of intervention, good performance, and cost optimization.

The following design method needs to be followed:

- 1) Identification of the building type;
- 2) Evaluation of the damages;
- 3) Identification of the damaging mechanism
- 4) Assessment of the need for temporary operations;
- 5) Determination of the kind of intervention (structural sections or non-structural destruction, installation of temporary works to sustain vertical loads and/or retention compared to horizontal activities, and so on) and the appropriate technique for the specific condition of the building;

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

6) Provisional work in which each case is to be studied and examined separately based on the following factors:

- Building geometry and type.
- Active collapse mechanism
- Building size and damage location and the accessibility to the interior safely.
- Building materials
- The life span of the building and how fast is needed for operation.
- The surrounding area's condition and use.

2. Material Analysis

The vernacular materials used in the restoration of the building must be the same as the original material or the nearest in characteristics, the main materials that needed the most attention were the main visible which are defined as original building materials such as stone, bricks, or blocks, wood and plaster decoration in which is referred to as traditional building materials.

2.1. Stone and Mortar

Hadjar baharj is a grey hard stone block made from Madre pore stones including concretions reefs of the Red Sea and other tropical seas. These were discovered in the shallow seas of the Red Sea shore near the city of Jeddah.

Even blocks of coral (Coral blocks) were employed on occasion in construction. These have comparable characteristics as Mangabi stone (for insulation and resistance) as Shown in (figure 7), but are lighter; more expensive to remove, and were not utilized as standard material, even though coral blocks are frequently found combined with limestone.

Hadjar manqabi = Stone coral limestone formed by coral reef consolidation: this type of stone is extracted in the Manqabah lagoon northwest of Jeddah.

The stone coral was taken from the local neighborhood of the old town and was simply known as "mangabi." To the north of the old city, traces of ancient quarries may still be seen. It's a reasonably straightforward stone to cut and work with, especially if just for a brief period because it hardens when exposed to air. It is permeable, has strong insulating characteristics, and is relatively light (1.5 t / m³). To survive the corrosive effects of the saline air on the Red Sea shore, stone walls of mangabi must be plastered, as was traditional in old Jeddah.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 7. Shows several examples of Mangabi stones

Mortar restoration is a word used to designate a collection of commercially produced, proprietary materials created exclusively for the restoration of masonry units, most often natural stone and/or brick. These materials are part of the larger and less well-defined category of 'plastic' repairs (repairs using any workable substance that will stick to a substrate and solidify after application), although they should not be confused with conventionally produced tailored lime 'mortar' repairs. The term 'restoration mortar' does not denote a specific material composition. Many 'off-the-shelf' goods with drastically varying compositions are available on the market. Restoration mortars should ideally meet a variety of technical and visual compatibility requirements, such as high vapor permeance and water.

2.2. Wood

The use of wood is more interesting, especially in the implementation of bearing walls of buildings: the walls are reinforced by elements-wood (figure 8) placed chains typically every six courses of stones (each application is approximately 20 cm.) both outside and inside the wall and connected transversely to it _ not always this link appears to exist. These chains may be formed out of joists of square sections or planks, usually made of teak wood from India, and have the role of load balancing while also offering higher resistance to the buildings and stability by counteracting drooping settling. Furthermore, the building's wall construction was linked by a type of "belt-edged wooden" horizontal that was necessary to resist any shock waves that define the location.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 8: Shows wood treatment and wooden support, (by Author)

The wood was covered with mortar mixed with stone shards to provide a type of bed for later block action. An issue occurred due to termite aggression on wood, which the "masters" attempted to remedy by treating the wood with a type of adhesive / bitumen used in boat construction. However, there was still the issue of extreme humidity in Jeddah. It was attempted to solve both concerns, termites, and dampness of the wood, by employing exceptionally resistant (also in terms of the pillars and beams composing the floor slabs) materials such as palm tree trunks from a location near Mecca or certain teak obtained from overseas.

4. CONCLUSION and RECOMMENDATIONS

At first glance, the conservation project accomplishes most of its goals in terms of saving the building in the best way possible as it is under deep analysis of the heritage and culture of the area. The advantages of conservation not just saving the city's identity but also preserving this history for next generations to come, the social, economic, and environmental benefits are significant to the area, it has a great impact on people living within the area and its surrounding, it encourages investments and boosts tourism as it will change the previous image or perception of the town. The conservation and preservation of the residential buildings in the historical district of Jeddah represent a critical endeavor that transcends the realms of architecture, culture, and heritage. This project not only safeguards the physical structures but also ensures the continuity of a living historical narrative that is intricately woven into the fabric of the city. The significance of this initiative extends far beyond the preservation of mere buildings; it encapsulates the essence of Jeddah's identity and serves as a bridge connecting the past with the present and future. The undertaking of conserving and preserving these historical residential buildings is not without its challenges. Balancing the demands of modern urbanization, infrastructure development, and the imperative to retain architectural authenticity requires thoughtful planning and collaboration among various stakeholders. Community engagement plays a pivotal role, ensuring that the voices of those who reside within and around these historic structures are heard and integrated into the preservation strategies. On the other hand, there were some main issues that occurred analyzing those methods and policies, one is regarding the alternation of some materials in restoration such as the use of cement mortar which is less breathable compared to the original lime mortar which is considered more sustainable, the implementation of new materials such as reinforced concrete and steel turned out to be alien to the original materials in which integrating those modern elements are non-reversible and can not be undone. The second main issue was social, as not all building owners agreed on conservation plans, some areas were forced into it which affect them, and some others were preserving and conserving on their terms which might cause damage to the building rather than save it, so the implementation of the regulations has to go moderate in parallel with the owners where this project can benefit all parties. The reuse and changing of the function of the original structure might affect the general urban fabric of the place as most of these iconic houses were changed into hotels and general open-to-public areas also the excessive usage of the structure might affect the building durability, as controlling human activities and behavior is very difficult if it's open for public. In the end, the conservation project at the historic district is a significant right step into preserving the city and local heritage and it has almost no negative side in elevating the area into a better place. As these architectural gems are meticulously revitalized, they become more than just buildings; they become vessels that carry the stories of the people who lived, loved, and shaped the city. The project's success lies not only in the physical transformation but in the intangible heritage that is safeguarded and passed down to future generations. The conservation and preservation of the residential buildings in the historical district of Jeddah stand as a testament to the enduring power of heritage to inspire and connect across time and space.

ABSTRACT

Cities account for 60-80 percent of energy consumption and 75 percent of carbon emissions despite occupying only 3% of the Earth's territory. Cities are particularly sensitive to the effects of climate change and natural catastrophes due to the high concentration of people, infrastructure, housing, and economic activity. Building urban resilience is critical for avoiding human, social, and economic losses while enhancing the sustainability of urbanization processes is required for environmental protection, catastrophe risk reduction, and climate change mitigation. A sustainable city uses urban planning and administration to address social, environmental, and economic impacts. The quality of life in cities is strongly linked to how cities use and manage their natural resources. Cities can leave a net zero footprint for a more sustainable world by implementing planned infrastructure, public green areas, efficient garbage collection, and other initiatives. The notion of a sustainable city blends eco-friendly behaviors, green areas, and supporting technologies into the urban environment to minimize air pollution and CO2 emissions, improve air quality, and safeguard natural resources. These activities result in a healthier environment for city residents as well as a lower carbon footprint for the city as a whole. Sustainable cities are becoming increasingly important in the fight to counteract global climate change. With clean technology, parks and paths, and urban sustainability principles, smart cities are building sustainable places. The study explains the relationship, similarities, and shared goals of the categories "Smart, Green, Ecological, and Sustainable Cities" as stated. It also considers how these phrases educate societal members about the quality of life, particularly in cities, as well as how to manage the natural resources available in cities. As a result, it examines how green living habits will be promoted in households and offices. The report summarizes the findings by urging that individuals, governments, industries, and all other stakeholders be warned of the future dangers of our activities if they are not quickly checked and sensitized.

Keywords: Sustainable Cities, Smart Cities, Climate Change, Green Cities, Ecological Cities.

1. INTRODUCTION

A sustainable city is sometimes defined as one that has the least negative influence on the environment, is inhabited and governed by people who are committed to reducing the amount of energy, water, and food needed, as well as the amount of waste heat produced, and the amount of pollution produced. A sustainable city is frequently referred to as an "ecocity" or an "eco-city" in this context. A sustainable city should produce the least amount of environmental pollution, utilize the land as efficiently as possible, compost used materials, recycle garbage, or turn waste into energy. All of them ought to significantly lessen the city's overall greenhouse gas emissions that contribute to climate change. Humans only have one known home, which is Earth. It is where people find the things they need to live and survive. The biosphere or ecosphere of Earth is composed of a variety of habitats.

September 14-15, 2023, Naples, Italy

Humans obtain their requirements from the many ecosystems. In other words, ecosystems supply the natural resources needed by people and other types of life on the planet. Our ecosystems must therefore be preserved and maintained in order to benefit both the current and future generations. Ecosystems are, however, frequently harmed and destroyed as a result of the thoughtless, greedy, and uncontrolled over-exploitation brought on by fast industrialization. Ecosystem destruction affects both the environment and the animals that live there, in addition to the resources such ecosystems supply. Earth's resources are limited, but human demands are increasing right now. For instance, if a 1 km² piece of land can meet all of the demands of 1 person, then putting 2 people on the same piece of ground would result in a lack of resources. According to another viewpoint, resources would not be sufficient if a single person doubled his demands. Chan et al., (2016) Urbanization, rising environmental consciousness and concern, and technology advancement have all contributed to the urgent need and opportunity to reconsider how we design and run our cities. These related concerns have begun to converge in recent decades under the new umbrella of "smart sustainable cities" (Höjer & Wangel, 2014).

The literature on "smart cities" has developed over more than 30 years, from the earliest writings on the topic at the end of the 1980s to the current surge of publications on the topic. The word and concept's early development can be dated to the years 1985 to 1995, but after 2000, it started to be systematically utilized in urban development, planning, IT, and engineering literature (Komninos 2018). Future-focused academic-scientific research shows that the main causes of our world's shift from today will be global issues like climate change, resource consumption, natural disasters, overpopulation, and uncontrolled urbanization. It is underlined that "urbanization"—defined as the increase in carbon and other hazardous emissions—is the main cause of the temperature rise, which is classified as global warming. In this regard, it is feasible to say that the effects of the process of urbanization's growth in the number of cities and urban population can be seen in the natural environment's increased vulnerability to climate change and natural catastrophes. In light of this, it may be said that the process of economic, geographical, political, and cultural upheaval has placed the cities of the future in an ecological crisis. As a result, discussions about maintaining ecological balance are centred on sustainable urbanization and the search for sustainable cities. The impact on environmental resources is increased by urban sprawl and rapid population growth, as is the demand for physical resources in cities. Through information and communication technology, the idea of a smart sustainable city presents a framework to guarantee inhabitants a better life and safeguard the environment to maintain sustainability (Liu et al., 2022). There is a critical need to create creative energy systems in smart cities due to the world's population growth, the exponential rise in global energy demand, and the requirement for more resilient infrastructure than before (Abu-Rayash et al., 2021).

2. RELATED LITERATURE

Some of the related pieces of literature are discussed below: In his research on how sustainable urban planning offers cities a way to prevent climate change, Hameed (2020). According to him, integrated urban zones are constructed to bring together people, activities, buildings, and public amenities, with easy access to one another via foot or bicycle and a nearly perfect transportation system to the rest of the world. In other terms, sustainable development, economic growth, or an eco-city (sometimes referred to as an "ecocity") is a town designed with socioeconomic, cultural, and environmental (often referred to as triple) aspects. His study included a variety of fundamental elements of sustainable urban development and green cities

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

from many angles, allowing for extensive analysis. He continued by emphasizing how using environmentally friendly systems and materials, as well as improving indoor air quality and using high-efficiency or rational street lights, reduced the impact of a building on its surrounding environment. Additionally, those who work or live in these buildings directly benefited from these changes.

Satterthwaite (2010) noted that the borders of any urban center have an impact on its population, such as whether they are based on the built-up region or encompass peri-urban areas with little to no urban development. If peripheral inhabitants are included in official statistics, the size of a city can be greatly inflated; many cities have limits established to cover the city and wide territories around it, which may include small towns and major rural populations. The majority of large cities have many limits, such as those for the center city, the entire metropolitan area, or a larger planning zone that frequently includes numerous rural villages. Typically, residents of urban areas are those whose primary source of income is not derived from forestry or agriculture.

In (2014) Höjer & Wangel looked at the idea of smart sustainable cities. They started with five significant recent discoveries and demonstrated how they may be used as a foundation for the idea of smart sustainable cities. They contend in the same way that a stricter definition is required now for the concept to have any real meaning at all. They offered such a definition and mentioned some of the more significant difficulties with the idea.

Based on a thorough analysis of the literature in the area, Tura et al. (2022) established the connection between sustainability-oriented innovations (SOI) and the growth of smart cities. Following the evaluation process, 159 articles were carefully chosen for the in-depth investigation of the related ideas of smart cities and technologies geared toward sustainability. The findings revealed a rising tendency in this field's research articles, particularly over the previous five years. The results highlighted the value of a systemic, multi-dimensional view of innovations for the efficient, sustainable growth of cities. They determined that four key perspectives—technological, organizational, and social innovation with citizen participation, and system-level changes with innovation ecosystems—were used by scholars to discuss the SOI components in the context of smart cities. They discovered many narrowed themes beneath each primary perspective, second. Different aspects of smart cities were impacted by the numerous inventions. Recent studies focused on governance issues and the perspectives of technological innovation, but an increasing number of research outputs also reported on the advancements of other elements and perspectives, such as novel human-centric strategies like citizen engagement.

According to Anthopoulos et al. (2022), the Smart City can function as a "hub" that gathers, analyzes, and transmits data, brings people together to co-design and evolve, and manages service, material, and people flows in all city kinds. In order to standardize and regulate all city flows, the paper outlined the function, the applications, and the architecture of this "Smart City-as-a-Hub" operation called "SCHub."

Using the International Telecommunication Union (ITU) maturity model, Liu et al. (2022) built a sustainable smart city development indicator system and evaluated the maturity level of 35 Chinese towns. To identify development trends across 53 indicators and three dimensions, spectral clustering was used. Four development patterns were revealed by the results. Cities with comprehensive development brought together finishing developing aspects. By

September 14-15, 2023, Naples, Italy

government directives and with the assistance of information and communications technology, environmentally friendly cities improve the environment. Welfare cities demonstrated strong social welfare through the government's laser-like concentration, but they lacked financial assistance. Undeveloped cities were marked by innovation, trade, capital investment, mental poverty, and substandard living circumstances. According to development differences, practical recommendations are made for each kind to create a smarter, more sustainable city. Abu-Rayash et al. (2021) developed a brand-new approach to rate cities' level of smartness. An evaluation of eight key areas, including the economics, environment, society, governance, energy, infrastructure, transportation, and pandemic resiliency, was used to define a smart city. By examining several crucial factors that reflect the state of each domain in each particular city, each domain was appraised. All indications could be measured and evaluated, which increased the approach's objectivity and accuracy. The model was used in 20 places across the globe. The smart economy index for all cities doubles when the smart energy index is increased by 25%. Additionally, a moderate improvement in the smart economy index is produced by a 50% increase in GDP per capita. With a p value of 0.004, the association between smart governance and smart economy was positive and linear. The highest Smart City Index was 0.8 in Montreal, while the lowest was 0.3 in Abuja. To increase the Smart City Index score and create more resilient and smart cities, the socioeconomic and energy domains must be strengthened. In order to divide society into three strata—the micro (individual), meso (organizational), and macro (system), Costales (2022) used a systems approach. To investigate how Smart Cities were envisioned, the researcher conducted a systematic examination of the literature on smart cities. The research discovered a dualistic phenomenon—sources of innovation (SOI) and loci of change (LOC)—occurring at all places in the stratified city system through an analysis of 41 papers. In this case, LOC referred to the structures that allowed the learning curve to spread throughout the system, whereas SOI related to the perceptions of deficiencies that started the learning curve of innovation. The analysis showed a lack of focus on the human and system strata and an overemphasis on the organizational stratum.

The researcher created the Social Innovation Cycle to fill the gap. The interdependencies of SOI and LOC were incorporated into the multi-level social innovation framework to connect all strata, ameliorate power imbalances, and lessen marginalization.

By doing this, the researcher identified potential policy implementation areas for the comprehensive development of the Smart City. It was suggested that Smart City policies should concentrate on the point where SOI and LOC meet in order to promote human-centricity.

The impact of SDG institutionalization on the idea of smart, sustainable cities was evaluated by Blasi (2022). To determine the degree of congruence and prospective development areas, the researcher researched literature on smart cities and SDGs.

The findings showed that there are brokerage keywords, which are absent from the portfolio of overlapping keywords yet rank highly in both fields of literature. This was true of governance, energy, water management, and teamwork. While sharing certain similarities but being studied in distinct ways were ideas like sustainability, waste management, civic involvement, and innovation.

Based on empirical research presented in the form of case studies, Bibri (2021) created an integrated model for strategic sustainable urban development. In terms of its strategies and solutions, the model merged and integrated the three most prominent global urbanism

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

paradigms: eco-cities, data-driven smart cities, and ecologically data-driven smart sustainable cities.

The study's primary contribution was to offer a novel strategy for creating future models for sustainable urban development as well as practical knowledge about how to create transformative strategic planning processes for sustainability based on integrated methods.

The suggested methodology helped cities that were regenerating as eco-cities, earning the title of eco-cities, or ostensibly planned to be or become smart eco-cities in the big data era go closer to fulfilling the long-term sustainability goals.

Relationship Between the Cities

There are so many words that could imply something or mean something related to something else. Smart city, green city, ecological city, and sustainable city are a few of these terms. In the long run, all of these cities strive to accomplish comparable goals.

Therefore, smart cities are green cities, ecological cities, and sustainable cities since they strive to improve human well-being.

Smart cities utilize electronic techniques and sensors to gather data and enhance the effectiveness and sustainability of their services and operations.

Fig.1: Smart city example

Green cities are those that have been planned with the influence on the social, economic, and environmental landscape as well as providing a stable environment for present and future people in mind.

Education, health, food and nutrition, green homes and buildings, water and sanitation, green public transit, accessibility to green energy, recreation places, and community support are all aspects of social development.

Included in economic development are: green economic growth, the creation of good jobs, the generation and distribution of renewable energy, and technological and innovative advancements

Forest and soil management, waste and recycling management, energy efficiency, water management, air quality preservation, and adaptation to and mitigation of climate change are all part of environmental development.

Planning, decentralization, reducing inequities, bolstering civic and political rights, and supporting connections across local, national, regional, and global levels are all aspects of urban governance.

Table 1: Cities with indicators and their objectives

Cities	Indicators	Objectives
<p>1. Smart Cities, 2. Green Cities, 3. Ecological Cities, and 4. Sustainable Cities.</p>	<p>Jobs, Income, Housing, Access to services, Education, Political Participation, Health, Environmental Quality, Personal Safety, Community, and Life Satisfaction</p> <p>Economic, Gender Issues, Migrant and ethnic, and Inter-generational Issues</p> <p>Energy, Climate, Biodiversity, and Material footprint</p> <p>Health and social, and Institutions</p>	<p>1. Well-being - the state of being comfortable, healthy, or happy</p> <p>2. Inclusion - the practice or policy of providing equal access to opportunities and resources for people who might otherwise be excluded or marginalized, such as those who have physical or intellectual disabilities and members of other minority groups</p> <p>3. Sustainability - meeting the needs of the present without compromising the ability of future generations to meet their needs</p> <p>4. Resilience - the ability to withstand adversity and bounce back from difficult life events</p>

Table 1 shows the main goals of all the cities (smart, green, ecological, and sustainable). With the indicators of Jobs, Income, Housing, Access to Services, Education, Political Participation, Health, Environmental Quality, Personal Safety, Community, and Life Satisfaction, it was demonstrated that all cities are essential for human well-being, inclusion, sustainability, and resilience. Economic, gender-related, migrant and ethnic, intergenerational, and environmental issues. Other issues include energy, climate change, biodiversity, and the material imprint.

3. THE MEETING POINT FOR SCIENTISTS

Smart, Green, Ecological/Eco, and Sustainable cities all strive to offer a stable home for current and future generations without damaging the environment's ecosystems and natural resources. They might also include environmentally friendly options in the design of city streets, such as bike and walk lanes. They also aim to preserve the natural world and promote the health and wellness of the city's inhabitants. This is the meeting point of scientists all over the world.

4. CONCLUSION

Being a sustainable city is not an easy task. It takes a lot of political will, money, dedication, and perseverance over an extended period of time. In order to provide its residents with a good quality of life, a sustainable city undoubtedly blends sustainable growth with sustainable solutions. All of the city's stakeholders must be able to understand, believe in, and commit to the city's ambitious green strategy or goal. A sustainable city should set a high goal to achieve CO₂ neutrality by 2025, or at the absolute least, drastically reduce its CO₂ and other greenhouse gas emissions. If a city ignores climate change and adaptation, it cannot make the claim to be sustainable.

As a result, the city needs a climate adaptation plan and a program to be climate resilient. The city's transportation system can be made more environmentally friendly by using public transportation, bicycle and pedestrian strategies, clean energy cars, green structures, and the banning of toxic and damaging materials. Additionally, residents' consumerist lifestyles can be replaced with more simple ones.

The city must have implemented plans and initiatives to address each of the 17 UN SDGs. In the same vein, the city should prioritize developing a green and sustainable society. Although most towns currently only use a small portion of renewable energy, the ultimate objective of a sustainable city should be to have 100% renewable energy by 2050. The principles of participation, debate, collaboration, societal responsibility, and income distribution—all the pillars on which the contemporary sustainability movement is based—should be embraced by sustainable cities as a matter of policy.

It is necessary to implement laws on sustainable development in cities that are effectively enforced. While harshly punishing individuals who continue to use non-renewable energy sources, cities should offer sufficient incentives for low-carbon technologies and renewable energy production.

Finally, a sustainable city should include opportunities for social engagement, business transactions, trade, and leisure. For civil society to function effectively, there must be sufficient and appropriate public areas. For the sustainable city to encourage participation, recreation, pleasure, accessibility, and convenience for individuals who live, work, and relax, designated roadways, parks, green spaces, water spots, public squares, and cultural locations must be planned. Interactions between cities and their inhabitants are essential for a sustainable city.

September 14-15, 2023, Naples, Italy

The city should no longer be entirely managed and ruled by elected officials, but rather take on a shared responsibility with all stakeholders working toward a people-oriented city in their individual capacities. Ownership is the only way for city dwellers to truly commit to making their city a better place to work, live, and play.

SMART CITIES OF THE FUTURE

Associate Prof. Dr. Teodora Rizova (ORCID: 0000-0002-1602-1258)

New Bulgarian University, Master's Faculty, Department of Administration and Management,
Sofia, Bulgaria
Email: trizova@nbu.bg

ABSTRACT

The article discusses the concept of a smart or intelligent city and whether there are similar cities and technologies in Bulgaria. It also presents how smart cities respond to climate change and changes in the environment we live in, what challenges face smart cities, what their main purpose is and what are the effects of smart cities, what and how they will manage to improve. Sofia is ranked 107th out of a total of 118 ranked smart cities according to the "Smart City Index 2022"¹ of the Management Development Institute at the Singapore University of Technology and Design. In order to turn Sofia into a smart, sustainable and easily adaptable to climate change city, it is necessary to work both structurally and technologically in the areas of health care and security, recycling, mobility, utilization of green areas, as well as in the management sector. It is necessary to build and strengthen innovative ecosystems and new technologies, and promote interaction between education, science and innovation.

Keywords: Smart City, Climate Change, Innovative Technologies.

1. INTRODUCTON

In recent years, the concept of a smart or intelligent city has entered more and more into our daily life and work, in the media and scientific circles. Smart technologies that have a positive impact on lifestyle are increasingly being adopted in major cities around the world. Numerous studies on smart cities and technology have also appeared.

A smart city can be both the whole city and a certain territory of it, where electronic and technological infrastructure, such as information and communication technologies, are used to collect data and make real-time analysis, providing certain important services to solve urban problems. With the growing need for sustainable cities in the global context of climate change, the concept of a smart city places the environment and surrounding climate, including the interaction between technology and nature, promoting the integration of climate strategies and citizen participation in order to adapt from climate impacts.

The main goal of a smart city is to improve well-being and adapt to climate change by providing services that support each and every resident. Smart cities improve the daily activities of the city, such as public transport and mobility, electricity and water supply, sewage systems, etc. Using this data, local governments can extract useful information and provide effective solutions to correct prevailing urban problems.

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

According to the Smart City Guidebook² of the Ministry of Economy, Trade and Industry of Japan, its effects vary widely, and examples of expected results are described below:

- **Society:** realization of a safe, high-quality life for the residents

Effect of realizing social inclusion that allows all residents to live equally, by providing more efficient city services in all areas, including administrative procedures, purchases, transport, medical care, health and tourism, as well as providing services that meet individual characteristics and preferences.

- **Economy:** implementation of sustainable and creative urban management and economy

This direction would have a positive effect in several directions:

Creating an environment in which different services for residents and companies are implemented one after the other, using different data and new technologies that revitalize the regional economy,

Driving the regional economy through the consumption and purchase of services by residents and visitors who come and go in a safe, convenient and comfortable city, as well as creating diverse innovations through interactions, increasing the efficiency of systems in companies and governments and improving productivity.

- **Environment:** implementation of ecologically clean cities and regions

Effect of optimizing the use of energy/resources in accordance with the actual travel of people and goods in all situations, such as business operations, daily life and travel behavior, realizing a decarbonized society.

One of the main expectations is to improve overall services by collecting and using different data from a diverse range of sectors. Another expectation is to solve the challenges with new frameworks through the participation of scientific institutions, industry and government, as well as involving residents from many cities.

A smart city can change our way of life by ensuring fairness and inclusion of residents to enjoy smart services equally, protecting privacy in the use of personal data, including personal information, from the perspective of providing high-quality services that comply with the needs of individual citizens and consumers. Ensuring interoperability, openness and transparency by implementing the data platform interoperable with other regions and systems for nationally effective smart city promotion. Ensuring the safety of the services provided, continuity of the system in emergencies, including during disasters, etc. Ensuring operational and financial sustainability that is carried out by a core organization. An example would be a local government on the one hand. On the other, it is public, private and academic entities that cooperate appropriately, play their roles to be functional and flexible and bear the costs of maintaining the system and providing services.

There are numerous examples and applications of smart technologies. These can be in the form of software decision-making, smart technologies connected to other devices via the Internet or

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

applications that allow the user to control their devices easily and conveniently and can be connected to an external service provider. It is important to mention here that smart technologies help to reduce energy and thus have a beneficial and long-term impact on climate change adaptation.

Smart home technology has become very common in recent years. They cover a wide range of applications such as security systems, lighting systems, smart cameras, remote controllers, sockets and plugs. These technologies can provide remote access to the homeowner as well as allow the user to perform various home automation tasks such as turning off lights, applying door locks, monitoring around the home, and more.

Devices such as smart thermostats, for example, can show how much energy is being used when changing the temperature in our homes, resulting in much less energy being wasted.

On the other hand, smart lighting can reduce electricity consumption by using dimming lights on streets without pedestrians or traffic. Such lighting systems are often also equipped with central management software that monitors usage and drives maintenance efficiency.

An example of smart management could be a waste initiative. A city that implements innovative waste management solutions can reduce costs by emptying waste containers by using sensors installed in the containers. Sensors can monitor the individual waste level and thus the containers are only emptied when they are full, rather than on a standardized schedule. Thus, the traffic is also reduced, since there are fewer specialized vehicles for waste on the streets, which in turn contributes to the reduction of greenhouse gas emissions, improving the air and climatic conditions in the cities.

In Bulgaria, in recent decades, we have witnessed an increase in the use of electricity, the transport network is becoming increasingly congested due to the excessive use of private cars, and we are observing inefficient use of public transport. The temperature in the city increases and air quality deteriorates, as a result of global and local climate changes and human activity, the carbon footprint on the environment increases and many other urban problems that lead to the search for solutions for the development and implementation of innovative, energy-saving and low-carbon technologies.

An example is the WiFi4EU³ initiative through which the European Commission promotes free Wi-Fi for citizens and visitors in public spaces such as parks, squares, public buildings, libraries, health centers and museums throughout Europe. In this way, everyone can be connected regardless of where they live. According to the European Commission, 232 out of a total of 265 municipalities in Bulgaria have received a voucher for WiFi4EU.

Another example is the entry of radio networks on the Bulgarian market, which are intended for the implementation of the Internet of Things (IoT) - solutions related to air monitoring, garbage disposal, agriculture, management of the support networks for water supply and the energy sector.

In Sofia, the service for shared trips with electric scooters is now available with the idea of freeing up and reducing traffic in the central parts of the capital, which allows the use of fewer private cars, which in turn would improve the environment and the urban way in the long term

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

of life. In less populated areas, the process of implementing smart and innovative technologies is at an early stage.

It is necessary to work in the direction of improving the infrastructure, the use of innovative and low-carbon technologies and improving the knowledge and awareness of citizens about smart decisions and how to be sympathetic to the improvement of the areas and neighborhoods where they live.

Out of a total of 118 ranked cities, Sofia is only in 107th place, according to the annual report prepared by the Institute for Management Development at the Singapore University of Technology and Design (SUTD). Smart cities are ranked based on economic and technological data, along with their citizens' perceptions of how "smart" their cities are. Every year more and more cities are added to the survey. In 2022, the first places are headed by Singapore, Zurich and Oslo. The list also included cities such as Leeds and Glasgow in the UK, Bordeaux and Lille in France, Kiel in Germany, Medina in Saudi Arabia, Istanbul in Türkiye and San Jose in Costa Rica.

According to the results of the Smart City Index 2022⁴ ranking, there is much to work on in Sofia, both structurally and technologically, in the areas described below:

Health and safety: The sanitary conditions in the poorest areas, the provision of medical services, the cleanliness of the air, etc. are rated low by the local population. A major problem here is the lack of online reporting of problems in the city to ensure quick solutions. There is a lack of platforms and website to allow residents to easily get rid of used and unwanted items. Public safety is also rated low.

Recycling: Services related to recycling are also rated low.

Mobility: The main problems are traffic jams, unsatisfactory public transport, lack of applications for traffic flow awareness to reduce congestion, as well as pointing to free parking spaces to save time. Activities related to the utilization of green areas are still in their initial stages.

Government sector: the city receives a very low score for the criterion "easily accessible information about local government decisions ". Residents contributing to local government decision-making and providing feedback on local government projects are also rated low. Online public access to city finances and platforms where residents can offer ideas to improve city life are also rated low.

It is also important to note that national and local governments have a crucial role in the development of smart cities, and the role of each resident is paramount in solving urban problems and adapting to climate change. An example of this could be the voluntary participation of residents in smart city and technology initiatives, encouraging friends, family and colleagues to use bicycles, play sports, participate in landscaping and tree planting initiatives, promote urban vegetable gardens, clean and maintaining inter-block spaces, supporting and creating local art, production or business related to bio- and natural products, etc.

INSIGHTS FOR AN URBAN INFILL ARCHITECTURAL CONCEPT: THE CASE OF CHUECA/ MADRID

Mira Naif Haddad

School of Architecture and Design, IE University, Spain.

Email: mnaifadelhad.ieu2021@student.ie.edu, mirahaddad232623@gmail.com

ABSTRACT

Chueca is a vibrant neighbourhood located in the heart of Madrid, Spain. It has become one of the most favored areas in Madrid for both the local community and visitors because of its lively atmosphere and cosmopolitan character. Chueca's urban landscape is characterised by significant architecture, integrating historical buildings and modern design structures. Chueca's narrow streets are lined with picturesque balconies, colorful facades, and hidden courtyards, creating an enchanting ambience. The neighbourhood's urban planning and design encourage pedestrian-friendly streets, allowing the local community and visitors to explore its charm on foot and truly immerse themselves in the captivating atmosphere. This project paper attempts to present an urban infill case study in a characteristic area of Chueca. The accessibility and circulation central concept of the project allows for interactions between these different user groups. The paper illustrates how the applied design concept of the project can hold temporary and permanent events through its functional programs according to the needs of the site, the local community, and the visitors. Thus, this can assist in achieving a socially sustainable interaction within the local community while maintaining the particularity and the needs of specific project users.

Keywords: Social Sustainability, Local Community, Circulation Concept, Temporary and Permanent Programs, Pedestrian-Friendly Path.

1. INTRODUCTION

In many world cities, approximately everywhere, an older city core represents a unique historical link with the past. These historic cores are surrounded by modern urban structures (Haddad and Fakhoury, 2016). However, due to their fast growth and transformation, their social structure and economics present a genuine challenge to their natural and cultural resources. Urban settings and features, such as buildings, paths, streets, neighborhoods, and green open spaces, exert continuous influence on the quality of urban areas, thereby shaping cities as more or less livable, where residents can access the quality of life in their neighborhood, offered by the private and public service provision.

In the case of the urban historic cores, the historic houses are the most critical evidence of the past lifestyle (Fakhoury and Haddad, 2016). They are "the physical manifestation of the social and cultural traditions which have developed to give the modern city and society its meaning and character" (Steinberg, 1996, p. 465). Understanding, thus, the change in urban development is critical in studying urban dynamics, managing resources, and providing services in these rapidly changing built environments (Al-Khader et al., 2009; Haddad and Fakhoury, 2016).

Considering such aspects leads to a better understanding of the dynamics of urban heritage change and its role in altering the cultural landscape. According to the Burra Charter (ICOMOS, The Burra Charter, 1999), one negative impact is represented in the destruction and removal of

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

the urban heritage with cultural significance⁵ for new construction. This situation is more evident in the capitals, where the fast pace of urbanisation mainly threatens different archaeological and cultural heritage (CH) resources, where the nature and direction of urban change today are more dependent on the globalisation effects and economy than ever before.

Many major historical areas and heritage sites distinguish many capitals in the world, some thousands of years old; these are often located mainly adjacent to the old city centre and are now surrounded by contemporary urban structures, as in our case, in Madrid (Figure 1). Madrid City represents a real example of the interaction between modern and urban heritage sites and urban landscapes.

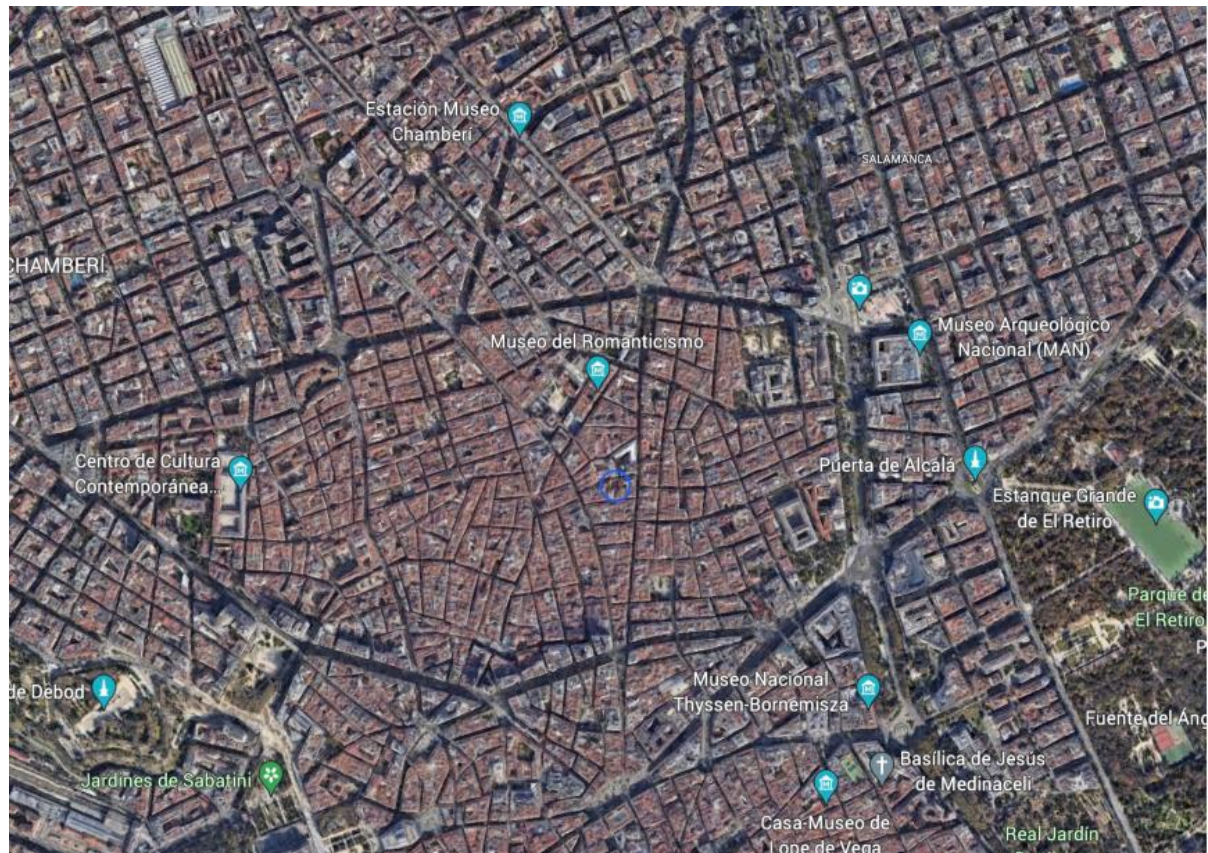

Figure 1. Aerial photo of Madrid City. The blue circle in the centre of the photo shows Chueca.

Chueca is a vibrant neighbourhood located in the centre of Madrid (See Figure 2). It has become one of the most favoured areas in Madrid for both the local community and visitors because of its lively atmosphere and cosmopolitan character. Chueca's urban landscape is characterised by significant architecture, integrating historical buildings and modern design structures (See Figure 3). Chueca's narrow streets are lined with picturesque balconies, colourful facades, and hidden courtyards, creating an enchanting ambience. We can see a connection and integration between historical and modern buildings simultaneously. They can be in the same building with different uses (See Figure 3) or in the same street. The neighbourhood's urban planning and

⁵ Cultural significance means aesthetic, historical, scientific, social, or spiritual value for past, present or future generations (article 1.2).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

design encourage pedestrian-friendly streets, allowing the local community and visitors to explore its charm on foot and truly immerse themselves in the captivating atmosphere. An interesting landmark of the area is the Architects Association (COAM) modern building, one of the first projects on the site, connecting the site that links two parallel streets together. However, the community can also use it because it is characterised by a significant landscape and intelligently integrating historical and modern buildings (Figures 2 and 3).

Figure 2. Part of the Chueca neighbourhood located in the centre of Madrid, the Architects ' Association building, with the white V shape colour and the project site

Figure 3. Images of Cheuca's narrow streets that integrate historical buildings and modern design structures in the study area on the left and images of the Architects ' Association building on the right.

This project paper discusses the case study mainly conducted as part of the design project at IE University in Spain to propose a regenerating infill project at the Chueca historic district within the Historic urban core of Madrid (Figure 4). The proposed design aims to provide special consideration and functional programmes for significant locations within the study area. In brief, the study aimed at developing the critical infill building project, within a culturally significant area and its main related open space, to serve as a centre for IE youth, diverse local users and visitors. It attempts to organise an urban infill project as a case study in this characteristic area of Chueca, based on increasing the accessibility and pattern of circulation as integral approaches for the concept, to allow for the interaction of the different user groups. As in the case of the Architects ' Association building project, which allows for two parallel streets to interact with each other, this proposed design project adopts further this idea, emphasizes it

and allows for a connection between two other parallel streets, thus integrating the accessibility for four streets to host different user groups. The only object blocking this was an empty small house without cultural significance. For this project to happen, this building had to be demolished (Figure 4). The adopted accessibility and circulation concept in this project allows for interactions between these different user groups. The paper also illustrates how the applied design concept of the project can hold temporary and permanent events through its various programmes according to the needs of the site, the local community, and the visitors. Thus, this can assist in achieving a socially sustainable interaction within the local community, while maintaining the particularity and the needs of specific project different users.

Figure 4. A detailed photo showing Cheuca's Architects Association building on the left and the project study area on the right

2. MATERIALS and METHODS

The paper shows the increasing need for studying how to deal with the interaction between infill modern projects, heritage setting and urbanscapes, while maintaining a socially sustainable urban heritage fabric since the project has a critical location in the historical neighbourhood of Chueca in the centre of Madrid. Of importance is to consider that the image of the cities that have "grown historically over the centuries cannot be put on ice during conservation" (Deslagen, 2009). Meanwhile, Cherchi (2015, p. 269) shows how reusing abandoned edifices and outdoor open spaces "constitutes a significant opportunity for achieving more liveable and healthier cities through the regeneration of inner-city areas". A place is considered livable when designed to ensure safety, promote health, attract a diverse range of users, and fulfil their diverse needs (Southworth, 2005). The livability and quality of a place concept is related to development centred on the predominance of a street life, a sense of urbanity, walkable neighbourhoods, and linked communities which enhances urban 'livability' and is strongly supported in current practices (Beattie and Haarhoff, 2018). The practice of Infill urban heritage projects and management, however, is an essential tool to create a balance between the preservation of the character of existing heritage and the changes brought by the urbanisation process in the context of the overall capital local community and visitors' needs and the needs of the site to achieve social sustainability. Socio-cultural sustainable redevelopment of historic urban environments should make spaces for local people rather than preserve certain traditional forms as cultural symbols. Still, some traditional forms that evolved from collective memory and traditions can be widely reused with community involvement in

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

architectural and urban regeneration (Fakhoury and Haddad, 2016). A careful decision-making process in these infill projects is required to reach a satisfactory policy in a complex urban heritage environment. The methodological approach of this research in this infill project is infusing this historic area with its full role as a place of living, socio-economic and cultural creation, and shared enjoyment and memory. Thus by utilising compatible activities, we can enhance it. Attracting the youth and university students to visit and arouse their interest to provide further to the local cultural identity could thus restore and add to the site's collective memory. A complete site survey was conducted for the area under study, forming the Chueca historic neighbourhood and the adjacent area, combined with a detailed photo survey and Model of the relevant components in the urban environment (See Figures 3 and 5). The well-documented photo survey of the significant street elevations and sites of interest facilitated a better interpretation of the identified physical and non-physical patterns and their locations. The visual image of Chueca's historic neighbourhood offers a variety of values and sense to the understanding of the physical space by the imagery it attributes to it, thus one recognises the key culturally significant elements of the urban fabric and formation of Chueca. The effort presented in this paper falls mainly in two directions: first, identifying the different aspects of the currently existing situation of the selected site and adapting to new urban practices within the surrounding area while considering its impact on the existing urban heritage of the area; and second, proposing several functional suggestions and solutions to enrich and empower the current situation. Hence, enhancing the pedestrian network at the project site can benefit the local community's quality of everyday life and its visitors (Figure 5). Specific trails and intersections at the site could also elevate the locals' and visitors' visual and aesthetic experience. This can greatly support the potential visitors' attraction. The project also illustrates how the poposed programmes of a circus, rythmic gymnastic, workshop and exhibitions, spa and research spaces in addition to the network of open spaces, climbing and green surfaces can hold both temporary and permanent events throughout, even addresses day and night, reflecting the needs of the site, the local community, and the visitors. Thus turning it into a connecting vibrant attraction, achieving further social interactions for the local community, while maintaining the particularity and the needs of diverse project users (Figure 5).

Figure 5. Photo and illustrations showing the process models of the project idea with the hidden court's main characteristic of the Chueca area and the concept of spiral circulation flowing vertically to accommodate different suggested activities.

3. FINDINGS and DISCUSSION

The project presents a brief discussion and evaluation of the existing conditions of the current urban context and urban formations, based on a rapid assessment and observations by the author of this paper, who was involved in different activities and analytic studies concerning Chueca during 2022-2023. The built-up area and urban fabric of the site surroundings are dense, with hidden small open courts. Historic buildings of different eras form the continuous main facades of the vibrant streets, in addition to modern buildings such as the Architect's Association building. Additionally, the area hosts diverse communities and is vibrant.

This part lists the proposed urbanisation infill design aspects associated with the urban development process in Chueca, while considering its impact on the historical asset. It focuses on analysing, evaluating, and proposing a socio-cultural node related to enriching urban accessibility; it also presents the concept of developing this site by the conception of linking two adjoining parallel paths or streets to enhance and empower the cultural significance of the urban tissue, while not allowing any activity that may cause deterioration to its value within the context of heritage buildings. This paper supports rethinking the role and intentions of infill projects in heritage neighbourhoods, so as not to only protect the initial zoning/boundary of any heritage block, but create a connection between streets and adjacent spaces which can enhance and infuse the cultural significance of this urban tissue. This proposed infill suggests a sustainable project approach in this historic neighbourhood by presenting itself as a civic landmark and a cultural and a social meeting place, capable of strengthening the civic characteristics and, at the same time, allowing dynamic relationships in the lives of its citizens and visitors. Living in this area can be sometimes stressed, and what is needed is a direct intervention in the physical structure of the selected site to convince people- and especially decision-makers - that it is a thoughtful attempt to stem the decline of some urban empty spaces and reinstate it as a core site in Chueca for 'people'. In addition, traditional and historic architecture can still be transformed according to the socio-economic conditions of each specific era requirements because it is "a living organism that grows over time, and it cannot be put on ice during conservation" (Philokyrou, 2015, p. 120; Haddad and Fakhoury, 2016).

Figure 5 shows the process models for the project idea. The concept of the suggested building matches the surroundings with the hidden court's main characteristic of the Chueca area. According to Fakhoury and Haddad (2016, p.2), traditions that have progressed into traditional forms can be widely used and reused "in contemporary architectural and urban design projects,

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

with proper community involvement". This can be understood if we accept that re-functioning historical and traditional structures to modern practices is only "a tool for carrying the traditional environments into the future, both physically and socially". However, the actual task is to be ingenious "to imagine uses which offer intellectually stimulating options, in the belief that the production and consumption of cultural goods, of art, could constitute business, could ensure adequate economic returns, changing and evolving the common commercial standards" (Giani et al., 2015, p.45).

Figure 6. Collage poster of the concept reflecting the repair program based on a spiral circulation towards the roof top, and sketches of the diverse circulation and stairs 'use patterns and their various programmes/functions'.

Of importance is to emphasise that the project programmes were designed for uses which offer intellectually and physically stimulating options and deal with different users' by providing temporary and permanent events; meanwhile, the central concept is allowing for interaction from both parallel streets and, therefore, creating connections to four parallel streets altogether, thus allowing for the diverse users to interact including the local community. Figure 6 shows a collage poster of the concept reflecting the repair program based on the circulation concept and urban accessibility approach and intelligent functions. As in our case, the continuity of the pedestrian movement between two parallel streets flowing onto the roofs and spaces would

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

enhance the user experience. Thus, a network of pedestrian routes flow into the site linking the different neighbourhood streets and district. One of the main outdoor functions is a circus and outdoor Exhibition. Meanwhile, on top of the building is a designed platform area to view Madrid from the top, thus liberating the public access to the roof. A Spa, studios and workplaces are connected by stairs and ramps. Figure 6 also illustrates sketches of the circulation approach of both interior and exterior urban stairs and their various functions targeting both specific users or public at large.

Figure 7 illustrates the different plans of the project and their levels within the site. The ground floor plan is open to the public so that one can pass through the project from one street to the parallel street. There are diverse functions accommodated on each floor or atop of the roof of each floor; the internal spaces have diverse functions like exhibition halls and working spaces. Figure 6, 7 & 8 illustrate the idea of connection and urban stairs. The sections through the different levels, both urban stairs and internal and external stairs allow a continuous circulation connecting the ground floor, to the roof, where the user can either access the project functions, cross to the other street or move from one space to another.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 7. Plans of the different levels of the project within the site

In Figure 8, the different sections display the courtyard where its primary purpose is to match the urban typological tissue, but it also hosts the circus performance in the project, which is one of the permanent outdoor functions. As mentioned before, permanent and temporary programs are found both in the centre and around the circulation on the stairs. These diagrams and sections illustrate public access from the ground floor, through the circulation on the exterior stairs to the roof, for both the general public and the local community. On the other hand the interior spaces are specifically targeted for certain users; as shown in Figures 7, 8 and 10.

The selected material for the facades is glass panels with divisions of concrete to reflect people's interactions and experience the different elements of the exterior spaces. To summarise, the project's design and content are for temporary and permanent events, with functions and programs accommodating the needs of diverse users and the local community, while creating a new view to Madrid from the rooftop to view and enjoy the city. The created active connection between the two parallel streets will also enhance and empower the cultural significance of the urban tissue.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 8. Different sections of the project building

Finally, Figure 9 illustrates a schematic representation of the facade elevation of part of the street in the project area. So, this building, although it does not match the same morphological facades style, matches the same integrity of the typological urban tissue of the area.

Figure 9. Schematic illustration of the facade elevation of part of the street in the project area

Figure 10 illustrates different shots clarifying the process of developing the project's final image and primary material (glass and concrete).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 10. different shots showing the process of developing the final image and primary material (glass and concrete) of the project

Therefore, to enhance the visual image of the historical cores, the task of architects and planners is not only to preserve prominent elements, particularly the façades of some historical settings and adapt them to imitate the more positive aspects of modern life but also to preserve the integrity values and the community collective memory while upgrading the elements to fulfill their modern life standards and expectations. Also, creating green landscapes as public outdoor open spaces to help the local community and enhance pedestrian connectivity are critical and essential issues for the infill action plans.

However, "the image of an existing building or historic centre is not static but is constantly subject to changes" (Philokyrou, 2015, p. 11). Where structure replacement is required, as it sometimes is, on structural or health grounds or both, this should agree with the existing character of the units. In infill projects, replacement buildings must be of proper scale (See Figures 9 and 10); otherwise, the units will miss their identity if the street lines remain unchanged (Whitehand et al., 2011). In addition, the characteristics of the selected places should be thoroughly analysed. Accordingly, their specific characteristics should be established by respecting their role in the traditional context (Dincyurek and Turker, 2007).

To conclude, a compatible and sustainable use of the historic core is only possible by filling these historic cores with its complete role "as a place of socio-economic and cultural creation, shared enjoyment, and memory; as a leading strategy" (Haddad and Fakhoury 2016, p.49). On the other hand, as the historic urban area continues to grow, as will the related financial, socio-cultural, and other problems, treating the physical manifestation of such problems as also the infill approach in isolation increases the danger that the impact of a conservation policy will conflict with local needs, expectations, or resources (Steinberg, 1996; Haddad and Fakhoury, 2016).

4. CONCLUSION and RECOMMENDATIONS

In the framework of the above discussion of the problematic aspects of infill projects, the adapted practices and policies in the Chueca area in the heart of Madrid and the imposed effects on the heritage sites, it will be beneficial to point out some recommendations and solutions. Infill design projects in the historic core can show a genuine role as an emerging place of interactions between the modern fabric site and urban heritage locations. The paper presents some of those ideas to improve the urban system in the study area in a sustainable way that balances the protection of the existing heritage and the sufficient planning of the modern urban area. A vital issue to be considered in the infill projects and urbanisation centres, as in the case

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

of this paper, is to ensure that any development near such sites is under control and to minimise the negative impact of negative modern infill and out of scale structures. A balanced cultural and urbanscape system can be obtained to integrate better heritage and modern infills in cities.

Any new development plans must provide sufficient open spaces in high-density urban heritage areas for green and outdoor spaces, parking areas and other essential uses. There is a need to raise the total of outdoor open spaces in the urban system to balance the environmental system for a socially sustainable environment. The presence of empty open spaces or neglected constructions in inward and inner block locations through the study area, accessed through indirect paths within the historic city blocks, has the potential to create public open spaces or enclosures within the blocks as illustrated in the design of this Chueca proposed project, where creating an urban connection between two parallel paths or streets can enhance and empower the cultural significance of the urban tissue.

This can strengthen the quality of life in the heavily historic urbanised quarters and initiate new places of interest for residents and tourists' routes and activities (Haddad and Fakhoury, 2016, p. 49). In this sense, the potential of the redesign of elapsed urban spaces is outstanding: "Covered spaces offer new opportunities for regenerating a city, engaging in new relationships, building new squares, and activating new, unexpected connections between the different parts of a city" (Cherchi, 2015, p. 257; Haddad and Fakhoury, 2016).

Finally, digital analytical tools and socio-cultural concepts can enrich and enhance the conventional infill methods utilised in such sites to ensure the social sustainability of urban settings and their authenticity, integrity and cultural significance, such as GIS, digital mapping systems, and AI that could link spatial and non-spatial data of the typological and morphological aspects of structures and landscape features to assist in recommending of how to deal with the different urban features, besides their role in 3D modeling the infill urban process and its effects on the heritage urban fabric. Meanwhile, combining public participation in integrated conservation and planning policy should benefit all parties (Yung and Chan, 2011).

Acknowledgements:

The efforts taken in compiling this research would not have been possible without the kind and extensive support and cooperation of Dr. Juan Cabello Arribas from IE University and, latterly, Professor Dr. Naif Haddad. I want to express my deep, sincere thanks to them.

ABSTRACT

This research paper focuses on the restoration, presentation and preservation of Hisban; an archaeological site in Jordan, while integrating local community involvement and adopting sustainable tourism practices. The project aims to protect both the tangible and intangible heritage assets of Hisban by developing a sustainable tourism attraction that showcases the site's rich interconnected layers. By reusing buildings from the Ottoman era and infusing new meanings into the existing spaces, a comprehensive narrative is created, bridging the past into the present. The project recognizes the significance of the local community identity, particularly as farmers deeply attached to their heritage. The proposed sustainable tourism attraction aims to meet the demands and needs of the local community, while fostering positive interaction between the community and visitors. The research explores strategies for adaptive reuse, spatial understanding of open spaces, restoration of existing façades, and interpretation displays within the buildings. Additionally, the project incorporates hiking trails that expand the visitor experience to encompass the hydrological and agricultural values of the area and its surroundings. Phased implementation allows for the adaptive reuse components to generate funding for subsequent stages, supporting the sustainable development of the community and the heritage site. The project emphasizes the use of sustainable materials, light interventions, and the preservation of the present narrative of the local community. Through its holistic approach, the research paper presents a comprehensive plan for transforming Hisban into a community-engaged tourist destination, preserving its heritage and fostering local identity and facilitating interactions between visitors and the local community.

Keywords: Sustainable Tourism, Heritage, Archeology, Local Community, Adaptive Reuse, Jordan, Agriculture, Hisban.

1. INTRODUCTION

Discovering Hisban's Rich Heritage

The project unfolds within the quaint village of Hisban, nestled on the outskirts of Jordan's capital, Amman. Hisban serves as a pivotal nexus connecting Amman and Madaba, boasting a landscape adorned with predominantly single or double-story buildings. Rooted in history, Hisban has a deep association with agriculture and farming traditions, characterizing its essence throughout the ages.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Central to Hisban's historical tapestry is its archaeological site, spanning from the late Bronze Age to modern times. This archaeological treasure is currently under excavation by Andrews University, known as the Hisban Archaeological Park and in cooperation with the Department of Antiquities. Within its precincts stand vestiges of a Byzantine church, a Roman temple, a Mamluk palace, and an Iron Age reservoir. Moreover, the village harbors numerous archaeological sites awaiting comprehensive excavation. Notably, Hisban once served as the capital of "Belqa" during the Mamluk era, emerging as a pivotal hub in the sugar trade industry during that epoch. The timeline is visually represented in Figure 1. (*Madaba Plains*)

The revelation of an Iron Age reservoir has drawn our focus to the hydrological dimension of this site. Extensive research has unveiled the presence of multiple cisterns, reservoirs, and water wells in the vicinity. Adjacent to the site flows a stream coursing through the valley, linking Hisban to Seil Hisban, the Jordan River, and culminating at the Dead Sea (Jones, 2003).

The zenith of Hisban's prosperity manifested during the Byzantine period, marked by the construction of three churches of profound religious significance. Notably, a bathhouse emerged on the western fringes of the church, crowning the archaeological site's summit. Remarkably, water systems from antecedent civilizations, such as the Iron Age reservoir and Roman cisterns along the plateau, continued to serve the community during this era (Jones, 2003).

In the Abbasid period, Hisban played a pivotal role in the Green Revolution, introducing over 20 new floras to the region and implementing crop rotation practices. The swift adoption of these agricultural innovations hinged on the sustainability of the water systems inherited from prior civilizations. The preservation and adaptation of these systems underscored their critical importance in sustaining these transformative processes (Jones, 2003).

During the Mamluk period, Hisban underwent refortification and ascended to the status of the capital of "Belqa." It assumed the role of safeguarding the Mamluks' economic interests as a lucrative agricultural epicenter, supplying provisions to pilgrims on route to holy sites and mediating complex political affairs. Moreover, it served as a prominent distribution center for the sugar trade industry, seeing the passage of trade caravans laden with diverse commodities (Jones, 2003).

The Ottoman period bore its share of tribulations for Hisban, yet in 1889, a resurgence occurred with the reconstruction of mills in the Jordan Valley and Palestine. This era witnessed the construction of several enduring edifices, a subject elaborated upon in the later sections of this research paper (Jones, 2003).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

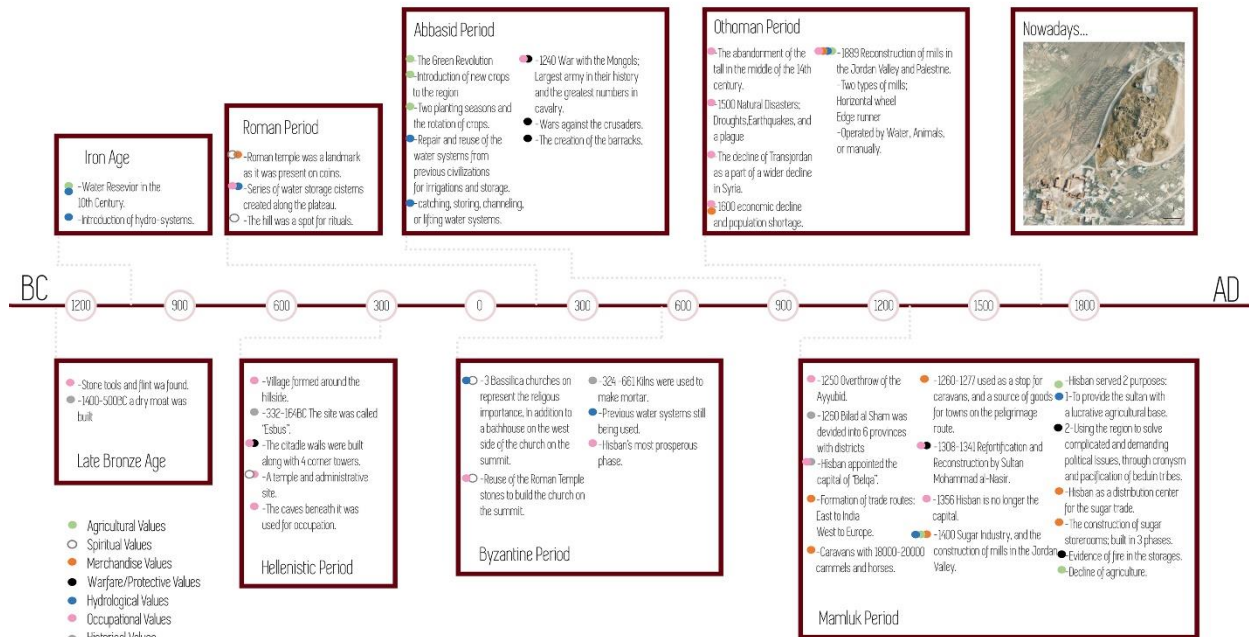

Figure 1. Detailed timeline of Hisban. (Madaba Plains)

Project and Community Context

-Local cultural assets:

Hisban is a very well-known agricultural village located on the southern outskirts of the capital Amman. The location forms a node that connects two cities: Amman and Madaba. Also, it is close to the airport. (Madaba Plains)

The archaeological site is on the village's highest summit which gives a clear undisturbed view of the valley on its west.

The local community was noticed to have a great interest in horses and horse riding, which dates back to distant history within the region.

The local village is occupied by mainly 3 families. The locals are very friendly and approachable people. Who are used to receiving visitors in their village, since Andrews University excavations take place annually within the village. (Madaba Plains)

Site Selection and Existing Buildings

The site selected for development and interpretation was the zone holding the Ottoman buildings, where protecting those buildings will help preserve part of Hisban's history. The Zone shown in figure 2 contains several buildings. The buildings' physical condition had to go through an assessment to create an appropriate understanding for the proposed interventions.

Ottoman Complex and Heritage Assessment

In this section, an overview of the Ottoman complex at the archaeological site is provided. Specifically, the focus will be on the eastern and western sections of the courthouse, the stables,

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

the Mamluk tower, a family house and Al-Qasr, where an evaluation of the historical and architectural significance of these structures was conducted.

Courthouse: Eastern Wing. The eastern part of the courthouse served as a guest house and currently includes a storage area to accommodate local farmers' agricultural tools. Evidence shows that the eastern and western parts of the courthouse were connected. The structure of the roofs is constructed out of cross vaults, currently with a deteriorated interior. Notably, the eastern elevation and its extension showed signs of deterioration. Interestingly, the doors and windows have kept their structural integrity despite the internal deterioration (Carroll, Fenner, & Labianca, 2006).

Courthouse: Western Wing. Similar to the eastern wing, the western section of the courthouse was also designated as a guest house and included a storage unit. Here, the detachment of architectural elements is more prominent, along with well-preserved stairs. Once again, the doors have withstood the test of time, while signs of detachment from the eastern part are more evident (Carroll, Fenner, & Labianca, 2006).

Stables: The stables were designed to house horses, with a dedicated circulation area and storage space for food and utensils. Our assessment reveals a structural failure in the ceiling, added at a later date than the original construction. Intriguingly, the eastern wall displays extruded arches, suggesting an earlier origin than the stables themselves linking these arches to the tower towards the south. Moreover, the western elevation exhibits a distinct craftsmanship compared to the other facades (Carroll, Fenner & Labianca, 2006).

Mamluk Tower and Citadel: The Mamluk tower served as a protective structure and is regarded as the oldest building in the vicinity. Nearby, remnants of a citadel were also identified. Supporting evidence, including the presence of an underground room, which was uncovered in a 2001 study. Among the architectural features, a barrel vault was identified. Notably, the area has evolved over time, and the current remains present a freestanding wall. Further excavation may yield valuable insights (*Madaba Plains*).

Family House A family currently resides in this structure, which includes a storage facility from a bygone era. The building's physical condition remains sound, and it is presently used as shelter for chickens.

Al-Qasr: Al-Qasr appears to have undergone construction in three phases. The initial phase involved storage spaces, followed by a residential area above it. Subsequently, an extension, known as a 'madafa,' was added. Al-Qasr showcases distinct craftsmanship, with differences in the stone used in the original and 'madafa' sections. Internally, significant deterioration is evident, with some cross vaults having collapsed. Although several doors and openings maintain their integrity, others require attention. Currently, the interior serves as a communal space for animals and other purposes (Carroll, Fenner & Labianca, 2006).

Analyzing Spatial Values Through the Nara Grid

Subsequent to the comprehensive physical assessment, the application of the Nara grid methodology proved instrumental in elucidating the intrinsic values embedded within the designated zone. The values in our assessment included Historical, Ambient, Conceptual and Artistic. This analysis identified three principal outdoor congregation spaces, each serving distinct functions: spiritual activities, social interactions, and the hosting of celebrations and events. A visual representation is represented in Figure 3.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Notably, the community of Hisban presents unique sociocultural characteristics, exemplified by the prominent presence of horses within the village environs. These equine companions, frequently encountered during strolls through the village, serve as both essential modes of transportation to neighboring locales and indispensable aids in the cultivation of agricultural lands.

In the annals of Hisban's history, the year 1970 marked a significant juncture as Andrews University initiated archaeological excavations within this historically rich enclave. This pivotal undertaking fostered collaborative relationships between local Jordanian authorities and international educational institutions, signifying the inception of valuable partnerships that continue to shape the site's exploration (*Madaba plains*).

Figure 2. The result of the physical assessment.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 3. The Visual representation of the Nara Grid.

Site Appraisal & SWOT

The site offers a great opportunity to help the present village economy and save important buildings which played an important part of Hisban's heritage. The project also holds many interesting natural features which are explored in the design section of this research paper. Also, this selected site seems to hold the different layers of historic data-documentation to serve as an interpretation center. The SWOT revealed that the site can create a historic landmark. The SWOT analysis is shown in figure 4.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

SWOT Analysis	Strength	Weakness	Opportunities	Threats
Location	Naturally forms a node that connects to 2 major cities in Jordan. And its of very close proximity to the airport. <u>Also</u> VERY close to the main GJU campus in Madaba. Well established archaeological site with an extended area, that is connected to important routes.	The infrastructure of the area is not the best.	Using the Historic values of the area to ignite tourism. Bring in the students from GJU.	Not well known to the youth. Slippery roads during rainfall. Bad infrastructure.
Social	The community in the area are very friendly, and the families have a close relation with each other.	-Each "ashera" forms a closed community	Helping the local communities by involving them in the project.	On the lower end of the Socioeconomic scale.
Economy	The economy of the area comes from the government employment, and agriculture.	The site does not benefit from the historic layer of the area for revenue.	Creating a tourist attraction that can bring more income to the locals.	
Archaeological	Deep history, well documented site. From the iron age up until modernity	It's not a <u>well known</u> location.	Teaching about a new historic landmark that's not very well known.	Urban sprawl intervening on the historic structures.

Figure 4. SWOT analysis.

The Goal of the project is to protect the archeological site and the Ottoman Complex by disseminating information about the extended history of the area; gaining touristic recognition.

Objectives include:

- Develop the site as a sustainable tourist attraction point.
- Disseminating information about the historic layer of the area.
- Involving the local community and increasing their income; horse riders and farmers.
- Build on the farming potential in the area as part of agricultural tourism.
- Act as a catalyst for Andrews University's excavations.
- Achieve economical and energy sustainability.
- Increase the quality of the recreational image in the neighborhood.
- Link Between the Ottoman complex and the valley.

Market Demand Analysis and Building the Program

The functions of the project were selected based on their need in the area/region and for the project to run in a self-sustaining model. Additionally, they needed to fit within the concept of the project.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

The project's functions were introduced as a journey developed within the design phase. This journey started introducing the activities to the users and linking itself with the spaces on the site based on the values that each part projects. As shown in figure 5. Thus, the functions should reflect that information onto the visitor.

1-Accommodation Units

The number of visitors of multiple tourists' destinations were studied and the number of the Tourists by destination reached more than 100,000 international visitors annually. The aim was to pin the project on the trail. A weakness was identified in the number of hotels and accommodation units in Madaba, which necessitated that the project holds accommodation units. (Department of Statistics, 2016)

2- Visitor's Center

The visitor center was a crucial part of the project to enable the site to hold interpretations and be pinned as a tourist attraction point. This center also holds the interactive educational parts of the project, and gallery spaces.

3-Dighouse

This function will enable the site to become a catalyst for excavations with Andrews University. As the Madaba Plains Project that they are running does not have a specific space. Additionally, it will allow volunteers and locals to participate in the excavation process.

4-Community Stables

The stables will enable the locals to have access to food and equipment for their horses. Additionally, they can shelter them within. The horse riders can offer their services here to take tourists on hiking trials on the horses into the farmlands or to the water stream. Expanding the project benefits away from the village. The stables are also to include a vet to take care of the health of the horses.

5-Community Kitchens and Restaurant

The kitchen enables the international visitors to be introduced to food from our culture. By bringing them to the locals they can form together dialogues that will benefit the locals through the revenue from the restaurant.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Activity Based Program

Activity	Type of Activity	Facility	Function	Demand for Function	Targeted Users
Overnight Stay	Leisure, Necessity	Accommodation Units	Spaces to accommodate Andrew's University Researchers and Tourists.	Lack of accommodation in the region based on data from the department of statistics.	Researchers, International Tourists, Local tourists
Assisting Excavations	Educational, Social	Dighthouse	Studying, reconstructing and preservation of archeological findings.	A catalyst for Andrew's University excavations.	Researchers, Volunteers
Horse Riding	Leisure, Educational, Social, Necessity	Community Stables	A space to accommodate the needs of horses for the community, and riding activities.	Lack of important requirements for horses in the village.	Local Community, International Tourists, Local Tourists, Volunteers
Cooking	Educational, Social	Community Kitchens	Cooking and eating activities with visitors and the local community.	Providing food for the accommodation, and forming a dialogue between the locals and the tourists.	Local Community, International Tourists, Local Tourists, Volunteers
Learning the Values	Educational, Social	Visitor Center (Interpretation Center)	Interpreting the values of the historic events that occurred in the village.	The protection of heritage.	Researchers, International Tourists, Local tourists

Figure 5. Project program.

Project Statement

Providing a journey for the visitors with different interactions and types of exposure; creating a sense of identity and belonging through the phenomenology of a series of activities and experiences. Pinning the project as a tourist attraction.

Concept

Creating 2 main zones of interaction. The valley and the complex; holding different qualities. The valley will hold the memory of life, activating the senses of the user in multiple ways throughout different activities within an open green space. The complex will hold the memory of Age, presenting information about the site within a trial of enclosed humble spaces. The journey educates users about three main parts; History, agriculture, and sustainability. Through multiple interpretations of diverse types within the site.

Forces and Form Generator

Multiple elements of the site shaped the synthesis of the design. Which are shown in figure 6.

1- A module was created from the size of the cross vaults existing within the buildings. This module created a grid which was spread on the site. Modules from this grid created solids or voids that formed the circulation throughout the site. Simultaneously these modules became interpretation points or functional spaces.

2-Natural exposed bedrock on the edge of the valley was preserved and was a vital landscape element connecting the different buildings within the project.

3-Rainfall simulation was carried out on the edge of the valley, recognizing the points where water collected naturally, and the modules formed water storage tanks in those locations.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

4-Retaining wall chains were extended from neighboring farmlands into the site. Enabling a seamless transition within the landscape.

5-Urban sprawl of the village started to intercept the archeological site from multiple locations. The project aims to protect further expansion of the village into the archeological site's boundaries.

Form Generator - Forces Diagram

Figure 6. Form generation diagram.

Strategy and Parameters for Re-Use

Masses

- 1) Defining the volumetric understanding of the spaces through anastylosis.
 - Lost volumes; steel structure abstraction.
 - Collapsed vertical plains; steel structure and glass.
 - Partially collapsed vertical plains; building up the volumes.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Voids

- 1-Defining the edges where the buildings meet with the ground.
- 2-Leveling the topography to its original levels.
- 3- Interpretations on platforms created by the modules.
- 2) Restoration of the existing façade.
- 3) Interpretations within the buildings.
- 4) Light intervention with the ability to be reversable, due to the ongoing excavation process.

Synthesis

The proposed design includes two main zones: adaptive re-use zone and the expansion along the valley's ridge. The masterplan of the proposal is shown in figure 7.

Figure 7. Masterplan.

The journey starts at the re-use zone shown in figure 8. Circulating through the project, the user will be exposed to the different layers of the site through multiple interpretations as shown in figure 9.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 8. The proposed levels of intervention in the re-use zone.

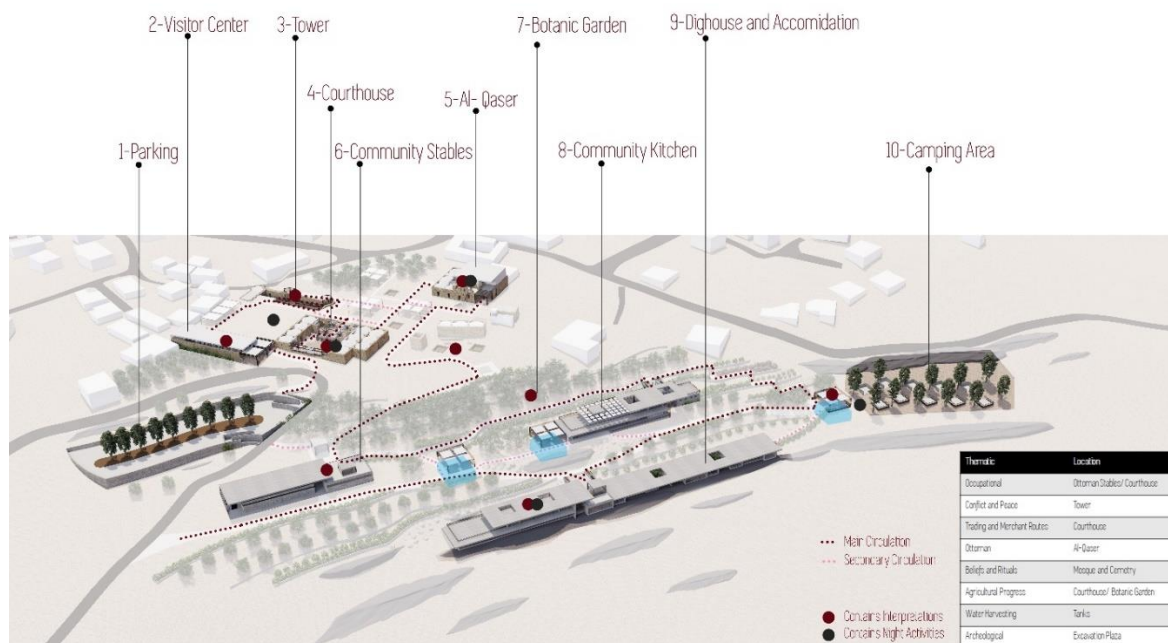

Figure 9. Proposed circulation and interpretation diagram.

Re-use Zone

-Visitors' Center: The initial steps included the demolition of a deteriorated roof and the addition of galvanized mesh for walkways and leveling. Additionally, the south facade required stone re-pointing to restore its structural integrity. Inside, an exhibition space was established,

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

with a portion accessible to locals for gatherings and ceremonies. The gathering area underwent minimal intervention to maintain its celebratory ambiance. The interventions are shown in figure 10.

-Mamluk Tower: Excavations will take place, revealing the barrel vault. The outdoor spaces took into consideration the ongoing excavation process; hence a steel ramp will take the users into the vault as it will host an exhibition space. Anastylis revived the lost volumes of the tower. The interventions are shown in figure 11.

-Courthouse: Abstractive anastylis was applied to the collapsed cross vaults and walls. Barriers obstructing openings were demolished, along with 20th-century interventions; storage units and concrete water tanks. This transformed the courtyard into a multifunctional space, serving as an exhibition area in the morning and an open-air cinema at night. A buffer was introduced to separate it from the street. Shaded seating areas were added. The shading devices' shadows mimicked the excavation grid, with visible traces of ongoing excavations elsewhere. The building includes two exhibition spaces and a small seed bank. The interventions are shown in figure 12.

-Al-Qasr: Extensive restoration efforts were undertaken, including the demolition of rubble walls, addition of galvanized mesh walkways, anastylis of the second floor, structural support additions, glass window installation, and the restoration of cross vaults and arches. Al-Qasr was reimagined as an exhibition space and multipurpose hall. The interventions are shown in figure 13.

Expansion Zone

Further down the valley, the landscape unfolds in distinct ways. To the east, the botanical garden is a close encounter with natural rock formations, fostering a tactile connection with geological elements. On the west, the panorama unveils breathtaking views, allowing visitors to engage with the surrounding landscape on a visual level. The pathways are constructed of a water canal that channels the rainwater captured into the water storage tanks created by the modules, that are topped with social seating areas.

The modules created the link to solve the leveling of the buildings on the ridge of the valley, they served as vertical circulation elements. And linking multiple functions within the same building.

-Community Stables: Staying on the planned route and user arrives at the roof of the stables. From there, they can see the horses through the slit between the two slabs and a part of the shop as an exhibition space formed from the module. Then they can directly enter the botanical garden without entering the stables. The design proposal is shown in figure 14. The stables will offer hiking trails for the visitors on horseback. Two routes were created for these hikes. The first explores the hydrological values of Hisban along the water stream. The second hike explores agricultural values through the farmlands.

-Community Kitchen: The user enters from the botanical garden into the terrace. Modules formed activity zones where the visitors can gather. Facilities in the southern part were included and can be used by campers in the camping zone. The design proposal is shown in figure 15 and figure 16.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

-Dig-house and Accommodations: Within this space, the workshop area comes into focus, providing insight into the activities and experiences of the researchers involved in the project. This area serves as a testament to the craftsmanship and dedication that went into the site's transformation. The design proposal is shown in figure 17.

At the same building we arrive at the accommodation area. The design of the accommodation hallway deliberately incorporates elements of the natural surroundings. It creates a semi-outdoor atmosphere, with features that frame the sky, permitting an infusion of natural light and the verdant hues of the adjacent greenery from the botanical garden. This approach ensures that occupants maintain a connection to the environment while experiencing the utmost comfort. The design proposal is shown in figure 18. Modules in this building created storage units for the workshops that function as display units simultaneously.

Figure 19. Proposed design of the camping area and the southern botanical garden.

Resource Analysis

-Capital cost:

The capital cost would be covered by a collaboration between the Department of Antiquities the Ministry of Tourism, and the Ministry of Agriculture, as the Municipality of Hisban would not be able to afford the potential costs of the project but can provide the workforce needed for the construction process.

-Running costs:

The vision included that the project would cover its own running cost by multiple revenue generating streams.

- 1-The ticketing
- 2-The accommodation
- 3-The restaurant
- 4-The stables

-Human Resources:

The project will have the capacity for providing new jobs, divided upon the staff of the accommodation units, restaurant and dining, tour guides, gardeners and horse keepers and the administrative parts. Whom will be employed from the local community.

Implementation Plan

The Project will be developed in 2 phases.

The first phase is the reuse part of the project. The second phase is the valley additions.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

The creation of the first phase of the project costs less than the second phase. This will enable the ticketing part of the project to open. Providing the revenue needed to build the second phase later. The first phase is fully functional and does not require the second phase to operate.

3.CONCLUSION

In the heart of Hisban, Jordan, a transformative endeavor has unfolded, aiming to breathe new life into the historical and cultural tapestry of this ancient village. As outlined in the abstract and introduction, the research presented here delves into the multi-faceted project that envisions Hisban as a thriving interpretation center and a hub for cultural exchange.

The journey embarked upon in this research has offered insights into the meticulous levels of intervention applied to rejuvenate a site bearing witness to over 3000 years of history. The visitor's center, the courthouse, the Qasr and the botanic garden, among other areas, have undergone extensive reimagining, from anastylosis efforts to structural support additions, all while respecting and preserving the historical significance of the site.

This project extends beyond physical restoration; it is an ode to community engagement, sustainability, and the preservation of cultural heritage. By involving local stakeholders and government bodies, the initiative not only ensures the sustainability of the center but also honors the heritage and memory of the land's previous occupants.

Moreover, the proposal exemplifies innovative design thinking, seamlessly integrating modern amenities with the natural landscape and historical structures. It fosters an enriching experience for visitors, offering a glimpse into the past while embracing the future.

In conclusion, the envisioned interpretation center in Hisban stands as a testament to the harmonious coexistence of heritage, community, and innovation. As this project progresses, it promises to serve as a beacon of cultural significance, educational enrichment, and economic revitalization, embodying the enduring spirit of Hisban and the enduring power of historical preservation. The journey undertaken in this research merely marks the beginning of a promising chapter in Hisban's storied history, as it continues to evolve and unfold, preserving the past while ushering in a vibrant future.

ABSTRACT

In today's rapidly evolving world, a knowledge society and an innovative economy are emerging. Investing in human capital has become more critical than ever as we face the problems of the twenty-first century, including pandemics, automation, and climate change. To properly address these difficulties, individuals' abilities and knowledge are crucial. Additionally, putting money into human capital can help create societies that are adaptable to future changes in demand. As it aids in reducing inequality and poverty, investing in human capital can result in the growth of a society that is more inclusive and equitable. The amount of human money influences how quickly economies, technologies, and sciences advance. More innovations in the fields of manufacturing and other connected activities result from increased human capital. Growth is increased by innovation. Adopting new technology is also produced through human capital. But economic expansion and the rise of human capital also have an impact on technology. In a new phase of economic development known as the knowledge economy, knowledge plays a key role and serves as a source of growth. Last but not least, investing in human capital is essential for sustainable development, which includes long-term advantages for people, businesses, and society at large. An environment that is favorable for the growth of human capital can be created by governments, businesses, and individuals. To invest in people and create a better, more sustainable future, everyone works together.

Keywords: Human Capital, Economic Growth, Technology, Innovation, Knowledge Economy.

1. INTRODUCTION

Human capital has been a concept since the eighteenth century. In his book "An Inquiry into the Nature and Causes of the Wealth of Nations", which examined a nation's wealth, knowledge, training, abilities, and experiences, Adam Smith made reference to the idea. Adams argued that enhancing human capital through education and training results in a more successful business, increasing the overall wealth of society. Smith claims that make it a win for everybody. The core component of the country's wealth is managed by human capital in the economy. Therefore, all scholars agree that human capital—which is more potent than nature or wealth—is the most crucial resource of the community.

The COVID-19 pandemic is changing the way we work and spend, including with highly uneven impact across people. The increase in digitalization could increase productivity. Amid the need to reduce in-person interactions, the pandemic has propelled investment in intangibles,

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

especially digital technologies, which has likely helped mitigate productivity losses stemming from measures to cope with the virus. The crisis can also affect the allocation of capital and labor across firms and sectors, with ambiguous effects on productivity. Skill gaps may present challenges. Some jobs vulnerable to automation or in contact-intensive activities may never come back, potentially triggering large job losses and requiring people to search for work in different sectors where new skills may be needed. Many people may face prolonged unemployment, eroding their skills and future productivity, and new entrants may face long-term lower earnings.

The development of the abilities required to support the operation and sustainability of an organization as well as to contribute to the welfare of societies and communities constitutes human capital, which is a crucial component of sustainability. Sustainability is not simply a check-the-box activity but rather a social, economic, and environmental factor that affects nearly every part of our existence. People are paying more attention to social concerns and sustainability now than ever before. Businesses are being compelled to take action and adhere to sustainability guidelines. A common transition framework for peace and prosperity for people and the earth, both now and in the future, is provided by the 2030 Agenda for Sustainable Development of the United Nations. The 17 interlinked Sustainable Development Goals (SDGs) - "the to-do list of the world" - are at the core of this agenda and aim to approach sustainable development holistically by targeting dignity, peace, and prosperity for the planet and humankind. In most countries, human capital determines the rate of development, economic, technological, and scientific progress. While providing stability for future generations and benefiting the entire world's population, sustainable development is not without difficulties. There are a large number of challenges that need to be met if we are to achieve a better future, like war and instability, suitability and availability, governmental issues, poverty & unemployment, population growth, and the global economy.

2. REVIEW of LITERATURE

Aqib, M., & Zaman, K. (2023), "Greening the Workforce: The Power of Investing in Human Capital", the role that human capital can play in accelerating economic growth is of interest to experts. Although some research has been done, more needs to be done on the topic of harnessing human capital to reduce carbon emissions in developing nations. Therefore, the study focused on how improving human capital can increase a nation's prosperity through enhancing environmental sustainability through labor-added technologies. By encouraging the development of cleaner industrial techniques, R&D spending and labor-augmented technology granger promotes life expectancy, which in turn helps improve the long-term viability of healthcare in a country. According to the conclusions of the innovation accounting matrix, during the next ten years, the two most important human capital determinants affecting carbon emissions will be life expectancy and the net enrolment rate. In addition to human capital, the green development agenda is also impacted by changes in the labour market, spending on research and development, and technology that makes work easier.

Natalya Guz and Margarita Kvashnina (2022) "Human capital and the knowledge economy as key challenges of post-industrial society", human capital, the foundation of both social and intellectual capital, is evolving from just being a factor in competitiveness to becoming the main source of social prosperity. The development of fundamentally altered economic relations and production relations against the backdrop of economic globalization is intimately related to changes in social and labour relations, particularly in employment models. The challenges

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

associated with the formation and growth of human capital in the modern world stem from the fact that, on the one hand, people develop the most cutting-edge systems, including technology, technological knowledge, high-tech production methods, and market opportunities, which must be effectively and thoroughly managed.

Suryaning, Bawono. Eny Lestari, Widarni. (2021), "The Role of Technology in Human Capital and Economic Growth in Indonesia", both indirectly and directly influencing economic growth, technology plays a part in boosting the impact of human capital. But economic expansion and the rise of human capital also have an impact on technology. Economic expansion, technology, and human capital all have mutually beneficial effects.

3. OBJECTIVES of THE STUDY

1. To study about human capital and technology in sustainable development in global perspective.
2. To know the various roles of Human Capital and Technology in Driving Sustainable Development.
3. The impacts of technology in sustainable development
4. To study the various advantages and futures of technology in sustainable development.

Human Capital and Technology

Human capital is considered an organization's most important asset because, without humans, there will not be anyone to sell the company products or services, manage the company's daily operations, or handle customers effectively. Any organization will only be able to go as far as the people who are driving it. Human capital in the technology industry is a new form of human and social capital based on the accumulation of knowledge linked with the new information communications technologies. Modern economies and society are evolving in large part thanks to Information and Communication Technology (ICT). Human capital, creativity, and technology are the main propellers of a knowledge economy. This entails the creation and application of cutting-edge technology, the expansion of highly educated and skilled labour, and the encouragement of research and development with a focus on entrepreneurship and innovation.

Human capital, creativity, and technology are the main propellers of a knowledge economy. This entails the creation and application of cutting-edge technology, the expansion of highly educated and skilled personnel, and the encouragement of research and development with a focus on entrepreneurship and innovation. Because it fosters economic growth, social advancement, and environmental sustainability, human capital investment is a crucial component of sustainable development. By maximizing needed skills through employee recruitment, training, and development, human capital management (HCM) refers to workforce practices and resources. Administrative assistance, reporting and analytics, education and training, and hiring and recruitment are frequently handled by departments and software programmes with responsibility for human capital management.

Human Capital and Sustainability

The four pillars of sustainability are social, environmental, economic, and human. Human capital is integral to sustainability and involves the acquisition of the necessary skills to support the functioning and sustainability of an organization and to contribute to the well-being of societies and communities.

Figure 1. The four pillars of sustainability

Roles of Human Capital and Technology in Driving Sustainable Development

Human capital investment is an essential element of sustainable development, as it promotes economic growth, social advancement, and environmental sustainability.

Human Capital Development

Education and Skills: Investing in education and skills development enhances human capital. An educated and skilled workforce is more adaptable to technological changes and can contribute by driving innovation and productivity. **Healthcare:** Access to quality healthcare ensures a healthy workforce. Healthy individuals are more productive and can actively participate in economic activities, reducing the burden of healthcare costs on society.

Technology and Innovation

Environmental Sustainability: Technology can be harnessed to develop cleaner energy sources, reduce pollution, and mitigate climate change. For instance, renewable energy technologies like solar and wind power promote sustainability by reducing greenhouse gas emissions. **Efficiency and Productivity** Technological advancements improve production processes, reduce waste, and increase efficiency. This can lead to sustainable resource use and lower costs for businesses. **Access to Information:** Technology facilitates access to information, education, and markets. This inclusivity can empower marginalized communities, bridging economic disparities and promoting social sustainability.

Economic Growth

Innovation-Driven Growth: The synergy between human capital and technology drives innovation, which fuels economic growth. Sustainable economic development is characterized by diversification, reduced income inequality, and resilience against economic shocks. **Job Creation:** Technological advancements create new job opportunities, particularly in emerging

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

sectors like renewable energy, biotechnology, and digital industries. These sectors often prioritize sustainability in their practices.

Global Connectivity

Knowledge Sharing: Technology facilitates global knowledge sharing, enabling countries to learn from each other sustainable development experiences. **Trade and Collaboration:** Technology connects global markets and fosters international collaboration on sustainability initiatives.

Monitoring and Evaluation

Data and Analytics: Technology provides tools for monitoring and evaluating sustainable development goals and initiatives. Data-driven insights help governments and organizations make informed decisions and track progress.

4.CONCLUSION

Human capital sustainability also requires ensuring that leadership is effective, that a company's human capital strategy is aligned with business strategy; that an organization has a healthy company culture, and that two key facets of human capital program design and delivery are preserving and creating value: Operational excellence, which focuses on achieving the optimal mix of people, processes, and technology. Talent experience focuses on how purpose, people, work, and total rewards combine with culture and leadership. Human capital development and technology are intertwined drivers of sustainable development. They empower individuals, businesses, and nations to address environmental, social, and economic challenges while fostering long-term prosperity and well-being for all. Human capital provides the knowledge, skills, and creativity to develop and implement sustainable solutions, while technology enhances productivity, enables innovation, and facilitates the monitoring and management impacts. Together, they drive progress toward a more sustainable and equitable future.

ABSTRACT

Designing a hydrological cycle model on Earth is the process of creating a simulation that replicates the water cycle stages, including evaporation, condensation, flow, and exchange within the natural environment. The model is constructed using various components, including the framework system, misting system, power supply unit, water pump motor, light bulbs, hot and cold reservoirs, cooling system, and other auxiliary components. An interactive model is designed to illustrate the phases and relationships among the water cycling processes in nature. Constructing a comprehensive model and designing teaching processes based on it has illustrated how water transitions through different states and interacts with the surrounding environment. Through interactive activities, students can observe how water impacts climate, topography, and ecosystems. Applying this practical model in an educational environment helps students understand the intricate process of water movement through different stages such as evaporation, condensation, and precipitation; enhance students' understanding of environmental science, hydrology, and the pivotal role of water within the Earth's ecosystem. Furthermore, educators leverage this model to employ a visual and interactive teaching approach to convey the significance of water conservation and sustainable practices. This method facilitates students' accessibility to complex scientific concepts.

Keywords: Hydrological Cycle Model, Water Cycling Processes, Climate, Evaporation, Condensation.

1. INTRODUCTION

Engineering science is the field of scientific disciplines related to the development of technology and the design of products, incorporating the application of natural scientific knowledge. Among these disciplines, the application of science and technology in engineering research is indispensable. The advancement of engineering science encompasses all creative and systematic activities that contribute to the development of knowledge related to both the natural and societal aspects of human life, ultimately leading to the creation of novel applications. This has been a continuous and overarching mission in the process of Vietnam's educational development, receiving significant attention and guidance from the government and the Ministry of Education and Training, particularly in the era of integration and Industry 4.0. Within educational institutions, research and the integration of scientific knowledge into teaching practices have also been of special concern during the fundamental and comprehensive educational reforms.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Many countries around the world are interested in and promote the development of experiential education to provide students with real-world experiences and the application of knowledge within an educational environment. Learners engage in hands-on activities using models that simulate physical processes or scale-down phenomena on Earth. The approach to and emphasis on experiential education may vary based on a country's culture, educational system, and specific goals. A common feature of global education is the focus on establishing laboratories, research centers, and modern learning facilities equipped with advanced technology. Nevertheless, not every country is able to meet these requirements (Pham, M. H., 1989).

Since the 1960s, the Learning Pyramid has become popular in the United States as a means of identifying the most effective learning methods. The Learning Pyramid illustrates the level of knowledge absorption by learners through various methods. The pyramid is divided into two parts: Passive Learning and Active Learning.

Figure 1. Learning Pyramid (Wood, 2004)

Through the learning pyramid, we can observe that we can remember only 5% of what we have heard during lectures, 10% when reading, but can recall up to 30% when visual aids are used in teaching.

To achieve effective teaching and learning outcomes, there are fundamental requirements that must be met in the teaching process, particularly when it comes to the subject of Geography in high schools. The efficient use and utilization of visual aids in teaching, especially in Geography, play a crucial role. Incorporating visual aids into Geography lessons is essential because it allows students to observe a small portion of the objects around them. Most of the objects, such as volcanoes, the Earth's internal structure, river systems, and water cycles, cannot be observed directly. Students can only visualize them through visual aids.

Models are small-scale representations of objects or phenomena, designed to reflect their characteristics. During the teaching process, there are many topics that students may find challenging to imagine. In such cases, building models becomes necessary, creating favorable conditions for students to understand specific phenomena in a concrete, accurate manner, and facilitating faster comprehension of the lesson.

Literature Review

Studies on the water cycle

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

The water cycle is the existence and movement of water on the Earth's surface, within the Earth, and in the Earth's atmosphere. Water on Earth is constantly in motion, transitioning from one state to another, from liquid to vapor and then to solid, and vice versa. The water cycle has been occurring for billions of years, and all life on Earth depends on it; Earth would undoubtedly be an uninhabitable place without water (*Anderson, Wilmouth, Smith & Sayres, 2012*).

The water cycle has no specific starting point, but we can begin with the oceans. The Sun drives the water cycle by heating the water in the oceans, causing it to evaporate into the atmosphere. The rising air carries water vapor into the atmosphere, where it encounters cooler temperatures, causing the water vapor to condense into clouds. Air currents transport these clouds around the globe, and cloud particles collide, combine, and grow, eventually falling to the ground as precipitation (rain). Precipitation in the form of snow accumulates as snowpacks and glaciers, which can store frozen water for thousands of years. In warmer climates, as spring arrives, snow melts and flows on the surface, sometimes leading to flooding. Most of the precipitation falls over the oceans or on land and, due to gravity, becomes surface runoff. Much of this surface runoff flows into rivers through river valleys in the region, with the main flow entering the oceans. Surface runoff, and some infiltrating water, collects and is stored in freshwater lakes. However, not all surface runoff flows into rivers; a significant amount of water infiltrates underground. Some of the infiltrating water is retained in the shallow subsurface and percolates back into surface water (and the oceans) as groundwater flow. Some groundwater flows out as freshwater springs. Shallow groundwater is absorbed by plant roots and then transpired through leaves (<https://vi.wikipedia.org/>).

According to Nguyễn (2005), water resources include the water in rivers, ponds, lakes, marshes, seas, oceans, as well as in the atmosphere and biosphere. In the Water Resources Law of the Socialist Republic of Vietnam, it is defined as, "Water resources include surface water, rainwater, groundwater, and seawater within the territory of the Socialist Republic of Vietnam." Water possesses two fundamental attributes: it can be beneficial, and it can be harmful. Water serves as the driving force for all economic activities of humans, but it can also pose unpredictable and significant threats to human life. Large floods, for instance, can cause casualties and, in extreme cases, can even destroy entire ecosystems.

A research document by author Nguyễn & Đặng, (2003) analyzed the relative proportions of various types of water on Earth. These proportions are depicted in Figure 2.

Figure 2. Water distribution ratio on Earth (Nguyễn & Dặng, 2003)

The studies focus on examining the role of water in society and the extent of its impact on the natural world and humanity. The majority of research designs serve production and business purposes. No studies on the application of the water cycle model in education have been found yet.

Research on the activities of the water cycle model on Earth

It is very difficult to accurately determine the exact amount of water on Earth, but through numerous surveys, calculations, and inferences, it is estimated that there is approximately 1.4 to 1.8 billion cubic kilometers (km³) of water on the planet. The water cycle is the existence and movement of water on the Earth's surface, within the Earth, and in the Earth's atmosphere. Water on Earth is constantly in motion, transitioning from one state to another, from liquid to vapor, and from solid to liquid and vice versa. The water cycle has been ongoing for billions of years, and all life on Earth depends on it; Earth would undoubtedly be an uninhabitable place without water (Nguyễn, Nguyễn, Nguyễn, & Nguyễn, 1991).

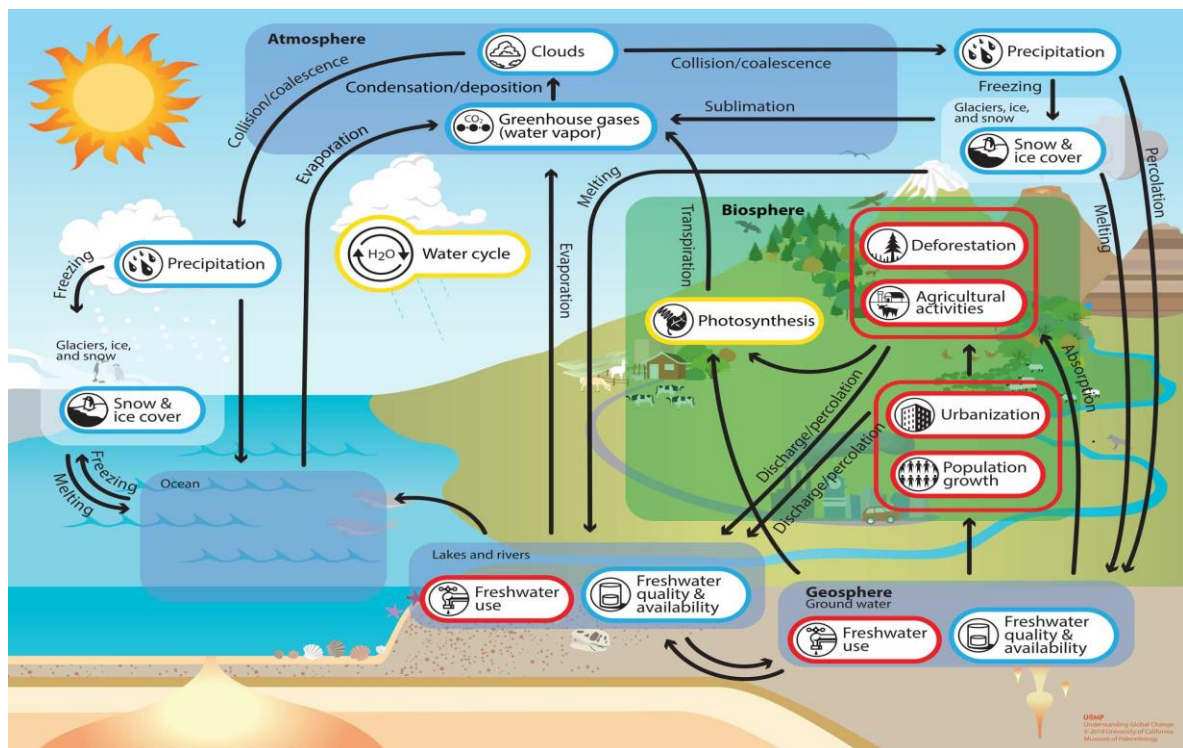

Figure 3. Earth system model of the water cycle (<https://ugc.berkeley.edu/background-content/water-cycle/>)

The water cycle model on Earth is simulated as shown in Figure 3. Therefore, water in reality exists in a closed cycle under the influence of natural conditions.

Research on teaching aids

The factors influencing the teaching process

There are three main factors that determine the quality of teaching: teachers, students, and teaching aids. These factors support each other as shown in the diagram below.

Figure 4. Correlation diagram between factors in teaching

Teaching aids are all the necessary material means for teachers and students to organize and conduct the educational process effectively and appropriately in various subjects and grade levels.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Teaching aids play an indispensable role in the teaching and learning process. The above factors interact and support each other. We can highlight some of the roles of teaching aids as follows:

- Is a teacher's working tool.
- Is a cognitive tool for students.
- Is the concretization of lesson content.
- Is the materialization of teaching methods.
- Contribute to promoting effective teaching and learning processes.

Thus, we can conclude that educational diversity is a factor closely linked to the pedagogical process, a measure reflecting the advancement and modernity of the learning environment in schools.

2. MATERIALS and METHODS

Designing a model of the water cycle on Earth and conducting experiments in teaching 10th-grade Geography aims to enhance students' comprehension of the lessons and generate enthusiasm during class. After designing the model, experiments were conducted, and the effectiveness of applying the model in teaching was evaluated.

During the research process, the author's team utilized various research methods, including: Theoretical research method; Modeling method; Empirical research method; Statistical analysis method.

3. FINDINGS and DISCUSSION

Design a water cycle model on Earth

The design diagram simulating the Earth's water cycle ensures all the natural elements are present to create a realistic model, making it easier for students to visualize in reality. Based on the diagram in Figure 3, prepare the appropriate materials for assembling a water cycle system in nature into a suitable model for the classroom.

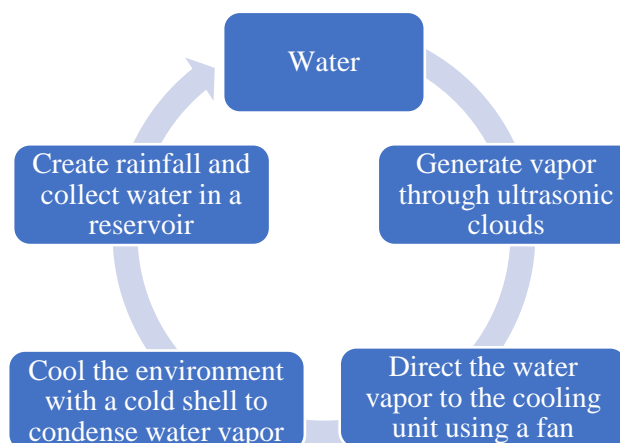

Figure 5. Rules of the water cycle in the model

When providing power to the system, the ultrasonic head immediately acts on the surrounding water, creating water vapor. The rising water vapor is directed into the chip peltier system to

TeMALab

September 14-15, 2023, Naples, Italy

undergo the condensation process. The cooled condensed water forms rainfall and is then collected in a reservoir, completing a water cycle.

Prepare equipment and tools

Prepare some equipment and tools as described in the table 1.

Table 1. Information and images of the components of the "Model" design

Component name	Purpose of use	Illustrating images
Physical model of rivers and mountains	Simulates mountains and rivers	
Mist generation system (Ultrasonic generator)	Creates mist to form rain	
Ultrasound power supply	Convert AC-220V voltage to DC-48V	
Power supply	Convert AC-220V voltage to DC-12V to supply fans, pumps, and coolers	
Light bulb	Symbolizes the Sun

Chip peltier

Condense water vapor

Mica frame shell system

Observe clearly inside

Mini pump

Use for pumping water

Flexible plastic tubes with a diameter of Ø8

Used for water conveyance

Mini fan

Used for suction of water vapor

Operation Principles of the Devices:

Mist Generation System (Ultrasonic Transducer): When power is supplied, the current directed to the transducer head is converted into high-frequency alternating current, which then emits ultrasonic waves through the humidifying orifice. Water in contact with the ultrasonic waves is atomized into a mist. This component is placed in a water reservoir.

Mini fan: The rising water vapor is directed by the fan to the cooling unit, which consists of two hot-cold modules and a metal heat-conducting block (we chose aluminum due to its cost-effectiveness and efficient heat conduction).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Chip peltier: The hot-cold module has two sides; when power is supplied, one side cools while the other side heats up. The cold side is fixed with an aluminum block for cooling and condensing water vapor. On the hot side, a water circulation system is used to cool the hot side by transferring water from the reservoir, preventing component damage.

The steps for designing a model

Step 1: Design the Mica frame

- Cut mica to size appropriate to the design table.
 - + 6 large mica panels for the box.
 - + Smaller panels are used to divide the box into multiple parts for each cycle, keeping components in different positions convenient for operation.
- Use glue to permanently attach the large mica panels to form the box.
- Attach smaller mica panels to partition each component and process.

Step 2: Install and fix the devices in the required position

- Mist generation system: Placed at the water tank, the lowest position of the system to stimulate the steam generation process.
- Mini fan: on the top floor, helps bring steam to the condensation area.
- Cooling area: Attach the cold side of the cooler to the metal block for heat dissipation and ease of installation. The hot side is attached to a cooling system that includes a water pump and a housing.
- Light bulb: Mounted on the wall of the system, representing the sun.

Step 3: Power up the devices

- Use 2 sources located at the lowest position of the system.
 - + Honeycomb source is used to lower the voltage from AC 220V to DC 48V for the ultrasound head.
 - + Source 2 reduces the voltage to DC 12V for cooling, fans, and pumps.

Step 4: Complete the product

Figure 6. Front and back view of the model

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Figure 7. The left and right sides of the model

Figure 8. The model while it is operating

Operating instructions

Step 1: Supply water to the device

Open the button on the top of the device, add water (normal filtered water) until it reaches the blue line on the device wall (or completely submerges the ultrasound head (Figure 6)).

Step 2: Power the device

Plug the device's power plug into the 220V source, turn the power button to ON

Step 3: Create clouds

Turn the ultrasonic steam generation button to ON,

Step 4: Create wind (air convection)

Turn on the fan button to create convection air towards ON.

Step 5: Observe the phenomenon.

Teachers and students can observe the natural water cycle phenomenon modeled in the device "Designing the Earth's Water Cycle Model: Applications in Education". Water on Earth under the influence of nature evaporates, is carried by the wind, condenses to form clouds, and meets cold air in the atmosphere to form rain... (Figure 3).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Experimental investigation of the model

We conducted product model testing on students from two high schools, with a total of 320 students participating in the experimental learning on the model. We had the students operate the model and observe the phenomena, and then we distributed survey questionnaires to assess the results.

Table 2. Situation of students participating in learning with the model

Survey subjects	Students' comments				Percentage of students who enjoy learning through the model	
	Have learned		Never studied		Total	
	Number of students	%	Number of students	%		
Class 10/1	2	4,76	40	95,24	97,62	42
10/2	3	6,98	40	93,02	97,67	43
10/3	7	17,50	33	82,50	97,50	40
10/4	10	24,39	31	75,61	95,12	41
10A3	4	19,05	17	80,95	95,24	21
10A4	6	26,09	17	73,91	100,00	23
10A5	2	12,50	14	87,50	93,75	16
10B1	0	0,00	33	100,00	100,00	33
10B2	4	13,79	25	86,21	100,00	29
10D1	2	6,25	30	93,75	100,00	32
Total	40	12,50	280	87,50	97,81	320

With a total of 320 students questioned, 313 students, accounting for 97.81%, wanted to study in combination with the model. This shows that there needs to be improvements in education to ensure the needs of learners. Learning theory combined with visual models helps students easily understand the lesson, remember it for a long time and understand the issues in the teacher's lecture content.

The level of response of the model in learning is shown in Figure 9.

Figure 9. The level of response of the model in learning

The favorable and very favorable opinions account for 87.8%, which is a relatively high proportion. At the same time, there are many opinions that the "Model" has many advantages such as: it feels very enjoyable, clearly illustrates phenomena, accurately reflects reality, is vivid, useful, enhances students' interest, makes knowledge easier to remember, and encourages creativity... Teachers and students highly appreciate both scientificity, creativity, pedagogy and aesthetics, practicality and effectiveness.

4. CONCLUSION and RECOMMENDATIONS

The project "Designing the Earth's Water Cycle Model: Applications in Education" has provided students and teachers with a visual tool for teaching and learning. The research results, which were tested, have shown a high effectiveness rate, with 97.81% of students expressing a strong liking for learning with this model. The authors also developed a set of multiple-choice questions to evaluate students' knowledge after experimenting with the model, the results are shown in Figure 10.

Figure 10. Learning outcomes for Geography lessons using models

The set of questions includes 6 questions moderated by the teacher in charge of the class, each question corresponds to 1 point. The results showed that 256/320 students answered all 6 questions correctly, accounting for 80.0%.

There are 4 classes 10/2, 10A5, 10B2 and 10D1 with 100% of students answering all 6 questions correctly, while class 10B1 has 51.5% of students answering 6 questions. 12.2% of 10th/4th grade students answered 2 questions. Thus, classes 10/4 and 10A3, 10A4 and 10B1 have the highest percentage of students answering incorrectly among the 10 classes, among them there are students who can only answer 3/6 questions and 2/6 questions.

With the research results obtained, we affirm that the project "Designing the Earth's Water Cycle Model: Applications in Education" has yielded very positive outcomes in supporting teaching activities in secondary schools. The research involved a comprehensive analysis of the theoretical foundation of the water cycle on Earth to better understand its principles. The

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

model's design accurately represents these principles, ensuring that the natural water cycle occurs as it should.

In particular, we conducted experiments with 320 students in Vietnam. Based on these results, we recommend that educational institutions consider the following when using the learning model:

- Utilize teaching materials that align closely with the curriculum content.
- Ensure that educational equipment and materials are integrated with textbook content.
- Adapt to the specific characteristics of each subject.
- Serve the purpose and requirements effectively, at the right time and place.
- Homemade teaching materials should be cost-effective while maintaining precision, scientific accuracy, and aesthetic appeal.

ABSTRACT

Preparedness in disaster response is a crucial aspect that cannot be overlooked. It involves the measures taken to mitigate the impact of disasters and ensure that communities are equipped to handle emergencies. Preparedness is essential because it enables individuals, organizations, and governments to respond effectively to disasters, save lives, and minimize damage. One of the key aspects of preparedness in disaster response is education. Communities need to be educated on how to prepare for disasters, what actions to take during an emergency, and how to respond after a disaster has occurred. This includes having emergency kits with essential supplies such as food, water, first aid kits, flashlights, and batteries. In addition to this, governments must have contingency plans in place for various types of disasters such as earthquakes or hurricanes. These plans should include evacuation routes for affected communities as well as shelters where people can seek refuge. Preparedness in disaster response is critical for saving lives and minimizing damage caused by natural calamities or other emergencies. It involves educating communities on how best to prepare for disasters; establishing effective communication channels; training personnel who can respond effectively during an emergency; and having contingency plans in place at all times. By taking these measures seriously the impact of disasters can be reduced on our communities while ensuring that people are better equipped to handle future emergencies when they arise. Emergencies and disasters can strike at any time and without warning. It is important to be prepared for such situations to ensure the safety of oneself, family, and community. This includes knowing evacuation routes, meeting places for family members, and having emergency contacts readily available. Being prepared for emergencies and disasters not only ensures personal safety but also helps communities recover more quickly from these events. It is recommended that, when individuals take responsibility for their own safety, they are less likely to require assistance from emergency services which frees up resources for those who truly need them.

1. INTRODUCTION

Preparedness in disaster response is a crucial aspect that cannot be overlooked. It involves the measures taken to mitigate the impact of disasters and ensure that communities are equipped to handle emergencies. Preparedness is essential because it enables individuals, organizations, and governments to respond effectively to disasters, save lives, and minimize damage. One of the key aspects of preparedness in disaster response is education. Communities need to be educated on how to prepare for disasters, what actions to take during an emergency, and how to respond after a disaster has occurred. This includes having emergency kits with essential supplies such as food, water, first aid kits, flashlights, and batteries. Another important aspect of preparedness is communication.

During a disaster or emergency situation, communication channels must be established so that people can receive timely information about what is happening and what actions they need to take. This includes setting up warning systems such as sirens or text alerts. Preparedness also involves having trained personnel who can respond effectively during an emergency. This includes firefighters, police officers, medical personnel, and search and rescue teams among others. These individuals must have the necessary skills and equipment needed for their roles. In addition to this, governments must have contingency plans in place for various types of disasters such as earthquakes or hurricanes. These plans should include evacuation routes for affected communities as well as shelters where people can seek refuge. Preparedness in disaster response is critical for saving lives and minimizing damage caused by natural calamities or other emergencies. It involves educating communities on how best to prepare for disasters; establishing effective communication channels; training personnel who can respond effectively during an emergency; and having contingency plans in place at all times. By taking these measures seriously we can reduce the impact of disasters on our communities while ensuring that we are better equipped to handle future emergencies when they arise.

Steps to Take to Prepare for Emergencies and Disasters

Emergencies and disasters can strike at any time, leaving individuals and communities in a state of chaos and confusion. It is essential to take steps to prepare for such events to minimize the impact they have on our lives. Here are some crucial steps that everyone should take to prepare for emergencies and disasters.

Firstly, it is important to create an emergency plan. This plan should include details about evacuation routes, meeting places, emergency contacts, and important documents that need to be kept safe. The plan should be discussed with all family members so that everyone knows what to do in case of an emergency.

Secondly, it is important to stock up on essential supplies. This includes food, water, first aid kits, flashlights with extra batteries, blankets, and other necessary items. It is also important to keep a supply of any medications that family members may need.

Thirdly, it is crucial to stay informed about potential emergencies or disasters in your area. This can be done by signing up for alerts from local authorities or downloading relevant apps on your phone.

Fourthly, it is important to practice emergency drills regularly with family members or co-workers if you work in a shared space. This will help ensure that everyone knows what they need to do in case of an actual emergency.

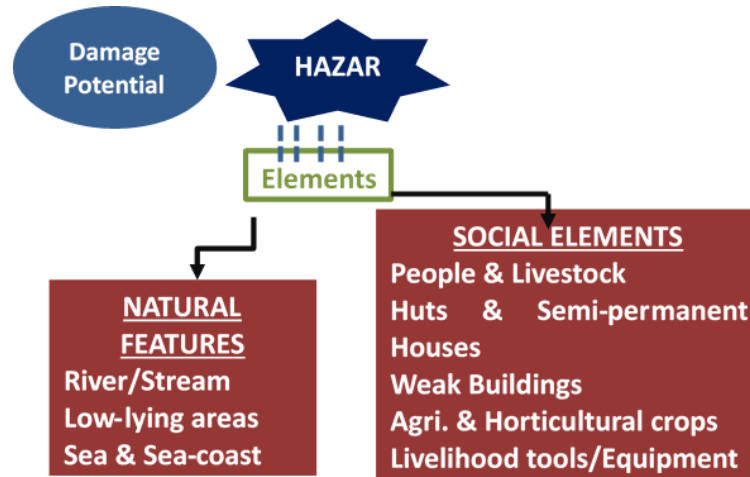

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Lastly, it is essential to have insurance coverage for emergencies or disasters such as floods or fires. This will help cover the costs associated with repairing damages caused by these events.

Importance of Being Prepared for Emergencies and Disasters

Emergencies and disasters can strike at any time and without warning. It is important to be prepared for such situations to ensure the safety of oneself, family, and community. Being prepared for emergencies and disasters means having a plan in place, adequate supplies, and knowledge of what to do in different scenarios. Having a plan in place is crucial when it comes to emergencies and disasters. This includes knowing evacuation routes, meeting places for family members, and having emergency contacts readily available. It is also important to have a communication plan in place so that everyone knows how to stay in touch during an emergency. Adequate supplies are also necessary when it comes to being prepared for emergencies and disasters.

This includes having enough food, water, medication, first aid supplies, and other essentials on hand. It is also important to have backup power sources such as generators or solar panels in case of power outages. Knowledge of what to do during different scenarios can make all the difference during an emergency or disaster. Knowing how to perform CPR or basic first aid can save lives while knowing how to shut off gas or water lines can prevent further damage from occurring. Being prepared for emergencies and disasters not only ensures personal safety but also helps communities recover more quickly from these events. When individuals take responsibility for their own safety, they are less likely to require assistance from emergency services which frees up resources for those who truly need them. In conclusion, being prepared for emergencies and disasters is essential for personal safety as well as the well-being of communities as a whole. By having a plan in place, adequate supplies on hand, and knowledge of what to do during different scenarios individuals can help mitigate the effects of these events on themselves and others around them.

Role of First Responders in Emergency and Disaster Response

First responders play a critical role in emergency and disaster response. These individuals are the first to arrive at the scene of an emergency or disaster, and their quick actions can often mean the difference between life and death for those affected. The role of first responders begins with preparation. They must be trained to respond quickly and effectively to a wide range of emergencies, from natural disasters like hurricanes and earthquakes to man-made incidents

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

such as terrorist attacks or industrial accidents. This training includes learning how to assess the situation, provide medical assistance, evacuate people safely, and communicate with other emergency personnel. During an emergency or disaster, first responders are responsible for providing immediate assistance to those in need. This may involve administering first aid or CPR, stabilizing patients for transport to a hospital, or rescuing people trapped in dangerous situations. They must also work quickly to evacuate people from affected areas and ensure that everyone is accounted for. In addition to providing immediate assistance, first responders also play a critical role in coordinating the overall response effort. They work closely with other emergency personnel such as police officers, firefighters, and paramedics to ensure that resources are deployed effectively and efficiently. This may involve setting up command centers or coordinating transportation for evacuees. One of the most important aspects of the role of first responders is communication. They must be able to communicate effectively with each other as well as with members of the public who may be affected by the emergency or disaster. This includes providing clear instructions on what actions people should take (such as evacuation orders) as well as keeping everyone informed about developments in the situation.

Finally, first responders also play an important role in recovery efforts following an emergency or disaster. They may assist with search-and-rescue operations or help provide basic necessities like food and water for those affected by the event. They may also work closely with local officials and community organizations to help rebuild damaged infrastructure or provide support services for those who have been displaced. In conclusion, the role of first responders in emergency and disaster response is critical. These individuals are responsible for providing immediate assistance to those in need, coordinating the overall response effort, communicating effectively with other emergency personnel and members of the public, and assisting with recovery efforts. Their quick actions and dedication can make all the difference in saving lives and minimizing the impact of an emergency or disaster.

Importance of Quick Response in Mitigating Damage from Emergencies and Disasters

Emergencies and disasters can strike at any time, leaving behind a trail of destruction and chaos. In such situations, quick response is crucial in mitigating the damage caused by these events. The importance of quick response cannot be overstated as it can make all the difference between life and death. One of the primary reasons why quick response is essential in emergencies and

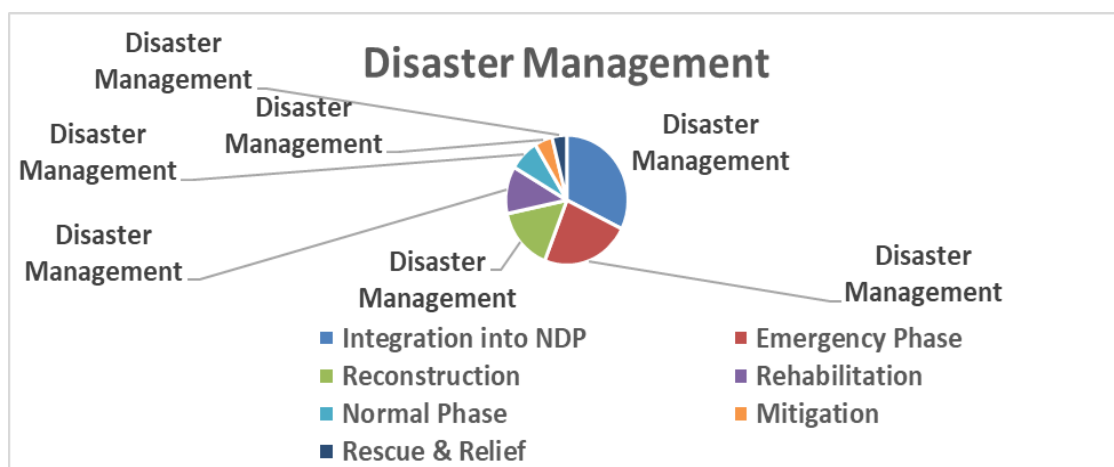

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

disasters is that it helps to save lives. When an emergency occurs, every second counts, and a delay in response can result in loss of life. For instance, during natural disasters such as earthquakes or floods, people may get trapped under debris or floodwaters. Quick response teams with specialized equipment can help rescue these individuals before it's too late. Another reason why quick response is vital in emergencies and disasters is that it helps to minimize property damage. Fires are one of the most common emergencies that occur worldwide, causing significant property damage each year. However, if firefighters respond quickly to a fire outbreak, they can prevent the fire from spreading further and causing more damage. Quick response also helps to reduce economic losses resulting from emergencies and disasters.

Disasters often disrupt economic activities leading to losses for businesses and individuals alike. However, if emergency responders act quickly to contain the situation, they can minimize economic losses by restoring normalcy as soon as possible. Moreover, quick response helps to restore order after an emergency or disaster has occurred. In many cases, emergencies lead to chaos as people try to flee or seek help. However, if there are trained responders on hand who know how to handle such situations efficiently, they can restore order quickly. In conclusion, quick response plays a critical role in mitigating damage from emergencies and disasters. It saves lives by providing timely assistance when needed most; minimizes property damage by preventing fires from spreading further; reduces economic losses resulting from disruptions caused by disasters; restores order after an emergency has occurred so that people can resume their daily activities without fear or anxiety. Therefore, it is essential to have well-trained and equipped emergency response teams in place to respond quickly to emergencies and disaster.

Significance of Emergency and Disaster Response

Emergency and disaster response is an essential aspect of any community's safety and security. The ability to respond quickly and effectively to emergencies can mean the difference between life and death, as well as minimize damage to property and infrastructure. In this essay, we will recap the importance of emergency and disaster response. Firstly, emergency response teams play a crucial role in saving lives during natural disasters such as hurricanes, earthquakes, floods, or wildfires. These teams are trained to provide immediate assistance to those in need by providing medical aid, shelter, food, water, and other essential supplies. Secondly, emergency response plans help communities prepare for potential disasters before they happen. By having a plan in place that outlines procedures for evacuation routes or communication

TeMALab

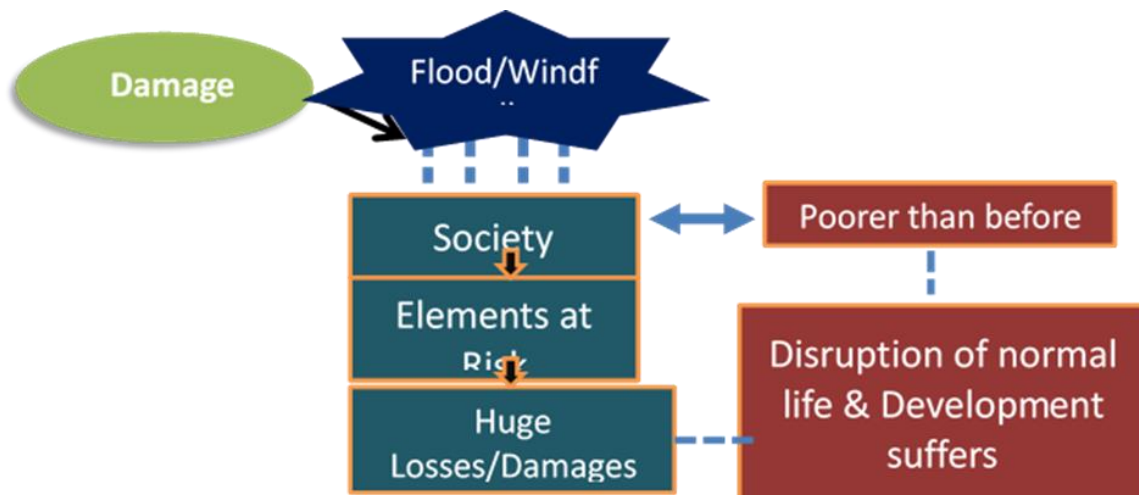

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

protocols between first responders and government officials can save countless lives. Thirdly, disaster response efforts can help mitigate the long-term effects of natural disasters on communities. For example, rebuilding efforts after a hurricane or earthquake can help restore infrastructure that was damaged during the event. Lastly but not least important is that effective emergency response efforts require collaboration between various agencies such as law enforcement agencies or fire departments. By working together towards a common goal of protecting citizens' safety during emergencies or disasters can ensure better outcomes for all involved parties. In conclusion, emergency and disaster response is an integral part of any community's safety plan. It is crucial to have well-trained first responders who are equipped with the necessary tools to respond quickly when needed. Moreover, having a comprehensive plan in place ensures that everyone knows what their role is during an emergency situation which ultimately saves lives.

Challenges of Emergencies and Disasters

The aftermath of such events can be overwhelming, both for the affected individuals and the government agencies tasked with responding to them. In this study, various challenges would be explored that arise in the aftermath of emergencies and disasters. One of the most pressing issues in the aftermath of an emergency or disaster is providing immediate relief to those affected. This includes providing shelter, food, water, medical care, and other essential supplies. The government agencies responsible for responding to these events must work quickly to assess the situation and provide assistance as soon as possible.

Another major challenge is restoring infrastructure and basic services such as electricity, water supply, telecommunications, transportation networks etc. These services are critical for people's survival and recovery from disasters. Rebuilding damaged infrastructure requires significant resources which may not be readily available especially in developing countries. The psychological impact of emergencies and disasters cannot be overlooked either. Survivors may experience trauma or PTSD which can have long-lasting effects on their mental health if not addressed properly. Therefore, it is important that mental health support is provided alongside physical support. In addition to these challenges there are also issues related to economic recovery after a disaster strikes. Businesses may suffer losses due to damage caused by natural calamities leading to job losses for employees which further impacts local economies.

Action forward

Emergencies and disasters can strike at any time, without warning. They can be natural disasters such as hurricanes, earthquakes, or floods, or man-made disasters such as terrorist attacks or industrial accidents. In any case, being prepared for emergencies and disasters is crucial to ensure the safety of individuals and their families. The first step in being prepared for emergencies and disasters is to have a plan. This plan should include an emergency contact list with names and phone numbers of family members, friends, and emergency services. It should also include a meeting place in case family members are separated during the disaster. Another important aspect of being prepared is having an emergency kit ready. This kit should contain essential items such as water, non-perishable food items, first aid supplies, flashlights with extra batteries, blankets, and a radio. It is also important to have a supply of any necessary medications on hand. In addition to having a plan and an emergency kit ready, it is important to stay informed about potential emergencies or disasters in your area. This can be done by signing up for local alerts through text messages or email notifications from local authorities. It is also important for individuals to take steps to protect their homes from potential damage during emergencies or disasters. This may include securing loose objects outside the home that could become projectiles during high winds or installing shutters on windows to protect against flying debris. Being prepared for emergencies and disasters not only ensures the safety of individuals but also helps reduce the burden on emergency services during times of crisis. By taking steps ahead of time to prepare for potential emergencies or disasters, individuals can help minimize the impact these events have on themselves and their communities. It is imperative that individuals take responsibility for their own safety by preparing themselves for potential emergencies and disasters. By having a plan in place, an emergency kit ready at all times, staying informed about potential threats in their area and taking steps to protect their homes, individuals can help ensure their safety and the safety of their loved ones. It is important to remember that emergencies and disasters can happen at any time, so being prepared is not only a good idea but also a necessity.

2. CONCLUSION

In conclusion, emergencies and disasters have far-reaching consequences that require a coordinated response from all stakeholders involved including governments at all levels (Local, State, Federal), non-governmental organizations (NGOs), international organizations like UN etc. It is essential that we learn from past experiences so that we can better prepare ourselves for future emergencies or disasters.

ABSTRACT

*The investigation of the Maastrichtian epoch in the Western High Atlas region reveals insights across biostratigraphy, lithostratigraphy, and paleogeography. The study emphasizes Echinoderm and ostracod identification. Notably, ostracods include (*Bythocypris gohrbandti* "Wesker 1968", *Ovocytheridea cf. producta*, *Cytherellia aff. gambiensis* "Apostolescu 1963", and *Paracyris* sp.), while the Echinoderm assemblage features *Petalobrissus subsetifensis* (Péron and Gauthier), indicative of the Maastrichtian. The correlation of Maastrichtian deposition sequences with third-order eustatic cycles confirms eustatic dominance in sedimentation. Nevertheless, tectonic activity was noted at the beginning of the Maastrichtian, causing abrupt variations in thicknesses associated with local subsidence and uplift. Synsedimentary faults and angular unconformities at the base of the Maastrichtian also indicate tectonic activity. Paleogeographically, the Maastrichtian marks an Atlantic transgression, resulting in the Erguita Basin being isolated from the phosphorus-rich Atlantic during the Campanian, while maintaining connectivity with the Imin'Tanout Basin through the Argana Corridor. In this work, we propose the hypothesis of openings in the Souss Basin to the*

Atlantic as a phosphorus source. The phosphate series demonstrates rhythmic sedimentation alternating between carbonate and phosphate-rich strata with organic residues. This reflects phosphatogenesis, associated with intense benthic activity in warm, shallow, well-ventilated environments. The end of the Maastrichtian shows a widespread regional discontinuity, witnessed beyond Morocco. This marks a global mass extinction concurrent with Late Cretaceous regression linked to the opening of the North Atlantic.

Keywords: Phosphate, Paleogeography, Maastrichtian, High Atlas, Morocco.

I. INTRODUCTION

Phosphates are highly coveted due to their phosphorus (P) content, a fundamental chemical element denoted as P in the realm of chemistry. Phosphorus serves as an indispensable constituent within the cellular structures of organisms, particularly humans. It plays a pivotal role in the construction of nucleic acids, namely DNA and RNA, as well as numerous enzymes (Corbridge, 2016). Its significance extends to the vital functions of energy storage and transfer within cells (Föllmi, 1996; Filippelli, 2011; Corbridge, 2016). In the animal kingdom, phosphorus manifests in the composition of bones and teeth, while in the plant domain, it assumes responsibility for the transmission of energy harnessed through photosynthesis.

Phosphorus, as an inherent substance, pervades our environment ubiquitously. Its presence is encountered daily, from the toothpaste employed in morning routines to the constituents of various food items (dairy, eggs, meats, fish, vegetables, and dried fruits). It forms the foundation of select pharmaceutical products and finds applications in diverse domains, including animal nutrition, detergent production, food preservation, and various other industrial pursuits.

Mineral phosphates assume paramount significance primarily in the realm of soil fertilization. These compounds serve as crucial fertilizers, with a substantial majority (85%) of global production devoted to enhancing soil fertility.

In the right proportions, phosphorus fosters root development in plants, augments their nutritional uptake, and enhances their resilience against diseases. These virtues culminate in augmented crop yields, both quantitatively and qualitatively, underscoring the indispensable role of phosphorus in agricultural productivity and, by extension, human nutrition.

Phosphorus extraction can be sourced from three distinct categories of phosphate deposits:

1. **Magmatic-Origin Phosphates:** Constituting 25% of the world's phosphate output, these deposits are associated with alkaline intrusive complexes.
2. **Guano Deposits:** These deposits, contributing 5% of the world's phosphate production, possess relatively smaller reserves but remain of significance.
3. **Sedimentary Phosphates:** Accounting for a substantial 70% of global production, these deposits are the most widespread and voluminous. They form in continental margins and epicontinental seas where water-sediment interfaces are subject to periodic or occasional reworking (Baturin, 1982; Glenn et al., 1994; Föllmi, 1996; Pufahl & Groat, 2017). The formation of sedimentary phosphates is contingent upon upwelling currents, which play a pivotal role in supplying the sedimentary environment with phosphorus, silica, and fluorine.

Fig 1. Map depicting the spatial distribution of the different types of phosphate deposits worldwide (Pufahl & Groat, 2017).

Sedimentary phosphates are formed along continental margins and in epicontinental seas where the depth allows for a constant, periodic, or occasional reworking of the water-sediment interface (Baturin, 1982; Glenn et al., 1994; Föllmi, 1996; Pufahl & Groat, 2017).

The key element in the formation of these sedimentary phosphates is the action of the upwelling currents, which plays a role in supplying phosphorus, silica, and fluorine to the sedimentary environment that functions as a trap zone.

Phosphorite depositional environments. Large deposits form on passive continental margins with associated coastal upwelling (Pufahl 2017)

Fig 2. Different phosphorite depositional environments (Pufahl 2017).

II. The Moroccan Phosphate:

Moroccan phosphates are part of the South-Tethyan Phosphatogenic Province, a vast region that stretches approximately 5,500 kilometers from North Africa to the Middle East. Remarkably, this province holds a staggering 85% of the world's known phosphate reserves, as reported by Jasinski in 2020.

From a geological and stratigraphic standpoint, this province boasts an extensive age range, spanning from the Upper Cretaceous to the Paleogene, specifically from the Turonian to the Ypresian epochs, covering a time span of 46 million years.

Notably, Morocco stands as the epicenter of the global phosphate reserve landscape, with a commanding 72% share of the world's reserves and boasting the most substantial deposits on the planet.

Fig 3. Distribution of phosphate reserves worldwide (Jasinski, 2020).

The Moroccan phosphate deposits are primarily of sedimentary nature, ranging from the Maastrichtian epoch to the Ypresian epoch, and are found in the Meseta, Atlas, and Saharan regions.

The Meseta Region: Here, the most significant deposits are found, both in terms of their extent and their high P_2O_5 content.

- Ouled Abdoun Basin (Khouribga region).
- Ganntour Basin (Ben Guerir-north of Marrakech region).
- Meskala Basin (Imin T'anout – Chichaoua regions, East of Essaouira).

The Atlas Region: In this region, there are phosphate deposits with very low economic interest.

- Souss and Ouarzazate Basins: South slope of the Western to Central High Atlas.
- Aït Ourir to Amez Miz region: North slope of the High Western High Atlas (High Atlas of Marrakech).

- Bekrit and Timahdit regions (Maastrichtian): Deposits in the Middle Atlas.

Saharan Region: Here, phosphate deposits of moderate economic interest are found, with the only basin in this domain being the Oued Eddahab Basin.

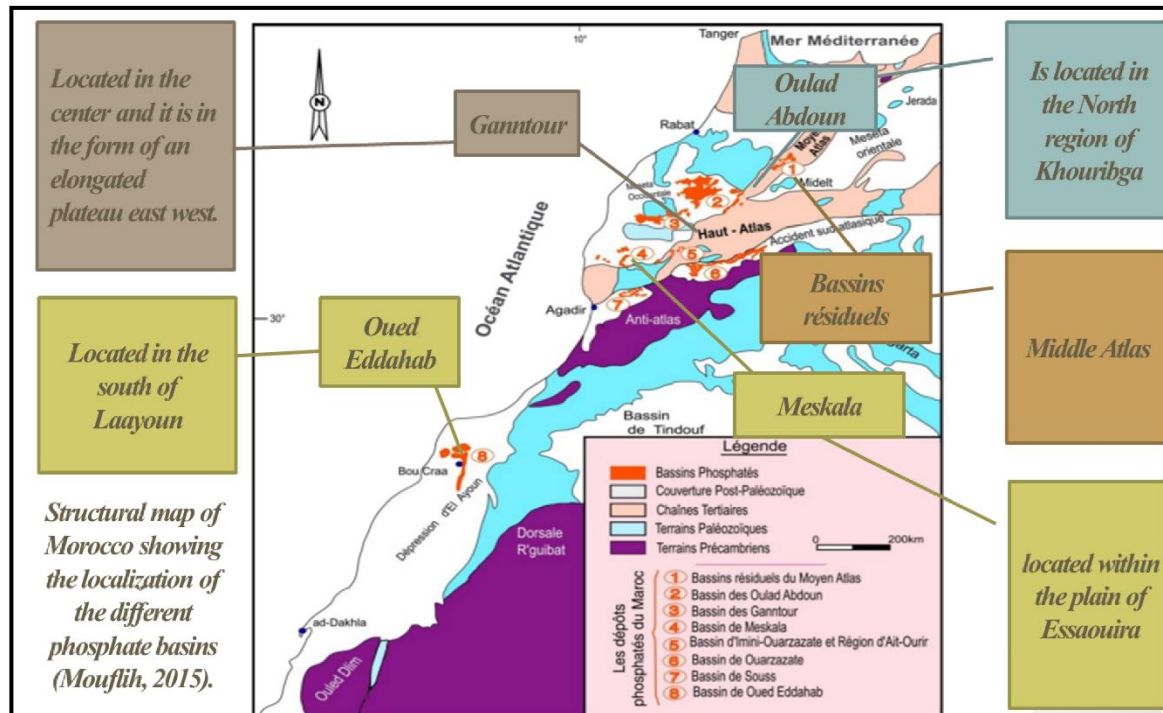

Fig 4. Structural map of Morocco showing the different phosphate basins (Mouflih, 2015).

These Moroccan phosphate deposits are characterized by a high phosphorus accumulation and low impurity levels.

These phosphates consist of phosphatic elements resembling fine wet sand and sterile elements (limestone, silica, clay-limestone gangue, etc.), with particle sizes ranging from a few millimeters to several tens of centimeters. They exhibit low concentrations of silica, iron, and alumina, but are generally quite carbonated.

III. The Paleogeography of the Maastrichtian of the western High Atlas:

The Geographical Context:

The Western High Atlas, more specifically, its southern side referred to as “the Souss-Ouarzazate Gulf” is a region distinguished by its geological division resulting from the uplift of the High Atlas Range, it is also characterized by the progressive transition from marine, through lagoonal, to continental facies along a west to east transect (Algouti et al., 2015).

The study area is located in the Western High Atlas, bounded to the north by the Western Meseta, to the south by the Anti-Atlas, to the east by the Central High Atlas, and to the west by the Agadir-Essaouira Basin. It encompasses the South Sub-Atlasic trough, which extends from Agadir and the Erguita trench in the west to the Aoulouz region in the east.

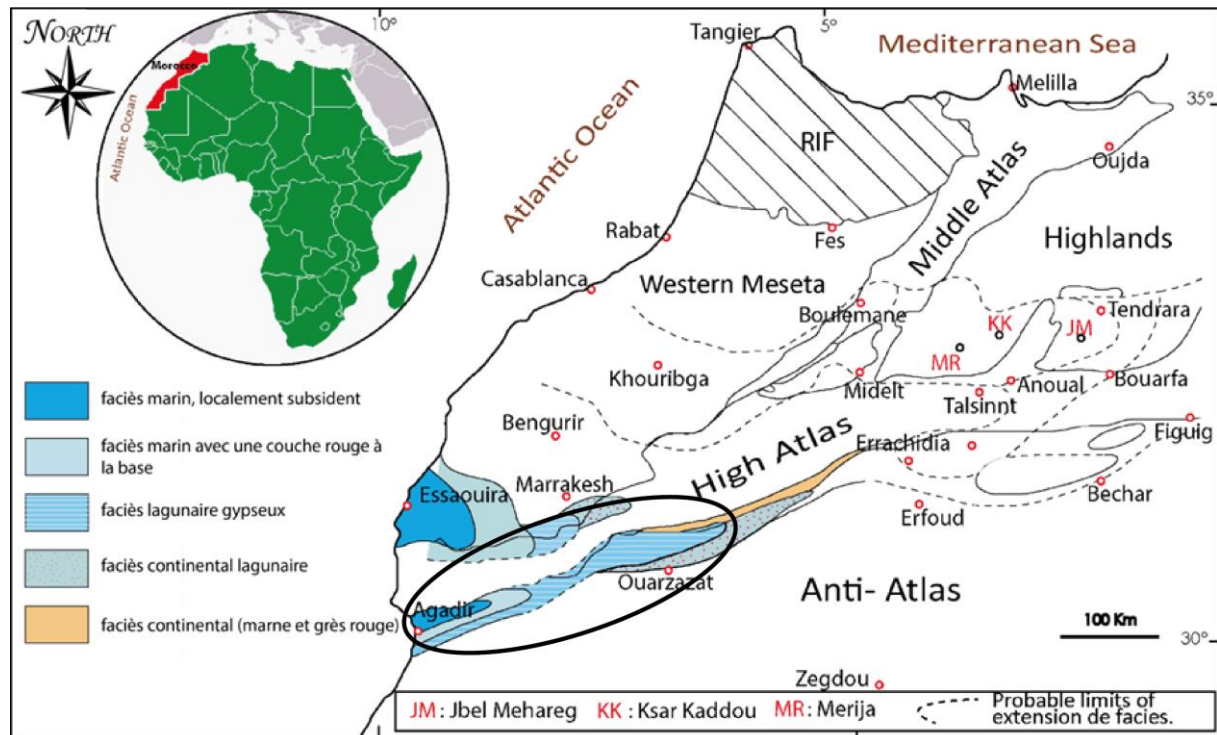

Fig 5. A location map illustrating the distinct facies within the study sectors. (Modified after Choubert and Faure-Muret 1960-62)

The Paleogeography:

During the Maastrichtian epoch, a substantial transgressive event originating from the Atlantic Ocean inundated the entire study region, encompassing the Moroccan coastline, the Saharan platform, southern Tunisia, and eastern Egypt. This transgression was driven by eustatic factors. However, it was preceded by a pre-Maastrichtian embryonic phase characterized by lithified strata at the roof of the Erguita region within the Oued Lahouar marl formation that is associated with an erosional surface overlain by micro-conglomerates. Notably, syndimentary faults and angular unconformities were identified at the base of the Maastrichtian, demarcating a significant geological shift. Furthermore, the transition coincided with the onset of phosphogenesis and the presence of colloidal silica seas.

The study area exhibits characteristics akin to small sedimentary basins, featuring lagoon-brackish influences in the eastern sector, which acted as morphological traps promoting the precipitation of phosphate minerals. The prevailing warm and arid climatic conditions facilitated the proliferation of vertebrate organisms, as evident in the Erguita Basin.

The absence of phosphogenesis in the Agadir Basin can be attributed to its geographical separation from the Erguita Basin by a shallower region. Researchers had previously identified this separation dating back to the Campanian period.

2.CONCLUSION

The surveyed sector manifests as follows:

The Agadir basin, which is in open communication with the sea, it is characterized by relatively deep fossiliferous sediments.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

The Erguita basin, it functions as a trap zone facilitating phosphate precipitation, within a hot and arid climate conducive to the proliferation of vertebrate organisms.

And the eastern portion behaves as small sedimentary basins exhibiting lagoon-brackish influences.

ABSTRACT

As everywhere, the reservoirs are water-wet and sometimes alternate with oil-wet areas. In the case of examining the only well in Albania where polymer injection is carried out, that of Patos Marinza, we see the same rule, where, as a result, with the use of wells, the saturation of the night in the reservoir decreases, and as a result, the amount of oil will be called extractable oil. As a result, the wet oil parts of the layer will be reduced, and the water-wetting of the rock will be observed. Regarding the injection of the polymer, it is observed that it is greatly affected by the wettability of the core. Wettability is defined as the tendency of a liquid to spread or adhere to the surface of a solid surface in the presence of another immiscible fluid. Reservoir wettability is an important and elusive petro-physical parameter in all types of core analysis, which affects saturation and improves oil recovery processes. In the engineering concept for the exploitation of the oil reservoir, there is the opinion that in water-wet cores, injection is done more efficiently than in oil-wet cores, that is, more in the first stages of injection from water-wet rocks than oil-wet ones. The polymer flooding process involves the injection of a polymer "plug," followed by continuous and long-term water flooding to drive the polymer plug and the oil "bank" ahead of it toward the production wells. Based on the principle of mobility ratio, as we showed above, water-soluble polymers reduce water mobility by two mechanisms: a) by increasing the viscosity of the aqueous phase; b) by reducing the relative permeability of water in the rock pores; and c) by adsorption and retention of the polymer at the mouths of the rock pores, thus creating a more efficient and uniform front to displace the contained oil from the reservoir. The mineralogy of the analyzed samples showed a variable amount of dolomite in their composition, which consists of dolomite grains and a small amount of dolomicrite in excellent form. The quality of the sand reservoir in Driza seems to be very good. The porous sand and pore system are practically immaculate. This can create a problem with narrow-pored throats. Injection of the polymer is also associated with the concern of its stability against several factors. The factors that affect the stability of the polymer, and therefore its effectiveness, are injection pressure, temperature, stirring speed, salinity of water, etc.

Keywords: Polymer Injection, Oil Reservoirs, Petro-Physical Parameters, Wettability.

Review of Related Literature on Mutual Wetting Capabilities of Oil-Water: Polymer: *Rock in Some Oil Fields in Albania.*

The mutual wetting capabilities of oil-water, polymer, and rock play a crucial role in the efficiency of oil recovery processes in oil fields. Understanding the interfacial interactions between these components is essential for optimizing oil production techniques. This literature review aims to explore the current knowledge and research findings on the mutual wetting capabilities of oil-water, polymer, and rock in some oil fields in Albania. The most important parameters influencing the direction of the better oil production using polymers, which have been distinguished from the other factors, are as follows:

Interfacial Tension and Wettability

Interfacial tension (IFT) and wettability are key parameters that influence the behaviour of fluids in porous media. The IFT between oil and water determines the capillary forces, which affect the displacement efficiency during oil recovery processes. The wettability of rock surfaces determines the preferential wetting phase and affects the distribution of fluids within the reservoir.

Polymer Flooding

Polymer flooding is an enhanced oil recovery technique that injects polymer solutions into the reservoir to improve oil displacement efficiency. The success of polymer flooding depends on the mutual wetting capabilities of oil-water, polymer, and rock. Understanding the interactions between these components is crucial for designing effective polymer flooding processes.

Mutual Wetting Capabilities in Albanian Oil Fields

Limited research has been conducted on the mutual wetting capabilities of oil-water, polymer, and rock in Albanian oil fields. However, some studies have shed light on this topic. For instance, a study by Xhafa et al. (2018) investigated the wettability alteration of carbonate reservoir rocks in the Patos-Marinza oil field. The research revealed that the addition of polymers to the injected water altered the wettability of the rocks, leading to improved oil recovery. Another study by Krasniqi et al. (2019) evaluated the effect of different polymers on the interfacial tension between oil and water in the Albanian oil fields. The results showed that certain polymer additives reduced the IFT, enhancing the oil recovery process. The study also highlighted the importance of polymer concentration and molecular weight in determining mutual wetting capabilities. Understanding the mutual wetting capabilities of oil, water, polymer, and rock in oil fields in Albania involves studying the interactions at the oil-water-rock interfaces and how they affect wettability and capillary forces. While there is limited information specifically about oil fields in Albania, here are some general points to consider:

Wettability Alteration: Wettability alteration refers to changing the wetting properties of the rock surface from oil-wet to water-wet. This alteration is crucial for enhanced oil recovery (EOR), as it improves the displacement of oil by water (Liu, et al., 2021). The favorable wettability alteration towards water-wet conditions has been identified as the primary mechanism for incremental oil recovery (Almorihil et al., 2021).

Polymer Flooding Techniques: Polymer flooding is an EOR method that involves injecting polymer solutions into the reservoir to improve sweep efficiency and the displacement of oil. Polymer flooding techniques can also affect rock wettability. However, specific details about

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

the effects of polymer flooding on rock wettability in Albanian oil fields are not readily available.

Pore-Scale Dynamics: The dynamics of water injection in oil-wet reservoir rocks play a significant role in understanding wetting capabilities. Studies have shown that water advances as a connected front, displacing oil in the center of the pores and confining the oil to wetting layers (Alhosani, 2020). The displacement process is an invasion percolation process, where throats between pores fill in order of size. It is important to note that the specific mutual wetting capabilities of oil-water, polymer, and rock in oil fields in Albania may vary depending on the geological characteristics of the reservoirs and the specific EOR techniques employed. Further research and studies specific to Albanian oil fields would provide more detailed insights into this topic.

The impact of rock wettability on oil recovery in Albania's oil fields is significant. The wettability of a rock affects the displacement of oil by water from the oil-producing reservoir rocks. Wettability plays an important role in oil recovery because of its effect on fluid location, flow behavior, and residual oil distribution (Wettability, 2012). The favorable wettability alteration towards water-wet conditions has been identified as the main mechanism responsible for incremental oil recovery. The influence of wettability on oil recovery is profound, and it depends on the reservoir mineralogy, the adsorption of hydrocarbon constituents, and the spreading capability of the oil phase. Therefore, understanding the mutual wetting capabilities of oil, water, polymer, and rock is crucial for enhanced oil recovery. Further research and studies specific to Albanian oil fields would provide more detailed insights into this topic (Agbalaka et al., 2008).

The degree of depletion of oil operated by the primary methods using energy reserves small, and in most cases does not exceed 5% to 30% of the geological resources. The exploitation of these deposits it is more effective when they are methods used to support the extraction (secondary and tertiary methods), allows for additional oil extraction by providing for additional deposits. The application of these methods allows a double to increase in the oil recovery. The best results are achieved when secondary and tertiary methods are matched to the parameters of oil and field conditions, including petrophysical properties such as relative permeability, saturation, and wettability.

The wettability type of reservoir rocks and their impact on the petrophysical properties are crucial in determining the oil recovery mechanisms and estimating the efficiency of their production. Numerous studies indicate that wettability is one of the main factors controlling and regulating the spread of oil and water in the reservoir rock (Url 1.; Url 2; Arekhov et al., 2020). The characterization of the wettability of reservoir rock plays an essential role in optimizing oil recovery. Nature's wettability (hydrophobic or hydrophilic) affects the behavior of reservoir rock, in particular for the waterflooding of the deposit and in the case of using advanced methods of oil recovery. For example, a wrong assumption of the hydrophilic nature of the rocks, where they are hydrophobic, can lead to permanent damage deposits and complicate the process of its operation [Arekhov et al., 2020; Sheng, 2011; Arekhov et al., 2020).

• **The mutual wetting capabilities of oil-water can affect oil recovery in Albanian oil fields in several ways:** Wettability determines the efficiency of gasflood oil recovery. According to a review article on the effect of wettability on oil recovery, it has been shown that wettability

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

determines the gasflood oil recovery efficiency, and changes in wetting states have resulted in observed improved recovery.

- **Rock wettability alteration towards more water-wetting conditions can improve oil recovery:** A study on water flooding in oil reservoirs found that rock wettability alteration towards more water-wetting conditions helps improve oil recovery. This is because the strong wetting preference of the rock for water and associated strong capillary-imbibition forces give the most efficient oil displacement.

- **Enhanced Oil Recovery (EOR) technologies can improve oil recovery:** According to a review of EOR status and opportunities to increase final recovery factors in reservoirs ranging from extra heavy oil to gas condensate, EOR technologies will play a key role in meeting the energy demand in years to come. EOR techniques such as waterflooding, thermal EOR, gas EOR, chemical EOR, and combined EOR can improve the mutual wetting capabilities of oil-water, polymer, and rock and increase oil recovery.

- **Heavy oil production requires EOR technologies:** According to a report on the characterization of crude oil from various oil fields in Albania, the majority of Albania's oil produced is heavy oil, meaning lower recovery rates and circumstances requiring EOR technologies.

Overall, the mutual wetting capabilities of oil-water can affect oil recovery in Albanian oil fields, and EOR technologies can be used to improve oil recovery rates.

Overall, the current EOR techniques used in Albanian oil fields to improve oil recovery through mutual wetting capabilities of oil-water include waterflooding, thermal EOR, gas EOR, chemical EOR, and combined EOR. These techniques are used to improve the mutual wetting capabilities of oil-water, polymer, and rock and increase oil recovery (Buranaj Hoxha et al., 2019).

Are there any case studies or success stories of EOR techniques that improve mutual wetting capabilities of oil-water in Albanian oil fields?

While there is no specific experimental setup or laboratory schematic facility for studying the improved mutual wetting capabilities of oil-water in Albanian oil fields, the experimental methods for studying the wetting properties of oil reservoirs and laboratory waterfloods can provide insights into the mutual wetting capabilities of oil-water, polymer, and rock in the region.

The research findings on the mutual wetting capabilities of oil-water, polymer, and rock in Albanian oil fields have several implications for oil extraction in the region. Some of these implications are:

- The study highlights the importance of understanding the wettability of different materials in oil recovery. This knowledge can help in the development of more effective oil extraction techniques in Albanian oil fields.
- The research findings suggest that the mutual wetting capabilities of oil, water, polymer, and rock can be influenced by various factors, such as surface tension and contact angle. Therefore, it is important to consider these factors when designing oil recovery processes (Url 3).

September 14-15, 2023, Naples, Italy

→ The study may have implications for the development of waste-to-fuel technology in Albanian oil fields. This technology could help to implement a renewable energy system in Europe's largest onshore oilfield.

The research findings could contribute to the broader understanding of wettability and wetting behaviour in other geological and industrial contexts. The study could also inform future research on the potential applications of the findings in developing new materials or technologies for oil recovery. The limitations of the research study on the mutual wetting capabilities of oil-water, polymer, and rock in Albanian oil fields are not explicitly stated in the search results. However, some limitations can be inferred based on the nature of the study and the available information. These limitations include:

The study focuses only on the mutual wetting capabilities of oil-water, polymer, and rock in Albanian oil fields. Therefore, the findings may not be generalizable to other oil fields or geological contexts (Kokinou et al. 2017).

The study may not have considered all the factors influencing the mutual wetting capabilities of oil-water, polymer, and rock. For example, the study may not have explored the effects of temperature, pressure, or the presence of other chemicals on wettability (Buranj Hoxha, 2022).

The study may have relied on laboratory experiments or simulations, which may not fully capture the complexity of real-world oil recovery processes in Albanian oil fields.

The study may not have considered the economic or environmental implications of the findings for oil extraction in Albanian oil fields.

The search results need to provide specific information on the oil fields in Albania that were studied in the research paper on the mutual wetting capabilities of oil-water, polymer, and rock. However, some of the search results provide information on oil production and extraction, which can help provide context for the study. So, it is difficult to determine how representative the findings are of the entire country. However, the information on oil production and extraction in Albania suggests that the study may have focused on oil fields in the Durres Basin and the Ionian unit, major oil production areas in the country. Nonetheless, further information is needed to determine the specific oil fields studied and their representativeness.

2. CONCLUSION

In conclusion, the mutual wetting capabilities of oil-water, polymer, and rock in Albanian oil fields have been investigated to a limited extent. However, the available studies suggest that polymers can alter the wettability of rocks and reduce the interfacial tension between oil and water, leading to improved oil recovery. Further research is needed to explore the specific mechanisms and optimize the use of polymers in oil production processes in Albania.

Conclusions for the research paper titled "The Mutual Wetting Capabilities of Oil-water, Polymer, and Rock in Albanian Oil Fields" could include:

The study found that oil-water, polymer, and rock wettability in Albanian oil fields is an essential factor in oil recovery; the research showed that various factors, such as surface tension and contact angle, can influence the mutual wetting capabilities of these materials; the study may have implications for developing more effective oil recovery techniques in Albanian oil fields.

TeMALab

September 14-15, 2023, Naples, Italy

The findings of this research could also contribute to the broader understanding of wettability and wetting behaviour in other geological and industrial contexts. Further research could explore the potential applications of the study's findings in developing new materials or technologies for oil recovery.

Based on the research study on the mutual wetting capabilities of oil-water, polymer, and rock in Albanian oil fields, the following recommendations for oil extraction can be made:

- The study highlights the importance of understanding the wettability of different materials in oil recovery. Therefore, it is recommended that oil extraction companies in Albanian oil fields consider the mutual wetting capabilities of oil-water, polymer, and rock when designing oil recovery processes;
- The research findings suggest that the mutual wetting capabilities of oil, water, polymer, and rock can be influenced by various factors, such as surface tension and contact angle. Therefore, it is recommended that oil extraction companies in Albanian oil fields take these factors into account when designing oil recovery processes.
- The study may have implications for the development of waste-to-fuel technology in Albanian oil fields. Therefore, it is recommended that oil extraction companies in Albanian oil fields explore the potential of this technology to implement a renewable energy system in the region.
- The research findings could contribute to the broader understanding of wettability and wetting behaviour in other geological and industrial contexts. Therefore, it is recommended that oil extraction companies in other regions consider the study's findings when designing oil recovery processes. Further research could explore the potential applications of the study's findings in the development of new materials or technologies for oil recovery. Therefore, it is recommended that oil extraction companies in Albanian oil fields invest in research to develop more effective and sustainable oil recovery techniques.

Based on the search results, potential future research directions in the field of mutual wetting capabilities of oil-water, polymer, and rock in some oil fields in Albania could include:

- ♣ Further exploration of the factors that influence the mutual wetting capabilities of oil-water, polymer, and rock in Albanian oil fields. This could include investigating the effects of temperature, pressure, and the presence of other chemicals on wettability.
- ♣ Development of new materials or technologies for oil recovery based on the study's findings. For example, the study could inspire the development of new surfactants or polymers that can improve the mutual wetting capabilities of oil-water, polymer, and rock in Albanian oil fields.
- ♣ Investigation of the economic and environmental implications of the study's findings for oil extraction in Albanian oil fields. This could include assessing the cost-effectiveness and sustainability of different oil recovery techniques based on their mutual wetting capabilities.
- ♣ Further characterization of crude oil from various oil fields in Albania through instrumental analysis techniques such as gas chromatography-mass spectrometry (GC-MS), Fourier transform infrared spectroscopy (FTIR), and nuclear magnetic resonance (NMR) spectroscopy. This could help to understand better the chemical and physical properties of crude oil in Albanian oil fields and their potential implications for oil recovery.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

The following are some ways in which the findings can be used to improve oil recovery in Albanian oil fields:

a. Consideration of mutual wetting capabilities in oil recovery processes: The study highlights the importance of understanding the mutual wetting capabilities of oil-water, polymer, and rock in Albanian oil fields. Therefore, oil extraction companies in Albanian oil fields can consider the mutual wetting capabilities of these materials when designing oil recovery processes. This can help to develop more effective and sustainable oil recovery techniques.

b. development of new materials or technologies for oil recovery: The research findings suggest that various factors, such as surface tension and contact angle, can influence the mutual wetting capabilities of oil-water, polymer, and rock. Therefore, the study could inspire the development of new surfactants or polymers to improve the mutual wetting capabilities of oil-water, polymer, and rock in Albanian oil fields. This could lead to more effective and sustainable oil recovery techniques.

c. Investigation of waste-to-fuel technology: The study may have implications for developing waste-to-fuel technology in Albanian oil fields. This technology could help to implement a renewable energy system in Europe's largest onshore oilfield.

d. characterization of crude oil through instrumental analysis: The characterization of crude oil from various oil fields in Albania through instrumental analysis techniques such as gas chromatography-mass spectrometry (GC-MS), Fourier transform infrared spectroscopy (FTIR), and nuclear magnetic resonance (NMR) spectroscopy, can help to understand better the chemical and physical properties of crude oil in Albanian oil fields. This can inform the development of more effective and sustainable oil recovery techniques.

e. Investigation of Enhanced Oil Recovery (EOR) technologies: With the decline in oil discoveries during the last decades, it is believed that Enhanced Oil Recovery (EOR) technologies will play a key role in meeting the energy demand in future years. Therefore, oil extraction companies in Albanian oil fields can investigate EOR technologies to increase final recovery factors in reservoirs ranging from extra heavy oil to gas condensate.

Final Considerations for Mutual Wetting Capabilities of Oil-Water: Polymer: Rock in Some Oil Fields in Albania:

- ✓ Many studies highlight the importance of understanding the mutual wetting capabilities of oil-water, polymer, and rock in Albanian oil fields to improve recovery.
- ✓ The research findings suggest that various factors, such as surface tension and contact angle, can influence the mutual wetting capabilities of oil-water, polymer, and rock. Therefore, it is essential to consider these factors when designing oil recovery processes.
- ✓ The study may have implications for developing waste-to-fuel technology in Albanian oil fields. This technology could help to implement a renewable energy system in Europe's largest onshore oilfield.
- ✓ The research findings could contribute to the broader understanding of wettability and wetting behaviour in other geological and industrial contexts.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

- ✓ The current oil recovery methods used in Albanian oil fields include primary oil extraction techniques, EOR techniques, transfer of heavy-oil technology, and onshore and offshore oil and gas opportunities.
- ✓ The EOR techniques used in Albanian oil fields include waterflooding, thermal EOR, gas EOR, chemical EOR, and combined EOR.

Potential future research directions in the field of mutual wetting capabilities of oil-water, polymer, and rock in some oil fields in Albania could include: further exploration of the factors that influence mutual wetting capabilities, development of new materials or technologies for oil recovery, Investigation of the economic and environmental implications of the study's findings, further characterization of crude oil through instrumental analysis, and Investigation of Enhanced Oil Recovery (EOR) technologies.

A SURVEY OF MACHINE LEARNING-BASED PREDICTION METHODS FOR HEART DISEASE

Mrs. A. Rajeswari (ORCID: 0009-0005-7906-5089)

G. Venkataswamy Naidu College, Kovilpatti, Tamilnadu, India

Email: rajeswari@gvncollege.edu.in

ABSTRACT

The heart is one of the body's most vital organs. All of the body's organs benefit from improved blood circulation and filtration. Heart diseases are to blame for the majority of deaths worldwide. There are other symptoms that are noted, including as chest pain, a rapid heartbeat and difficulty breathing. This information is regularly analyzed. This review starts off with a general introduction of heart disease and the current treatments. Additionally, a thorough examination of the most pertinent machine learning methods for heart disease prediction that have been documented in the literature is briefly elaborated. Decision tree, SVM, ANN, Naïve Bayes, Random Forest, and KNN are some of the machine learning algorithm that have been discussed, The algorithms are contrasted based on their properties. On the most accurate algorithm, we are now working. This will make it easier for the doctors to treat the cardiac issue.

Keywords: Machine Learning, Prediction, Classification Technique, Decision Tree, Accuracy.

1. INTRODUCTION

Heart disease affects the functioning of the heart. World Health Organization had made a survey and made a conclusion that 10 million people are affected with heart disease and lost their lives. The problem that the Healthcare industry faces in today's life is early prediction of disease after a person is affected. Records or data of medical history is very large and the data in the real world might be incomplete and inconsistent. In the past predicting the disease effectively and treatment to patients might not be possible for every patient at early stages under these circumstances. Many scientists tried to build a model which is capable of predicting the heart disease in the early stage, but they are not able to build a perfect model. Every proposed system has disadvantages in its own way. In the existing system, Shen et al. had initially proposed a system which is based on self-applied questionnaire. In this system the user needs to enter all the symptoms which he is suffering from, based on that the result is predicted. This study is based on the analysis data collected in SAQ. Chen et al. came up with an idea to predict heart disease. He used the technique of Vector Quantization which is one of the artificial intelligence techniques for classification and prediction purposes. Training of neural networks is performed using back propagation to evaluate the prediction system. In the testing phase approximately 80% accuracy is achieved on the testing set. Practical use of data collected from previous records is time consuming. Low accuracy rate. So to overcome this we are implementing Random forest algorithm in order to achieve accurate results in less time. Machine learning is given a major priority in modern life in many applications and in the healthcare sector. Prediction is one of the areas where machine learning plays a vital role. Our topic is to predict heart disease by processing patient's dataset and a data of patients i.e., user of whom we need to predict the chances of occurrence of a heart disease.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Heart disease can be detected using symptoms like: high blood pressure, chest pain, hypertension, cardiac arrest, etc. There are many types of heart diseases with different types of symptoms. Like: 1) heart disease in blood vessels: chest pain, shortness of breath, pain in neck Throat. 2) Heart disease caused by abnormal heartbeats: slow heartbeat, discomfort, chest pain. etc. Most common symptoms are chest pain, shortness of breath, discomfort, chest pain. etc. Most common symptoms are chest pain, shortness of breath, fainting. Causes of heart disease are defects you're born with, high blood pressure, diabetes, smoking, drugs, and alcohol. Sometimes in heart disease the infection also affects the inner membrane, which is identified by symptoms like fever, fatigue, dry cough, skin rashes. Causes of heart infection are bacteria, viruses, parasites. Types of heart disease: Cardiac arrest, Hypertension, Coronary artery disease, Heart failure, Heart infection, congenital heart disease, slow heartbeat, Stroke type heart disease, angina pectoris. Nowadays there are too many automated techniques to detect heart disease like data mining, machine learning, deep learning, etc. So, in this paper we will briefly introduce machine learning techniques. In this we train the datasets using the machine learning repositories. There are some risk factors on the basis of that the heart disease is predicted. Risk factors are: Age, Sex, Blood pressure, Cholesterol level, Family history of coronary illness, Diabetes, Smoking, Alcohol, Being overweight, Heart rate, Chest Pain.

A. Problem Statement

Heart disease can be managed effectively with a combination of lifestyle changes, medicine and, in some cases, surgery. With the right treatment, the symptoms of heart disease can be reduced and the functioning of the heart improved. The predicted results can be used to prevent and thus reduce cost for surgical treatment and other expensive.

B. Objectives

The main objective of this research is to develop a heart prediction system. The system can discover and extract hidden knowledge associated with diseases from a historical heart data set. Heart disease prediction system aims to exploit data mining techniques on medical data set to assist in the prediction of the heart diseases.

C. Methodology

Figure 1 depicts the overall process of this work. Our aim is to build an application of heart disease prediction system using robust Machine Learning algorithm which is Random Forest algorithm. A CSV file is given as input. After the successful completion of operation the result is predicted and displayed. The working of the system starts with the collection of data and selecting the important attributes. Then the required data is pre- processed into the required format. The data is then divided into two parts training and testing data. The algorithms are applied and the model is trained using the training data. The accuracy of the system is obtained by testing the system using the testing data. This system is implemented using the following modules.

- 1) Collection of Dataset
- 2) Selection of attributes
- 3) Data Pre-Processing
- 4) Balancing of Data

5) Disease Prediction

Fig. 1 Block diagram of proposed system

2. LITERATURE SURVEY

This section discusses the state-of-the-art methods for heart disease diagnosis using machine learning techniques that were accomplished by various effective research works. R. Perumal et al. [18] developed a heart disease prediction model using the Cleveland dataset of 303 data instances through feature standardization and feature reduction using PCA, where they identified and utilized seven principal components to train the ML classifiers. They concluded that LR and SVM provided almost similar accuracy values (87% and 85%, respectively) compared to that of k-NN with 69%. Latha et al. [19] performed a comparative analysis to improve the predictive accuracy of heart disease risk using ensemble techniques on the Cleveland dataset of 303 observations. They applied the brute force method to obtain all possible attribute set combinations and trained the classifiers. They achieved a maximum increase in the accuracy of a weak classifier of 7.26% based on ensemble algorithm, and produced an accuracy of 85.48% using majority vote with NB, BN, RF, and MLP classifiers using an attribute set of nine attributes. Ananey-Obiri et al. [20] developed three classification models, namely, LR, DT, and Gaussian naïve Bayes (GNB), for heart disease prediction based on the Cleveland dataset. Feature reduction was performed using single value decomposition, which reduced the features from 13 to 4. They concluded that both LR and GNB had predictive scores of 82.75% and AUC of 0.87. It was suggested that other models, such as SVM, k-NN, and random forest, be included. Kumar et al. [21] trained five machine learning classifiers, namely, LR, SVM, DT, RF, and KNN, using a UCI dataset with 303 records and 10 attributes to predict cardiovascular disease. The RF classifier achieved the highest accuracy of 85.71% with an ROC AUC of 0.8675 compared to the other classifiers. Gupta et al. [22] replaced the missing values based on the majority label and derived 28 features using the Pearson correlation coefficient from the Cleveland dataset and trained LR, KNN, SVM, DT, and RF classifiers using the factor analysis of mixed data (FAMD) method; the results based on a weight matrix RF

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

achieved the best accuracy of 93.44%. Sultana et al. [23] explored KStar, J48, sequential minimal optimization (SMO), BN, and MLP classifiers using Weka on a standard heart disease dataset from the UCA repository with 270 records and 13 attributes; they achieved the highest accuracy of 84.07% with SMO. Mohan et al. [24] developed an effective hybrid random forest with a linear model (HRFLM) to enhance the accuracy of heart disease prediction using the Cleveland dataset with 297 records and 13 features. They concluded that the RF and LM methods provided the best error rates. Kodati et al. [25] developed a heart disease prediction system (HDPS) with the Cleveland dataset of 297 instances and 13 attributes using Orange and Weka data mining tools, where they evaluated the precision and recall metrics for the naïve Bayes, SMO, RF, and KNN classifiers. Ed-daoudy et al. [26] researched the Cleveland dataset of 303 records and 14 attributes from UCI. They evaluated the performance of the four main classifiers, namely, SVM, DT, RF, and LR, using Apache Spark with its machine learning library MLib. Tougui et al. [27] compared the performances of LR, SVM, KNN, ANN, NB, and RF models to classify heart disease with the Cleveland dataset with 297 observations and 13 features using six data mining tools: Orange, Weka, RapidMiner, Knime, MATLAB, and Scikit-Learn. Pavithra et al. [28] proposed a new hybrid feature selection technique with the combination of random forest, AdaBoost, and linear correlation (HRFLC) using the UCI dataset of 280 instances to predict heart disease. Eleven (11) features were selected using filter, wrapper, and embedded methods; an improvement of 2% was found for the accuracy of the hybrid model. Gazeloglu et al. [29] projected 18 machine learning models and 3 feature selection techniques (correlation-based FS, chi-square, and fuzzy rough set) to find the best prediction combination for heart disease diagnosis using the Cleveland dataset of 303 instances and 13 variables. Louridi et al. [30] proposed a solution to identify the presence/absence of heart disease by replacing missing values with the mean values during pre-processing. They trained three machine learning algorithms, namely, NB, SVM (linear and radial basis function), and KNN, by splitting the Cleveland dataset of 303 instances and 13 attributes into 50:50, 70:30, 75:25, and 80:20 training and testing ratios. Kavitha et al. [31] implemented a novel hybrid model on the Cleveland heart dataset of 303 instances and 14 features with a 70:30 ratio for training and testing by applying DT, RF, and hybrid (DT + RF) algorithms. Tama et al. [32] designed a stacked architecture to predict heart disease using RF, gradient boosting machine, and extreme gradient boosting with particle swarm optimization (PSO) feature selection using various heart disease datasets, including the Cleveland with 303 instances and 13 attributes.

From the experimental works, it is understood that data pre-processing and feature selection can substantially enhance the classification accuracy of machine learning algorithms. During pre-processing, most researchers [18,19,21,22,26,29–32] replaced the missing values, either by using the mean value or the majority mark of that attribute, to make sure the dataset was comprehensive. In some works [20,24,25,27], the missing valued instances were removed. Feature selection is a challenging task due to the large exploration space. It grows exponentially according to the number of features available in the dataset. To solve this issue, an effective comprehensive search technique is required during feature selection. Furthermore, some studies have employed ensemble models, which combine multiple basic learning algorithms to obtain a better prediction accuracy. However, the performance of these techniques can further be improved regarding accurately predicting disease.

3. SYSTEM DESIGN

System design is thought of as the application of the theory of the systems for the development of the project. System design defines the architecture, data flow, use case, class, sequence and activity diagrams of the project development.

A. System Architecture

The below architecture diagram in Figure 2 illustrates how the system is built and is the basic construction of the software method. Creation of such structures and documentation of these structures is the main responsibility of software architecture.

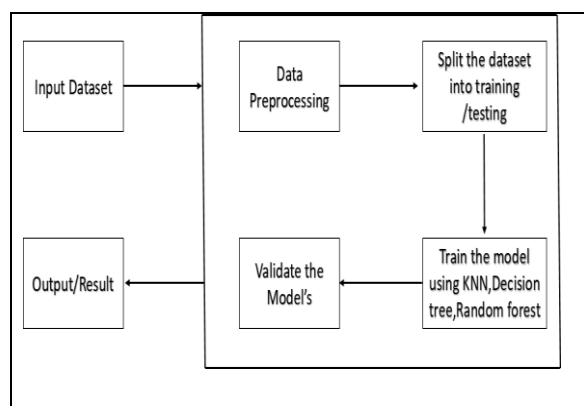

Fig. 2 Architecture diagram of proposed system

The working principle of the system is shown in Fig. 2.

1) **Input Dataset:** The user enters the input.

2) **Data Pre-Processing:**

It can refer to manipulation or dropping of data before it is used in order to ensure or enhance performance and is an important step in the data mining process. Data pre-processing is an important step for the creation of a machine learning model. Initially, data may not be clean or in the required format for the model which can cause misleading outcomes. In pre-processing of data, we transform data into our required format. It is used to deal with noises, duplicates, and missing values of the dataset. Data pre-processing has activities like importing datasets, splitting datasets, attribute scaling, etc. Pre-processing of data is required for improving the accuracy of the model.

3) **Split Dataset Into Train and Test:**

The train-test split is used to estimate the performance of machine learning algorithms that are applicable to prediction-based Algorithms/Applications. This method is a fast and easy procedure to perform such that we can compare our machine learning model results to machine results.

4) **Train the Model:** Input which is compared with the data present in the existing data set by using the Random Forest Algorithm. It is an efficient ML algorithm that comes under supervised learning technique. It is used for both Regression and Classification problems. To solve a complex problem, it uses a process of combining multiple classifiers, to increase the accuracy

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

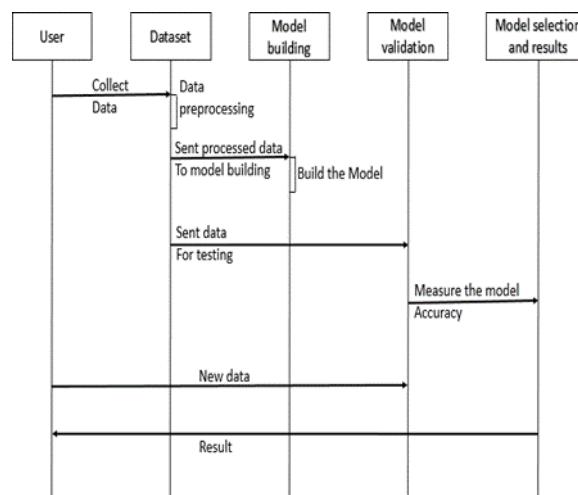

and performance of the model. "Random Forest is known as classifier that contains a greater number of decision trees on different subsets of the given dataset and considers the average to improve the predictive accuracy of that dataset."

5) Validate: Model validation refers to the process of confirming that the model actually achieves its intended purpose. In most situations, this will involve confirmation that the model is predictive under the conditions of its intended use.

6) Output or Result: Dataset collection is collecting data which contains patient details. Attributes selection process selects the useful attributes for the prediction of heart disease. After identifying the available data resources, they are further selected, cleaned, and made into the desired form. Different classification techniques as stated will be applied on pre-processed data to predict the accuracy of heart disease. Accuracy measure compares the accuracy of different classifiers.

B. Flowchart

The first step is to collect data on patients, which typically includes demographic information as well as medical history. The data is then cleaned and pre-processed to prepare it for analysis. The dataset is then split into training and testing sets. The training set is used to train the machine learning model, and the testing set is used to evaluate its performance. Various supervised learning algorithms can be used to train the model, such as logistic regression, decision trees, or neural networks. The accuracy of the model is then evaluated using the testing set. The model can be further optimized by adjusting the hyper parameters using techniques such as cross-validation and grid search. Once the model is optimized, it can be deployed in a real-world setting to predict the likelihood of heart disease in new patients.

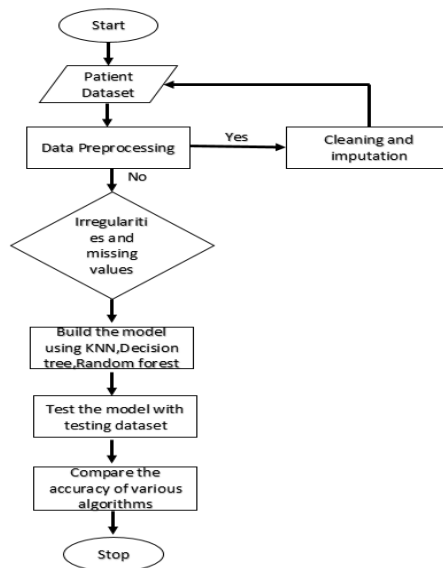

Fig. 3 Flowchart for heart prediction system

C. Sequence Diagram

A sequence diagram is a type of UML (Unified Modeling Language) diagram that depicts the interactions between objects or components in a system or process. It shows the order in which messages are exchanged between the objects, along with the time sequence of those messages. Below figure 4 shows the sequence diagram of crop and fertilizer recommendation.

5. CONCLUSION

Heart disease prediction is a major challenge in present modern life. With this application if the patient/user is away from reach of doctor, he/she can make use of the application in prediction of disease just by entering the report values. And can proceed further whether to consult a doctor or not.

6. FUTURE SCOPE

In future this application can be extended by updating some features like, if the user is affected with heart disease all his family members will be notified with a message in early. And also, the information should be passed to the nearest hospital. Another feature is there should be online doctor consultation with the nearest doctor available. In this regard, it is important to note that, ML applications using various efficient algorithms are utilized not only in disease prediction and diagnosis but also in the field of radiology, bioinformatics and medical imaging diagnosis etc.

ABSTRACT

Millions of lives have been destroyed by the deadly coronavirus, which has also put a tremendous amount of burden on the entire healthcare system. Early identification of COVID-19 is essential to isolating positive cases and halting the spread of the illness. For COVID-19 detection, combining deep learning algorithms with medical imagery led to faster and more accurate results. This paper comprehensively analyzes the most recent deep-learning techniques for COVID-19 diagnosis. According to research publications, convolutional Neural Networks (CNN) is the most popular deep learning techniques for COVID-19 identification from medical images. Pre-processing medical images is essential, transfer learning and data augmentation approaches can help with data scarcity issues, using pre-trained models can save time, and medical photos play a crucial part in the automatic detection of COVID-19. This article also gives young researchers a sane perspective on creating CNN models combined with medical imagery to detect diseases early.

Keywords: COVID-19 Detection, Image Processing, Deep Learning, CNN, X-ray Images, CT Images.

1. INTRODUCTION

The sickness known as the SARS-CoV-2 coronavirus brings on COVID-19. The World Health Organization (WHO) designated COVID-19 on February 11, 2020 (World Health Organization, 2020).¹ According to statistics from the World Health Organization as of June 2021, the sickness has spread to almost every country since the discovery of the first case and has already claimed the lives of over 4 million individuals among the roughly 180 million confirmed cases. Patients are screened in hospitals or primary care clinics as the initial step in the therapy of COVID-19.

Although transcription-polymerase chain reaction (PCR) testing is still mainly used for the ultimate diagnosis, medical imaging is currently the standard hospital protocol for patients with severe respiratory symptoms since it is quick and easy. However, at the moment, clinicians may encounter people in hospitals with pneumonia brought on simultaneously by the flu, other viruses, and COVID-19. Therefore, a rapid and precise detection method that can distinguish between the two types of pneumonia is required.

The diagnosis of COVID-19 frequently uses X-ray imaging methods because of their widespread availability, quick turnaround, and inexpensive cost. However, CT imaging methods are favored since they provide extensive information on the affected area. However, due to a lack of in-depth understanding of the illness, even for expert radiologists, identifying the infection from medical imaging has become complex. For the diagnosis of COVID-19, deep learning algorithms combined with medical imaging have proven to be a helpful option that produces quicker and more accurate findings. The primary purpose of the Convolutional Neural

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Network (CNN), a deep neural network used to detect COVID-19 from medical pictures, is pattern recognition.

This article aims to gather the methodology of recent studies on the automatic detection of COVID-19 from medical photos using deep learning algorithms. This essay compares the outstanding qualities of current deep learning techniques employing CT and X-ray imaging modalities. Models performed better when the datasets were enhanced, according to a study of models with and without data augmentation. Additionally, it gives young researchers a logical direction for creating CNN models that are incredibly effective when used with medical imagery to identify diseases early on. Several groups 14–16 have recently described COVID-19 pneumonia detection methods based on deep learning. Alshazly¹⁴ detected COVID-19 with accuracy, precision, and sensitivity of 93.96%, 99.13%, and 94%, respectively, using deep CNN architectures on CT-scan images. With a limited dataset of 339 appearances for training and testing, Ayrton¹⁵ presented a deep transfer learning technique based on ResNet50 and obtained a validation accuracy of 96.2%. Wang¹⁶ suggested five pre-trained deep learning models, and the Xception model had an effect close to ideal and an accuracy of 96.75%.

2 Deep Learning and Medical Image Analysis: Challenges And Opportunities

This section first summarizes existing deep learning and medical image processing methods for COVID-19 imaging. Then, we discuss challenges and possible prospects for this field's future research.

The generalizability of trained models from data, encompassing both the over fitting problem and the out-of-distribution problem, is a broad, enduring challenge in machine learning and deep learning. In other words, if a deep understanding or machine learning model performs well on training data, such as medical photos, but poorly on test data, the learned model likely employs over fitting features. Additionally, the so-called out-of-distribution problem will arise if the known models are evaluated on data sets that are systematically dissimilar from the training and test data. The generalizability problem is complicated and prevalent in radiology and medical imaging. The generalizability difficulty has been addressed using various strategies, including transfer learning, domain adaptation, training, radiography, and imaging in healthcare.

Similarly, the generalizability problem has long been a problem in medical image analysis because different imaging facilities or hospitals could produce medical image data sets with other cofactors and characteristics for the same type of disease or condition. The difficulty of this problem has increased for COVID-19 imaging and diagnosis, and numerous studies have been suggested to solve it. For better COVID-19 diagnosis utilizing CT images, Liu & Ji proposed a multi-stage attentive transfer learning architecture. Their approach specifically comprises three stages to build precise diagnosis models by learning from several source tasks and data from various areas. They created a novel self-supervised learning technique to teach lung CT pictures multiscale representations.

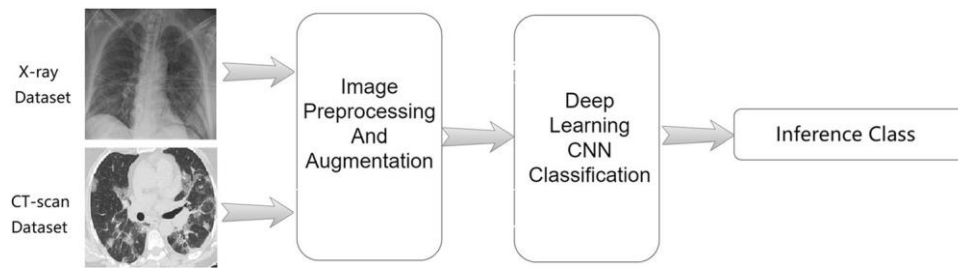

Fig 1. Deep Learning Based Screening Structure Of COVID-19.

Medical image analysis, notably the analysis of COVID-19 imaging data, has extensively used deep learning. It is also evident that deep learning is not being used in clinical radiology practices as quickly as was anticipated. One of the key causes is that radiologists and clinical physicians need more faith in and confidence in deep learning. Trust in a decision provided by deep learning, according to Xie et al., is based on a rationale that:

1. Simply understandable.
2. Relatable to the user.
3. Connects the decision with context regarding the choice or the user's prior experiences.
4. Reflects the user's intermediate thought process.

Despite its widespread appeal and effectiveness in solving many machine learning challenges, deep learning has many limits. First, deep learning models automatically learn representations from data, making them heavily reliant on data-driven learning paradigms. As a result, data-driven deep learning invariably results in known models that replicate or even amplify biases present in the data; this result has recently drawn much interest from the community. Many people have questioned the fairness of deep learning models in various application contexts, including medical imaging and COVID-19 imaging. These biases include prediction outcome discrimination and disparity in prediction quality. Second, as Poggio et al. noted, deep learning is still poorly understood theoretically, and many of its operations are regarded as black boxes.

The most frequently used modalities in the clinical imaging-based diagnosis of COVID-19 are radiography and CT. The Fleischner Society advises radiography and computed tomography (CT) in various situations; for instance, chest radiography is recommended for COVID-19 patients in a resource-constrained setting with limited access to CT. In addition, the preferred imaging modalities for COVID-19 diagnosis vary geographically. For instance, in China, early hospital admission for diagnosis of COVID-19 patients was urged as a public health policy, and COVID-19 infection is more likely to be detected with CT than early chest radiography.

3 Pre-Processing

Medical imaging is taking pictures of a person's inside organs to diagnose various physical problems. X-ray and CT are the two most often used medical imaging modalities for identifying COVID-19. However, because of the images' low intensity and contrast, the boundaries and margins are not visible, which could result in a mistaken disease diagnosis. Therefore, to improve the model's accuracy, it is imperative to pre-process medical images to extract the pertinent information and discard the rest. Medical image processing involves applying an algorithm to a digital image to improve the image quality of the raw medical data for further analysis.

4 Segmentation

Image segmentation is an important image processing method to improve the accuracy and dependability of the model's predictions. The lung region serves as the Region of Interest (ROI) for COVID-19 detection during segmentation. Separating the lung region from other background information in the medical pictures minimizes computational complexity.

a) Lung Images

b) Segmented Lung Images

Fig 2. Image segmentation samples

4. Image enhancement

Image enhancement is crucial for improving medical images' visual perception quality for diagnosis of illness. Histogram equalization is an improvement method that evenly distributes the intensity level throughout the image's pixels. In some instances, the strong contrast in the white region causes the information carried by the white pixels to be washed out. The intensity values are only distributed across a limited image portion through adaptive histogram equalization (AHE). It can cause the noise in the homogenous zones to be overamped. Contrast Limited Adaptive Histogram Equalization, or CLAHE, reduces the over-emphasis of noise brought on by AHE. Setting a maximum contrast limit at which the contrast cannot be improved improves the image by preventing noise from being amplified excessively.

September 14-15, 2023, Naples, Italy

a) Lung Images b) Enhanced Lung Images

Fig 3. Image enhancement samples

5. Dataset

Deep learning requires a large amount of data for the model to be trained efficiently and accurately. The data available in the dataset are split into three sets:

- i) Training dataset
- ii) Validation dataset
- iii) Test dataset.

The training dataset is used during the learning process to train the model to perform tasks. The validation dataset is used to evaluate, fine-tune model hyper parameters during the training process and facilitates in optimizing model selection. The test dataset is used to assess the model once it is completely trained using the training and the validation dataset. As COVID-19 is an ongoing and new pandemic, the available datasets are insufficient and imbalanced to train the model effectively.

6. Training, Validation, and Testing Split

The training dataset was divided into two parts: 20% was used to validate the already-built model, and the remaining 80% was used to make the model. The test dataset was used to assess the created model's actual performance after training without exposing it to it. 80% of the training data was split into five subsets for fivefold cross-validation. Chest X-ray scan images were used in either the test or train sets, but not both, without lossy compression.

The dataset was divided into 80% training and 20% testing to validate the developed model. The test dataset was not provided to the model during training and was used to verify the generated model's actual performance with metrics. To do five-fold cross-validation, 80 percent of the training data were further separated into five subgroups, and one subgroup was used to validate the training model.

7. Role of Datasets in the Detection of Covid - 19

Two popular medical imaging modalities that are used to identify and assess the severity of an infection are X-ray and CT. Each type of medical imaging has benefits and drawbacks. Due to its wide availability, X-ray imaging is the most often used medical imaging method for diagnosing COVID-19. It can be processed using straightforward steps, which reduce the amount of time spent imaging and lessens the risk of the virus spreading. When compared to other medical imaging modalities, it is affordable. Compared to a CT scan, it is non-invasive and generates minimal radiation exposure. Despite its advantages, X-rays are less sensitive, which may lead to a false prediction of the disease with early and mild symptoms.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

a) Normal Cases

b) COVID-19 Positive Cases

On the other hand, CT scans offer reliable results since they are susceptible, include comprehensive information about the affected area, and are sensitive. The diagnosis of lung anomalies mostly depends on CT imaging. Since it is more trustworthy, it aids in the early detection of COVID-19. However, CT screening has limited use due to expensive costs, increased radiation doses, and resource limitations.

Sl.No	Article/Year	Advantages	Limitations	Computational Complexity
1	Matias Cam Arellano & Oscar E Ramos / 2020	<ul style="list-style-type: none"> The model provided distinctive features as it is already trained for the detection of various lung diseases. The class imbalance problem is dealt with using the weighted loss function. 	<ul style="list-style-type: none"> The model was trained with less amount of dataset. Class imbalance of dataset needs to be focussed. 	<ul style="list-style-type: none"> Computationally less expensive as only two layers were added on top of the pre-trained DenseNet 121.
2	Abhijit Bhattacharya et al / 2021	<ul style="list-style-type: none"> Only focussed on the lung region in the X-ray images to provide explicit categorization of images. Histogram equalization was used to enhance the low contrast X-ray images for prominent training of the CNN model. 	<ul style="list-style-type: none"> The number of images used to train the model is low. 	<ul style="list-style-type: none"> Out of the pre-trained used, DenseNet-201 took the highest time of 2298 seconds to train the model and the simple customized model (sCNN) took the lowest time of 200 seconds to train the model.
3	Khandaker Foysal Haque et al / 2020	<ul style="list-style-type: none"> The proposed sequential CNN model from scratch provided better accuracy when trained with the relevant medical dataset than the pre-trained models that are trained 	<ul style="list-style-type: none"> The model was trained with a limited dataset. 	<ul style="list-style-type: none"> Due to its simpler architecture, the model is computationally efficient.

Because there are more datasets available for X-ray pictures than other medical imaging types, numerous researchers have used them to train the CNN model to identify COVID-19. Sample X-ray pictures of a) Normal cases and b) COVID-19-positive cases from the COVID-19 dataset

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

are shown in Fig. 4. We briefly describe the application of deep learning approaches in recently suggested systems for detecting COVID-19 from X-rays.

Fig 4. Sample X-ray images of a) Normal cases b) COVID-19 positive cases

The use of CT imaging in COVID-19 early detection is beneficial. It is used because it offers a three-dimensional image of the lung that includes specific information about the damaged area.

4. CONCLUSIONS

The role of the two medical imaging techniques X-rays and CT, in the detection of COVID-19, is described briefly. Though X-ray imaging is simple, less expensive, and widely available, CT imaging is highly sensitive in predicting the severity of the disease. Due to the X-ray image dataset's wide availability compared to the CT image dataset, most researchers have utilized chest X-ray images to detect COVID-19. A comparison has been made for the state-of-the-art methods that could guide young researchers to find future direction. Models proposed for binary and multiclass classification are studied, and observed that the models produced better accuracy for binary classification than multiclass classification. Accuracy, Specificity, Precision, Recall, F1-score, ROC curve (Receiver Operator Characteristic), and AUC (Area Under the Curve) are the standard metrics to evaluate the model's performance.

ABSTRACT

The flow characteristics changes with varying geometry of hydraulic weir and how the weir is inclined to the direction of flow in a channel. In this way, several studies have investigated the performance weirs experimental with paying much attention on the accurate prediction of discharge coefficient. Thus, the main objective of this study is to employ artificial intelligence (AI) techniques to predict discharge coefficient (C_d) of crump weir models. Hence, the precision and use of seven data-driven models including Bayesian neural network (BNN), multiple linear regression (MLR), multi-layer perceptron neural network (MLPNN), genetic algorithm (GA), support vector machine (SVM), Radial Basis Function (RBF) and curve fitting neural network (CFNN) were examined for estimating of the C_d . To achieve this, experiments were conducted on eighteen crump weir models of different apex angles 80° , 90° , 100° , 110° , 120° and 130° . The upstream angles of the weir models were set in decreasing order of 85° , 70° , 55° , 40° , 25° and 10° . While the downstream angles were increased as 15° , 20° , 25° , 30° , 35° and 40° respectively. 360 laboratory test results were used, 70% for training, 15% for testing and 15% for validation. And statistical parameters of coefficient of determination (R^2), root-mean-square error (RMSE), mean absolute error (MAE), were employed as the criteria for the comparison of the models' performance. Results showed good agreements between the observed and estimated

values using the AI-based models. However, among these models, the CFNN managed to estimate the C_d of the weir with the highest precision and accuracy than the rest of the models with ($RMSE=0.1635 \times 10^{-4}$, $R^2=0.9981$). Also, it was found that the most efficient crump was weir model 17 for having the least C_d of 1.14914 and least percentage error of 12.97412, which has been optimized using GA with C_d value of 1.14815.

Keywords: Crump Weir, Discharge Coefficient, Channel, Experiments, Artificial Intelligence.

1. INTRODUCTION

The Crump section *flat-vee* weir is favored by hydrometrics because of the accuracy and range of flow measurement it exhibited. It is comparatively insensitive to submerged conditions and ease of determination of flow curves for any width, and its coefficient of discharges remain through undrown condition. However, this type of weir is disliked by fishermen because it can present a barrier to migration of fish (Rickard *et.al.*2003). As such it becomes necessary to investigate the behavior of the flow over the crump weir. In this way, few studies have been devoted to evaluating the flow over crump weirs, for example, Bos,1989 was the first to study the flow characteristics of trapezoidal profile weirs systematically. He conducted a series of experiments on these types of weirs with both upstream and downstream side slopes. The discharge coefficient was determined for free flow conditions using different discharge values. Also, Al-Naely *et al.*, 2018 placed crump weirs in a channel as a control device in order to the flow rate, a new performance for the crump weirs was observed as a result of adding an opening holes in the model of crump weir. The opening holes act as energy dissipaters and improves for the discharge coefficient (C_d), where higher values of the discharge coefficient (C_d) were recorded in comparison with conventional weir under the same laboratory conditions. In the same vein, the creation of an opening in a broad-crested weir was found to increase the discharge coefficient and consequently improving the discharge (Daneshfaraz et al. 2019). Similarly, Khalifa & Umar, 2018 conducted experiments on crump weir models of different apex angles, they demonstrated that increase in the apex angle resulted in decrease in discharge coefficient. Hence, controlling the amount of discharge over different hydraulic structures was always a field of interest for researchers, with a view of decreasing sedimentation in reservoirs (Zahabi et al., 2018).

2. THEORETICAL BACKGROUND

2.1. Governing Equations

The discharge was estimated using the equation governing the modelling of flow over crump weir by determining the upstream flow head (h). Point gauge was used to measure the, h , above the crump weir (Arora, 2005). Thus, for modular flow over the crump weir, when the weir operates undrowned, the modular discharge is expressed as follows:

$$Q_m = C_d \sqrt{g} \cdot b H_o^{\frac{3}{2}} \quad (1)$$

C_d and H_o can be determined using Equations (2) and (3) respectively

$$C_d = 1.163 \left(1 - \frac{0.0003}{h} \right)^{1.5} \quad (2)$$

$$H_o = y_o + \frac{v_o^2}{2g} \quad (3)$$

Where, Q_m = Discharge for modular flow (m^3/s), C_d = Modular discharge coefficient, g = gravity (m^2/s), b = Breadth of weir (m), H_o = Total head upstream of the weir crest (m), y_o = upstream water level (m), $\frac{V_o^2}{2g}$ = upstream velocity head (m).

However, for non-modular flow, when the weir operates drowned, a single measurement of upstream head is not sufficient to calculate the actual flow as the upstream head is affected by changes in the downstream head. In this case, a dimensionless reduction factor is introduced to correct the non-modular flow as given by Equation (4):

$$f = Q/Q_m \tag{4}$$

Where, Q = Discharge for non-modular flow (m^3/s)

2.2 Artificial Neural Networks

Artificial neural network (ANN) is a nonlinear mathematical model that is able to simulate arbitrarily complex nonlinear processes, which relate inputs and outputs of any system. In many complex mathematical problems that lead to solving complex nonlinear equations, multilayer perceptron networks are common types of ANN widely used by researchers (Parsaie 2016; Moazamnia et al. 2019).

2.3 Support Vector Machines

Support vector machines operate based on data mining algorithms and are like other artificial intelligent methods. It was used in different fields of hydrology (e.g., Nadiri et al. 2017) and Hydraulics (e.g., Sadeghfam et al. 2019). Support vector machines are an efficient learning system based on the theory of optimization that uses the inductive principle of minimization of structural errors and lead to a general optimal response.

2.4 Multi-layer Perceptron Neural Network (MLPNN)

MLPNN is a computational method which tries to propose a mapping between input space (input layer) and optimal space (output layer) by understanding the inherent relationships among data with the help of learning process and using simple processors called neurons (Heidari *et al.*, 2016). The high speed of processing and flexibility in the face of unwanted errors are the features of this model. Its main advantage is its high speed and optimal precision in the prediction of complex variables with linear and non-linear mapping.

2.5 Multiple Linear Regression (MLR)

MLR is the most common regression which is employed to create a linear relationship between a dependent variable such as y and a set of independent variables such as $x_1, x_2, x_3, \dots, x_n$ [J.P. Resop, 2006]. The linear equation of this method is in the form of Equation (3.10).

$$y = +b_0 + b_1 x_1 + b_2 x_2 + \dots \tag{3.10}$$

. The performance and precision of regression methods highly depend on the sample size, and sample size can limit statistical models [Ghorbani et al, 2017].

2.6 Multilayer Perceptron (MLP)

Multilayer perceptron (MLP) network is the most commonly used neural network model applied in water engineering issues; for training, this network, a back-propagation learning algorithm which is a learning method with an observer, is used. The purpose of training a neural

network is to arrange the network parameters (weights and biases) by providing training patterns, in a way that by representing the same patterns, the resulted error between the optimal response and network is minimized.

Mohammad Zounemat *et al.*, 2019 have examined the precision and use of six data driven models including BNN, MLR, MLPNN, GEP, LSSVM and CHAID for estimation of discharge passing triangular Arced labyrinth weir. MLPNN managed to estimate the discharge passing the weir with the highest precision (RMSE = 0.00385, $R^2 = 0.999$).

Reza Norouzi *et al.*, 2019 have investigated the performance of MLP, RBF and SVM in predicting the discharge coefficient (C_d) of lybrinth weirs. The performance of the MLP model was excellent with RMSE and R^2 of 0.019 and 0.985 respectively.

In the studies of Zounemat *et al.*, 2019, they applied various hybrid meta-heuristic MLPNN and ANFIS for predicting flow parameters of piano key weir flow.

3. METHODOLOGY

3.1 Fabrication of the Experimental Models

The experimental work was conducted on eighteen crump weir models of different apex angles of 80° , 90° , 100° , 110° , 120° and 130° . Accordingly, the upstream angles of the models were decreased to have the following values 85° , 70° , 55° , 40° , 25° and 10° , and to as well increasing the downstream angles as 15° , 20° , 25° , 30° , 35° and 40° respectively, which will sum up to give 180° as the total angles in a triangle as shown in Figure 1. Plywood of 22 mm thickness was used in fabricating the main body of the crump weirs.

Figure 1: The schematic view of crump weir model 1 of apex angle 80° , upstream angle and slope, 85° and 0:1, downstream angle and slope, 15° and 4:1 respectively.

Table 1. Geometric factors of crump weir models

Model	Upstream Slope	Downstream Slope	Model width 'b' (cm)	Crest Height 'P' (cm)	Apex Angle (degree)	Upstream Angle(degree)	Downstream Angle(degree)
1	0.1:1	4:1	30	15	80	85	15
2	0.4:1	3:1	30	15	90	70	20
3	0.7:1	2:1	30	15	100	55	25

4	1:1	2:1	30	15	110	40	30
5	2:1	1:1	30	15	120	25	35
6	6:1	1:1	30	15	130	10	40

Figure 2: Sketch of crump weir model and experimental flume.

3.2 Experimental Procedure:

The crump weirs were installed in the flume with the help of sealants to prevent leakage, which has to be levelled. One vernier were located downstream the weir and the other upstream. The verniers were zeroed with the bed of the channel.

Seventy-two models were fabricated for which the angles were varied, 80°, 90°, 100°, 110°, 120°, and 130°

Experiment were then be ran for each model and various heads and their corresponding discharges were recorded; The procedure has five (5) runs. Each run has a different flow rate and a set of four (4) y_o and y_l depths; two sets for modular flow condition and the other two sets for non-modular flow condition. The initial flow rate were set. Then, y_o and y_l depths were recorded for the following conditions: Modular flow: without stop block (gate). Modular flow: one full stop block (gate) (y_l should be the only depth that changes). Non-modular flow: Add a half of one stop block (gate). (y_l and y_o depth that change). Non-modular flow: Add one quarter of a stop block (gate). The flow rate were increased at constant interval.

Modular Flow

Figure 5. Crump weir during modular flow condition

Non-Modular Flow

Figure 6. Crump weir during non-modular flow condition

Heights ($P=10\text{cm}$, 15cm , 20cm) were used as a crump weir models. For each type of crump three types of surface roughness were used. The first one were a smooth PVC, the second one is coated with a uniform sand $D_{50}=0.72\text{ mm}$ (D_{50} is the sieve diameter in which 50% of material are finer), while the third is covered by gravel of $D_{50}=3.6\text{ mm}$. Eighteen models were used to conduct the experimental study. In each run the selected model were inserted along the width of the flume. Then the pump started at desired flow rate and after the flow stability were achieved the water surface level upstream and above the weir model were measured using point gauge. For each type of the crump weir a series of tests under different flow rates were conducted. The pump were activated and the discharge were adjusted using a control valve and the reading of the point gauge were recorded to give the head above crump weir required for the calculation of estimated discharge; At the beginning of each run the control valve were adjusted to alter the head; For each head recorded, the actual discharge were measured by direct method using the weighing arrangement provided at the tail end of the flume. The previous steps were repeated for each of the five runs of experiments to be conducted for each model. A total of 360 runs were conducted.

3.3 Determination of Observed Discharge (Q_o)

The observed discharge, Q_o , was measured experimentally using the gravimetric method. Throughout the experiment, 100kg of water were collected by means of the weighing balance (see plate II) attached to the flume and stopwatch was used to obtain the time taken to collect the 100kg for onward determination of discharge.

Volume, $V = \text{mass}/\text{density}$

Observed discharge, $Q_o = \text{Volume} / \text{average time}$

$$\text{Average time} = \frac{(t_1 + t_2)}{2} \quad (5)$$

3.4 Determination of Estimated Discharge (Q_e)

The discharge equation for the crump weir was used to compute the estimated discharge using the flow heads.

Point gauge will be used to measure the flow head (h) above the crump weir (Arora, 2005).

$$Q_m = C_d \sqrt{g} \cdot b H_o^{\frac{3}{2}} \quad (1)$$

$$C_d = 1.163 \left(1 - \frac{0.0003}{h} \right)^{1.5} \quad (2)$$

$$H = y + \frac{v^2}{2g} \quad (3)$$

3.6 Derivation of Discharge Coefficient

In order to validate the suitability of the theoretical equations, the maximum of the absolute value of the deviation of the data from the model was obtained as:

$$\text{MaxErr} = \max(\text{abs}(C_{do} - C_{de})) \quad (7)$$

Where, C_{do} = Experimental Discharge Coefficient = Q_o / Q_e

C_{de} = Estimated Discharge Coefficient

$$Cd = (D_{50}, P, h, Q, \theta) \quad (8)$$

Thus, by dimensional analysis and using the approach of Buckingham's π -theorem, Equation (8) becomes:

$$Cd = f\left(\frac{D_{50}}{P}\theta, \frac{h}{P}\right) \quad (9)$$

It follows that Equation (9) can be expressed as Equation (10) based on dimensional homogeneity:

$$C_d = k_1 \left[\frac{D_{50}\theta}{P}\right]^a + k_2 \left[\frac{h}{P}\right]^b \quad (10)$$

Where, K_1 , K_2 , a , and b are parameters to be estimated by regression analysis.

4. RESULTS AND DISCUSSION

4.1 Computation of Discharge Coefficients (C_d)

Tables 2 show the values of C_d obtained from Equations 1 and 2 respectively. The head measurements were obtained by means of the point gauge.

4.2 Discussion of Result:

Variation of Cd with (h/P)

The dimensional analysis for the variables affecting Cd value of weirs shows that the value (h/p) (Where h is head of the water on the weir, P height of the weir), has a greatest influence on Cd value. The calculated values of h/P are plotted against the Cd values for each weir and for each surface roughness's as shown in Figure 9. The figure shows that Cd value increase with increasing in h/P values for all the cases. Also it's evident from these figures that the gradient of the curve fit the points are decrease with increase in weir height, this means that the effect of h/P on Cd values will increase with increase in weir height.

Predicting the Cd of crump weir using ANN

Results of evaluating the precision of the data-driven models in the estimation of Cd of crump weirs in the training and testing sets are presented in Tables 5 and 6 respectively. Comparison of the values provided in Table 6 shows that CFNN managed to estimate discharge passing the weir with the highest accuracy (RMSE= 0.1635×10^{-6} MAE= 0.4713×10^{-3} $R^2 = 0.9981$). Also, CFNN was followed by MLPNN, BNN, GA, MLR, RBF and SVM.

Eqs. (15) demonstrate the extracted relationships between independent and dependent variables in the CFNN model. Scatter plots presented in Figs. 14 and 15 show the results of BNN and MLPNN respectively indicating their good precision in estimating the performance of the crump weir.

In this study, the precision of seven data-driven models was evaluated for the estimation of Cd for crump weir. Final results showed that CFNN could estimate the discharge passing the weir with the highest precision. Also, due to the effect of input parameters of the model on the estimation accuracy, CFNN precision was evaluated using the various combination of the input parameters. 2 different independent variables were used for constructing the applied models. In order to investigate the importance of each variable in the final performance of the models.

Table 7 shows the sensitivity analysis of Coefficient of discharge, Cd. The sensitivity analysis was carried, in order to evaluate the significance of input variables on the Coefficient of discharge. The sensitivity analysis was performed using the ANN model due to the high value of correlation coefficient and minimum error it produced.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Consequently, the parameter ($\frac{h}{P}$) was found to be the most effective parameter with $R = 0.9971$, $MSE = 3.8513 \times 10^{-4}$ on the prediction of Cd. While the function ($\frac{D_{50}\theta}{P}$) was found to be the least effective parameter on the prediction of Cd.

Figure 8. ANN verification of Cd from model equation

Table 5. Results of evaluating the performance of data driven models in the training phase.

Models	MSE $\times(10^{-6})$	MAE $\times(10^{-3})$	R ²
MLP	8.1825	0.9874	0.9234
BNN	7.9003	0.8452	0.9192
RBF	2897.6	1.7652	0.8400
SVM	4232.7	2.6745	0.7300

Table 6. Results of evaluating the performance of all the applied models in the testing phase.

Models	MSE $\times(10^{-6})$	MAE $\times(10^{-3})$	R ²
CFNN	0.1635	0.4713	0.9981
MLP	1.8738	0.6704	0.9821
BNN	3.4682	0.7461	0.9669
GA	3.9641	0.8452	0.9573
MLR	2611.7	1.4233	0.8700
RBF	2672.6	1.5712	0.8600
SVM	3288.7	2.1005	0.7900

Finally, the precision of the models in estimating the discharge passing the weir was evaluated using the root-mean square error (RMSE), mean absolute percentage error (MAE), R² (coefficient of determination). The best values of these criteria were 0, 0, and 1 respectively.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

$$RMSE = \sqrt{\frac{1}{n} \sum_{j=1}^n (y_j - \hat{y}_j)^2} \quad (12)$$

$$MAE = \frac{1}{n} \sum_{j=1}^n |y_j - \hat{y}_j| \quad (13)$$

$$\hat{R}^2 = 1 - \frac{\sum_{i=1}^n (Y_i - \hat{Y}_i)^2}{\sum_{i=1}^n (Y_i - \bar{Y})^2} = 1 - \frac{\frac{1}{n} \sum_{i=1}^n (Y_i - \hat{Y}_i)^2}{\frac{1}{n} \sum_{i=1}^n (Y_i - \bar{Y})^2} \quad (14)$$

In Eqs. (12)–(14), y is the actual Cd, \hat{y} is their average, n is the number of estimations.

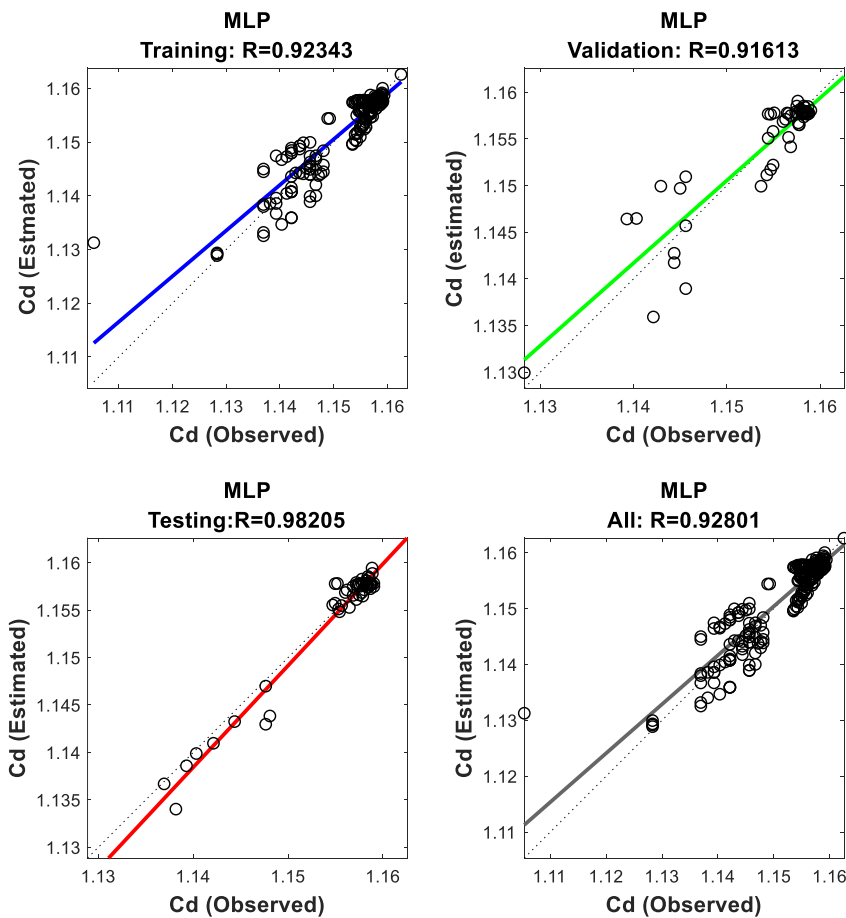

Figure 15. Distribution diagram of the observational-computational values in training and testing stages of MLP model

Thus, the parameters K_1 , K_2 , a and b in Equation (10) were determined through regression analysis and Curve Fitting Neural Network as expressed by Equation (15) as follows:

$$Cd = 0.5785 \left[\frac{D_{50}\theta}{P} \right]^{6.593 \times 10^{-5}} + 0.58 \left[\frac{h}{P} \right]^{0.006761} \quad (15)$$

The model equation has $R^2 = 0.9981$.

Table 7. Sensitivity analysis of Cd's for input parameters with ANN model.

Function	Training		Testing	
	MSE $\times (10^{-4})$	R^2	MSE $\times (10^{-4})$	R^2
$Cd = \left[\frac{D_{50}\theta}{P} \right]$	7.5421	0.9782	7.6801	0.9884
$Cd = \left[\frac{h}{P} \right]$	3.7313	0.9841	3.8513	0.9971

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

$$Cd = \left(\frac{D_{50}}{P} \theta, \frac{h}{P} \right) \quad 0.1534 \quad 0.9883 \quad 0.1635 \quad 0.9981$$

Table 7 shows the sensitivity analysis of Coefficient of discharge, Cd. The sensitivity analysis was carried, in order to evaluate the significance of input variables on the Coefficient of discharge. The sensitivity analysis was performed using the ANN model due to the high value of correlation coefficient and minimum error it produced.

Consequently, the parameter $\left(\frac{h}{P} \right)$ was found to be the most effective parameter with R = 0.9971, MSE = 3.8513×10^{-4} on the prediction of Cd. While the function $\left(\frac{D_{50}\theta}{P} \right)$ was found to be the least effective parameter on the prediction of Cd.

Figure 16. Relation of predicted Cd and observed Cd using (MLP) model

5. CONCLUSION and RECOMMENDATIONS

By using the equations which have been discussed in the literature, the raw data was calculated and processed using ANN.

Based on the results of the investigation, the following conclusions are reached:

1. Cd increases with the increasing flow rate.
2. The effect of h/P on Cd values increases with the increase in weir height. .
3. The effect of the increase of surface roughness on h values will be more on small heights of the crump weir than large ones.
4. Cd decreases from model 1 to model 18 with model 17 having the least Cd close to unity and least percentage error making model 17 to be more efficient.
5. Cd is dependent on the upstream angle, apex angle and downstream angle of the weir. As the upstream angle decreases from 85° to 10°, apex angle increases from 80° to 130° and the downstream angle increases from 15° to 40° the Cd decreases.
6. The Mathematical Model equation generated using CFNN performed better than other models such as MLP, BNN, GA, MLR, RBF and SVM with RMSE= 0.1635×10^{-6} MAE= 0.4713×10^{-3} R²=0.9981

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

7. The model was optimised using GA and the predicted Cd value was 1.14815 as best fitted value.

The recommendations below are some of the improvements that can be carried out for further study:

1. Depth of weir and width of channel in variable value are suggested to get the best flow rate for hydraulic structure of crump weir design.
2. Calibration device for better data collection suggested using a volume meter to get the flow rate over a crump weir.
3. Similar study should be carried out using stones and cement models instead of wooden models.

ABSTRACT

MoS₂ (molybdenum disulfide) nanomaterials have emerged as promising candidates for photocatalytic applications due to their unique structural and electronic properties. This abstract highlights the recent advancements in the synthesis, characterization, and photocatalytic performance of MoS₂ nanomaterials for efficient solar energy conversion and environmental remediation. The synthesis of MoS₂ nanomaterials involves various techniques such as chemical vapor deposition, hydrothermal synthesis, and solvothermal methods. These techniques allow precise control over the size, morphology, and crystallinity of the nanomaterials, which significantly influence their photocatalytic properties. Moreover, surface engineering and doping strategies have been explored to enhance the photocatalytic activity and stability of MoS₂ nanomaterials. Characterization techniques, including transmission electron microscopy, X-ray diffraction, and spectroscopic methods, have been employed to analyze the morphology, crystal structure, and surface chemistry of the synthesized MoS₂ nanomaterials. These studies provide valuable insights into the structure-property relationships governing the photocatalytic performance. MoS₂ nanomaterials exhibit excellent photocatalytic activity for various reactions, including water splitting, hydrogen evolution, carbon dioxide reduction, and organic pollutant degradation. The unique electronic band structure of MoS₂, with a direct bandgap in the visible range, enables efficient light absorption and charge separation. Additionally, the high surface area and abundant active sites on the nanomaterials facilitate enhanced reaction kinetics.

Keywords: MoS₂ Nanomaterials, Standardization, Molybdenum, Pharmaceuticals, Biocompatibility, Semiconductor.

1. INTRODUCTION

1.1 Definition

The prefix 'nano' is referred to a Greek prefix meaning 'dwarf' or something very small. Nano materials must have at least one dimension that is less than approximately 100 nanometers. According to the International Organization for Standardization (ISO), the prefix nano refers to a size ranging approximately from 1 to 100 nm. As a comparison, the diameter of a carbon atom

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

is about 0.25 nm, and the distance between carbon atoms is 0.15 nm. Nanomaterials are thus larger than single atoms or even small groups of atoms (Bayda et al., 2019).

1.2 History

The use of nanotechnology is far from being new. For example, it was used around 2600 BC in dyes to impart color to fibers and fabric. Another example can be found in Middle Age churches, where stained glass artisans utilized nanoscopic scale (or nanoscale) gold and silver particles to impart ruby red and deep yellow color to window panels. Another example is the Damascus steel produced by the twelfth to the eighteenth century Middle Eastern metal smiths, which includes cementite nanowires inside carbon nanotubes. At that time, they had no way to observe the nanostructures they created. More recently, carbon black has been employed since 1910 to reinforce tires, without knowing that it was the interaction between rubber and the nanoscale carbon black particles that imparted the tires with increased hardness, strength, abrasion, and tear resistance. (Bayda et al., 2019).

1.3 The Imaginative Pioneers of Nanotechnology

The American physicist and Nobel Prize laureate Richard Feynman introduced the concept of nanotechnology in 1959. During the annual meeting of the American Physical Society, Feynman presented a lecture entitled "There's Plenty of Room at the Bottom" at the California Institute of Technology (Caltech). In this lecture, Feynman made the hypothesis "Why can't we write the entire 24 volumes of the Encyclopedia Britannica on the head of a pin?", and described a vision of using machines to construct smaller machines and down to the molecular level. This new idea demonstrated that Feynman's hypotheses have been proven correct, and for these reasons, he is considered the father of modern nanotechnology. After fifteen years, Norio Taniguchi, a Japanese scientist was the first to use and define the term "nanotechnology" in 1974 as: "nanotechnology mainly consists of the processing of separation, consolidation, and deformation of materials by one atom or one molecule".

After Feynman had discovered this new field of research catching the interest of many scientists, two approaches have been developed describing the different possibilities for the synthesis of nanostructures. These manufacturing approaches fall under two categories: top-down and bottom-up, which differ in degrees of quality, speed and cost.

The top-down approach is essentially the breaking down of bulk material to get nano-sized particles. This can be achieved by using advanced techniques such as precision engineering and lithography which have been developed and optimized by industry during recent decades. Precision engineering supports the majority of the micro-electronics industry during the entire production process, and the high performance can be achieved through the use of a combination of improvements. These include the use of advanced nanostructure based on diamond or cubic boron nitride and sensors for size control, combined with numerical control and advanced servo-drive technologies. Lithography involves the patterning of a surface through exposure to light, ions or electrons, and the deposition of material on to that surface to produce the desired material. The bottom-up approach refers to the build-up of nanostructures from the bottom: atom-by-atom or molecule-by-molecule by physical and chemical methods which are in a nanoscale range (1 nm to 100 nm) using controlled manipulation of self-assembly of atoms and molecules. Chemical synthesis is a method of producing rough materials which can be used either directly in product in their bulk disordered form, or as the building blocks of more advanced ordered materials. Self-assembly is a bottom-up approach in which atoms or

molecules organize themselves into ordered nanostructures by chemical-physical interactions between them. Positional assembly is the only technique in which single atoms, molecules or cluster can be positioned freely one-by-one. Nano-materials can be classified according to their source, their dimensions, and their constitutive materials. Here we discussed MoS₂ nano-materials (Bréchnac, et al., 2008).

1.4 MoS₂

It is the mostly studied and best known representative of the transition metal dichalcogenides, a famous group of 2D materials. It consists of a sandwich structure out of three atomic layers as shown in **Fig. 1**. The layer of molybdenum atoms (black) is encapsulated by two layers of sulfur atoms (yellow). Strong covalent bonding between sulfur and molybdenum atoms forms the backbone of such a three-layered structure, also referred to as a single-layer MoS₂ (Jaleel et al., 2022).

MoS₂ is a black-colored substance, insoluble in water, and like graphene, has a layered structure. It is mostly found in nature in the form of molybdenite MoS₂ has excellent thermal and chemical stability, which is a feature of layered transition metal compounds in general. As a result, it is employed in nanochemistry, catalysis, electrode materials, pharmaceuticals, nanomedical transportation, etc. MoS₂ is a typical n-type semiconductor with a layered structure that is quite similar to graphene. The band gap of MoS₂ grows as the number of the atomic layers decreases, resulting in desirable photoelectric characteristics. It is a semiconductor of the MX₂ type, where M stands for transition metals and X is for chalcogen. A single sheet is similar to a “sandwich” structure, where the Mo atom is sandwiched between two S atoms. MoS₂ layers, separated by 0.65 nm, are held together by van der Waals forces, and the layers are bound together by strong covalent bonds. Figure 2a.b show the crystal structure of MoS₂.

Fig1. MoS₂ structure three atomic layer.

Figure 2. (a) Three dimensional representation of the structure of MoS₂. Single layers, 6.5 Å thick, can be extracted using scotch tape-based micromechanical cleavage. (b) Optimized structures of MoS₂ monolayer with four adsorption sites: (1) hollow site, (2) top site of the S atom, (3) Mo–S bridge site, and (4) top site of the Mo atom.

MoS₂ structure is a trigonal prismatic of S–Mo–S arrangement having two atomic planes of S surrounding an atomic plane of Mo in a sandwich-like structure. The length of the Mo–S bond is 1.54 Å, while the S–S bond is 3.08 Å in length. Accordingly, the MoS₂ single-layer thickness is about 0.62 nm. The MoS₂ semiconductor has an indirect bandgap of 1.2 eV. While the direct bandgap of a single-layered MoS₂ semiconductor is 1.8 eV. In addition, although multilayer MoS₂ is not photoluminescent, exfoliation-induced changes in its electronic structure lead to photoluminescent behavior in exfoliated monolayers. MoS₂ has three main phases 1 T MoS₂, 2H MoS₂ and 3R MoS₂. In the 1 T MoS₂ unit cell, the sulfur atoms coordinate the molybdenum atoms octahedrally 2H MoS₂ has the molybdenum atom coordinated by two S–Mo–S units in a trigonal prismatic geometry for each elemental cell; and with the same geometry as the 2H MoS₂, coming to the third phase the 3R MoS₂ but three units of S–Mo–S are directed along the c-axis instead of two. The 1 T phase has metallic properties, while the 2H and the 3R phases are semiconductors. Natural MoS₂ exists as the thermodynamically favored 2H phase, while the 1 T phase does not occur naturally and is usually obtained from lithium-intercalated 2H-MoS₂ interlayers by chemical exfoliation. Furthermore, the mono-layered 1 T-MoS₂ is metastable from the thermodynamic perspective, which tends to restructure to form the more stable phase, 2H-MoS₂. Consequently, the 1 T phase commonly happens in a multiphase form along with the 2H phase (He & Que, 2016).

Generally, molybdenum disulfide has very good chemical stability and thermal stability. They can form a highly efficient dry lubricating film. Molybdenum disulfide nanoparticles possess a low friction coefficient, good catalytic activity, and excellent physical properties. They also have a large active surface area, high reactivity, and increased adsorption capacity compared to the bulk material. Molybdenum disulfide nanoparticles appear in a black solid form.

1.5 Chemical Properties

The chemical properties of molybdenum disulfide nanoparticles are outlined in the following table.

CAS No.	1317-33-5		
Group	Molybdenum Sulfur 16		
Electronic configuration	Molybdenum	[Kr]	4d ⁵ 5s ¹
	Sulfur [Ne] 3s ² 3p ⁴		

Chemical Composition

Element	Content (%)
Molybdenum	59.94
Sulfur	40.05

1.6 Physical Properties

The physical properties of molybdenum disulfide nanoparticles are given in the following table.

Properties	Metric	Imperial
Density	5.06 g/cm ³	0.182 lb/in ³
Molar mass	160.07 g/mol	-

1.7 Thermal Properties

The thermal properties of molybdenum disulfide nanoparticles are provided in the table below.

Properties	Metric	Imperial
Melting point	1185°C	2165°F

1.8 MoS₂ based nanomaterials

MoS₂ based nanomaterials are discussed in a comprehensive way. Nanomaterials based on MoS₂ such as MoS₂ based nanomaterials, MoS₂ nanosheets, MoS₂ QD and MoS₂ nanoflowers. (Yadav et al., (2019).

a. MoS₂ based nanostructures

MoS₂ shows many properties including strong visible light absorption, biocompatibility, fluorescence quenching properties and many other interesting properties. Band gap of MoS₂ is greatly influenced by its thickness, 1.2 eV for bulk material and 1.8 eV for single layer therefore it has distinctive light response properties from ultraviolet to NIR light. The piezoelectric property, catalytic activity and band gap of MoS₂ can be tuned by modifying its phase, structure, size and doping with other materials. MoS₂ crystal displays 1T, 2H and 3R polytype formats, in which 2H is the most stable form. All of these excellent properties make MoS₂ an elegant material in numerous fields like opto-electronics, biomedical, dry-lubricants, catalysis, energy,

environmental, sensing, etc. MoS₂ can form various morphologies like nanoplates, nanowires, nanotubes, nanorods, nanoflowers and quantum dots (Yadav et al., (2019).

b. MoS₂ nanosheets

In MoS₂, atomic layer of molybdenum is sandwiched between the two sulphide atomic layers through strong covalent bonds. The weak van der Waals forces existing between the adjacent layers are responsible for the production of single or few layered MoS₂ nanosheets from bulk three dimensional crystalline MoS₂. Consequently, application of mechanical forces help to overcome this van der waal forces which lead to the formation of monolayer MoS₂ nanosheets with a thickness of 6.5 Å. Quantum confinement plays a major role in the outstanding properties shown by the exfoliated MoS₂ nanosheets when compared to bulk MoS₂. Nanosized MoS₂ has much active site than bulk MoS₂ due to its direct band gap whereas the bulk material has indirect band gap. In spite of all these advantages, it is very difficult to obtain MoS₂ nanosheets due to its low yield, instability and expensive nature. Mechanical exfoliation, chemical vapour deposition (CVD), chemical exfoliation and liquid phase exfoliation (LPE) are the most common methods used for MoS₂ nanosheet synthesis (Yadav et al., (2019).

c. MoS₂ quantum dots

Among numerous variety of 2D QDs, MoS₂ QDs are the most promising ones due to their attractive photoluminescence emission better biocompatibility and ease of fabrication. Zero dimensional MoS₂ QDs can be synthesized through controlling the size of MoS₂ less than 10 nm. QDs give greater number of conductive and catalytic edge sites than their 2H-MoS₂ flakes. Moreover, it has greater surface to volume ratio, tunable fluorescence emission and small size than other MoS₂ nanostructures. Because of the edge effects and quantum confinement, MoS₂ QDs hold unique electronic and optical properties. Thereby, finding numerous application in biomedical, sensors, energy and electrocatalysis. Top-down and bottom-up are the two general methods for the synthesis of MoS₂ QDs (Yadav et al., (2019).

d. MoS₂ nanoflowers

Nanoflowers are newly established nanoparticle systems showing resemblance to flowers in 100–500 nm nanoscale range. It contains many nano-sized petals to cover a greater surface area in a small structure and possess better carrier immobility and charge transfer. Moreover, surface reaction efficiency is raised in this 3D (three dimensional) nanoflower structure. Recent studies prove that, 3D MoS₂ nanosystems are anticipated to have many applications due to their notable advantages like greater aspect ratio and many active edges. Three-dimensional MoS₂ nanostructures are mainly obtained through hydrothermal synthesis. In one study, hydrothermally synthesised MoS₂ nanoflowers showed better sunlight-induced photocatalytic properties towards the degradation of methyl orange, oxytetracycline hydrochloride, methylene blue and rhodamine (Yadav et al., (2019).

1.9 Applications

Molybdenum disulfide (MoS₂) nanomaterials have been widely used in various fields such as energy store and transformation, environment protection, and biomedicine due to their unique physicochemical properties. The key applications of molybdenum disulfide nanomaterials are as follows: In lubricant applications, catalyst for coal liquefaction. It is used to prepare special materials, catalytic materials and gas storage. It's nanocomposites in cancer diagnosis, mainly

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

focusing on biosensors, bioimaging, chemotherapy, phototherapy, microwave hyperthermia, and combination therapy. Used in gas sensors. It is also used in photocatalysis.

1.10 Photocatalysis

The term photocatalyst is a combination of two words: photo related to photon and catalyst, which is a substance altering the reaction rate in its presence. Therefore, photocatalysts are materials that change the rate of a chemical reaction on exposure to light. This phenomenon is known as photocatalysis. Photocatalysis includes reactions that take place by utilizing light and a semiconductor. The substrate that absorbs light and acts as a catalyst for chemical reactions is known as a photocatalyst. All the photocatalysts are basically semiconductors. Photocatalysis is a phenomenon, in which an electron-hole pair is generated on exposure of a semiconducting material to light. The photocatalytic reactions can be categorized into two types on the basis of appearance of the physical state of reactants (Ameta et al., 2018).

Homogeneous photocatalysis: When both the semiconductor and reactant are in the same phase, i.e. gas, solid, or liquid, such photocatalytic reactions are termed as homogeneous photocatalysis.

Heterogeneous photocatalysis: When both the semiconductor and reactant are in different phases, such photocatalytic reactions are classified as heterogeneous photocatalysis.

Photocatalysis processes takes place under light irradiation in the presence of photocatalyst. Nanomaterials in photocatalysis were investigated as smart materials for water purification systems due to the excellent surface area and morphological properties. Molybdenum disulfide (MoS_2) and its variants exhibit high photocatalytic activity under irradiation by visible light as well as good stability and recyclability, which are desirable for all photocatalytic applications.

2. REVIEW OF LITERATURE

Peng *et al.* (2014) investigated that a novel molybdenum disulfide (MoS_2) and graphitic carbon nitride ($\text{g-C}_3\text{N}_4$) composite photo-catalyst was synthesized using a low temperature hydrothermal method MoS_2 nanoparticles formed on $\text{g-C}_3\text{N}_4$ nano-sheets greatly enhanced the photo-catalytic activity of $\text{g-C}_3\text{N}_4$. The photo-catalyst was tested for the degradation of methyl orange (MO) under simulated solar light. Composite 3.0 wt% $\text{MoS}_2/\text{g-C}_3\text{N}_4$ showed the highest photo-catalytic activity for MO decomposition. MoS_2 nanoparticles increased the interfacial charge transfer and thus prevented the recombination of photo-generated electron-hole pairs. The novel $\text{MoS}_2/\text{g-C}_3\text{N}_4$ composite was therefore shown as a promising catalyst for photocatalytic degradation of organic pollutants using solar energy. (Peng, and Li, 2014).

Li *et al.* (2019) investigated that MoS_2 -based photocatalysts attracted wide attention as they possessed a suitable band gap for visible-light harvesting, made it a promising earth-abundant photocatalyst for hydrogen production, environmental remediation, and photosynthesis. However, the rapid recombination of photo-generated electron-hole pairs, limited quantity of active edge sites, and difficult photocatalyst separation and recycling hinder the practical application of this material. In their review, recent development of MoS_2 -based photocatalysts in various photocatalytic applications was summarized. In addition, possible approaches to enhance photocatalytic activity and separate photocatalysts from reaction media were discussed to provide a future direction in highly efficient photocatalyst design (Li *et al.*, 2019).

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Shah *et al.* (2022) demonstrated that Molybdenum disulfide (MoS_2), with a two-dimensional (2D) structure, had attracted huge research interest due to its unique electrical, optical, and physicochemical properties. MoS_2 had been used as a co-catalyst for the synthesis of novel hetero-junction composites with enhanced photo-catalytic hydrogen production under solar light irradiation. They briefly highlighted the atomic-scale structure of MoS_2 nano-sheets. The top-down and bottom-up synthetic methods of MoS_2 nano-sheets was described. Additionally, they discussed the formation of MoS_2 hetero-structures with titanium dioxide (TiO_2), graphitic carbon nitride (g-C₃N₄), and other semiconductors and co-catalysts for enhanced photo-catalytic hydrogen generation. Their review addressed the challenges and future perspectives for the enhancement of solar hydrogen production performance in hetero-junction materials using MoS_2 . (Shah *et al.* 2022).

Wu *et al.* (2018) examined that photocatalytic degradation was an emerging, efficient and energy-save technology for the removal of organic contaminants from the water environment. With the development of two-dimensional functional materials, molybdenum disulfide (MoS_2) had become one of the most popular emerging co-catalysts due to its high photo-catalytic activity, strong adsorbability, low cost and non-toxicity, especially applied to the photocatalytic degradation of organic contaminants. In their paper, they review the recent research progress of graphene, carbon-nitrogen compounds, TiO_2 and bismuth compounds supported on MoS_2 co-catalyst, which were applied to photocatalytic degradation of various organic contaminants such as methylene blue (MB), methyl orange (MO) and rhodamine B (RhB), etc. Meanwhile, the basic processes of photocatalytic degradation of organic pollutants had also been briefly analyzed and compared. More importantly, MoS_2 co-catalyst played an integral role in nanocomposites, especially in accelerating photo-induced electron transport and reducing electron recombination rates. It was indicated that MoS_2 -based composites were promising photocatalysts for photocatalytic degradation of environmental pollutants as co-catalyst. (Wu *et al.*, 2018).

Tian *et al.* (2017) investigated that the flower-like MoS_2 nanoparticles (NPs) consisted of ultra-thin MoS_2 nanosheets were synthesized via a facile one-pot hydrothermal method. The MoS_2/ZnO p-n heterostructure was formed by coating n-type ZnO on the surface of flower-like MoS_2 NPs through the seed-mediated route and post-annealing treatment. The effects for the dye removal and photocatalytic performances after ZnO coating were systematically investigated. The results demonstrated that the coating of ZnO nanoparticles had a positive promotion to the photodegrading properties while negative effect on the adsorption capacity of the MoS_2/ZnO heterostructures (Tian *et al.*, 2017).

Zhou *et al.* (2013) reported that MoS_2 nanosheet-coated TiO_2 nanobelt heterostructures referred to as $\text{TiO}_2 @\text{MoS}_2$ with a 3D hierarchical configuration were prepared via a hydrothermal reaction. The TiO_2 nanobelts used as a synthetic template inhibited the growth of MoS_2 crystals along the c-axis, resulting in a few-layer MoS_2 nanosheet coating on the TiO_2 nanobelts. The as-prepared $\text{TiO}_2 @\text{MoS}_2$ heterostructure showed a high photocatalytic hydrogen production even without the Pt co-catalyst. Importantly, the $\text{TiO}_2 @\text{MoS}_2$ heterostructure with 50 wt% of MoS_2 exhibited the highest hydrogen production rate of $1.6 \text{ mmol h}^{-1} \text{ g}^{-1}$. Moreover, such a heterostructure possessed strong adsorption ability toward organic dyes and showed high performance in photocatalytic degradation of the dye molecules. (Zhou *et al.*, 2013).

Khan *et al.* (2022) investigated that Transition metal dichalcogenides (TMDs) was promising materials for photo-catalytic functions. In class of TMDs, MoS_2 was comprehensively explored

September 14-15, 2023, Naples, Italy

as a co-catalyst due to the extraordinary activity for photocatalytic activity of organic dye degradation. But the catalytic activity of MoS_2 was generated through S ions on depiction edges. Also numerous of S ions existed on basal planes was catalytically inactive. The insertion of external metals in MoS_2 organism were extensive way for activation of basal planes surface to enhance concentration of catalytically active sites. For this purpose, nanoparticles of Nickel (Ni) doped MoS_2 was prepared by hydrothermal technique. Structural and morphological analysis was characterized by XRD and SEM, respectively. XRD results showed that Ni was completely doped into MoS_2 . SEM showed that pure MoS_2 had sheet like structure and Ni doped MoS_2 had mix disc and flower like structure. Band gap energy was observed in declining range of 2.30–1.76 eV. The photo-catalytic activity of pure MoS_2 and Ni doped MoS_2 were evaluated by degrading MB and RhB dyes under UV light irradiation. MB dye degradation of MB was 71% for pure MoS_2 . For 1% to 5% Ni doping in MoS_2 , MB dye degraded from 85% to 96%. It means that MB dye degradation of MB was enhanced continuously by increasing the concentration of Ni doping. RhB dye degradation of RhB was 62% for pure MoS_2 . For 1% to 5% Ni doping in MoS_2 , the RhB dye degraded from 77% to 91%. (Khan et al., 2022).

Lalithambika et al. (2019) investigated that transition metal dichalcogenide MoS_2 nanoparticles had been synthesized by an inexpensive slow evaporation method. The X-ray diffractogram (XRD) showed that the grown particles were in crystalline nature with mixed phase. The calculated average particle size of the prepared nanoparticles is 56 nm. The Fourier transform infra-red (FTIR) and Raman studies confirmed the particles were bulk MoS_2 in nature. Scanning electron microscope (SEM) and energy-dispersive X-ray spectroscopy (EDX) images confirmed the porosity and the presence of Mo and S elements. Photo-catalytic activity of the prepared nanoparticles were tested against methylene blue (MB), and malachite green (MG) dyes and the efficiencies were found to be 93.68% and 85.33%, respectively. The degradation rate constant of MoS_2 nanoparticle against MB and MG dyes were 0.0199, 0.01389 min^{-1} , respectively, under visible light for 75 min irradiation. A density functional theory (DFT) calculation had been performed to validate the photo-catalytic experimental results based on band-gap, band-edge potentials, and effective mass. (Lalithambika et al., 2019).

Li et al. (2019) demonstrated that a series of nanostructured molybdenum disulfide (MoS_2) with various morphologies, such as spherical, flower-like, coil and hollow were synthesized via a one-step hydrothermal method. The photo-catalytic properties of as obtained MoS_2 were evaluated by degrading methylene blue (MB) under visible light. Interestingly, the flower-like MoS_2 exhibited the best photo-catalytic activities. It was ascribed that the suitable porous structures of flower-like MoS_2 could increase the number of exposed active sites, which facilitated the efficient adsorption and transfer of MB to the active sites. Meanwhile, the special structure of flower-like MoS_2 could improve light absorption efficiency owing to the increasing of light paths. Furthermore, its 2D stacked petals possessed abundant active sites, which would effectively affect the photo-catalytic efficiency. Their study indicated that the surface area of nanomaterials was not a dominated factor in photo-catalytic performance. The surface morphology had a great influence on the photocatalytic performance, which provided a feasible guide for synthesizing efficient photocatalytic nanomaterials. (Li et al., 2019).

Rahimi et al. (2019) investigated that the few-layer exfoliated MoS_2 nanosheets were easily composited with ZnO nanorods. It was found that MoS_2 nanosheets could enhance the sunlight-induced photocatalytic activity rate of ZnO by 74%. In addition, they showed that under UV-blocked sunlight irradiation, MoS_2 weakened the photocatalytic activity rate of ZnO by 33%.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Finally, they discussed the mechanisms behind the enhanced (weakened) photocatalytic activity under sunlight (UV-blocked sunlight) irradiation based on the UV-Vis absorption and photoluminescence spectra as well as the potential band diagrams of the ZnO/MoS₂ composite. (Rahimi et al., 2019).

Putritama et al. (2020) investigated that decorating ZnO with nano-sheets of MoS₂—a transition metal dichalcogenide characterized by a relatively narrow band gap—was a promising way to increase the photo-catalytic activity of ZnO. However, limited studies reported the effect of the layer number of MoS₂ nano-sheets on the photo-catalytic performance of ZnO/MoS₂. In their work, ZnO nano-rods were decorated with multilayer and few-layer (~11 and ~3 atomic layers) MoS₂ nano-sheets exfoliated for 4 h and 8 h, respectively. This type-II heterostructures were subsequently used as photo-catalysts for the degradation of methyl blue. Their results showed that the photo-catalytic efficiency of the ZnO/ MoS₂ was less than that of pristine ZnO and it further decreased by 11% with increasing the number of layers and length of the MoS₂ nano-sheets. This effect might be due to the decrease of adsorption capacity of the water molecules on the ZnO/MoS₂ system as indicated by the increasing contact angle from 170°–230° to 730°–760°. The increase in contact angle for ZnO/MoS₂ could be due to the hydrophobic nature of the basal plane of the 2H-MoS₂ phases, which were called inactive catalytic sites. (Putritama et al. (2020).

Das et al. (2021) investigated that fabrication of heterogeneous photo-catalysts had received increasing research interest due to their potential applications for the degradation of organic pollutants in waste water and evolution of carbon-free hydrogen fuel via water splitting. Here, they reported the photo-degradation and photo-catalytic hydrogen generation abilities of nanostructured LaFeO₃-MoS₂ photo-catalyst synthesized by facile hydrothermal technique. Prior to conducting photo-catalytic experiments, structural, morphological and optical properties of the nano-composite were extensively investigated using X-ray diffraction analysis, field emission scanning electron microscopy and UV-visible spectroscopy, respectively. Nanostructured LaFeO₃-MoS₂ photo-degraded ~ 96% of Rhodamine B dye within only 150 minutes which was considerably higher than that of LaFeO₃ and commercial Degussa P25 titania nanoparticles. The LaFeO₃-MoS₂ nano-composite also exhibited significantly enhanced photo-catalytic efficiency in the decomposition of a colorless probe pollutant, ciprofloxacin eliminating the possibility of the dye-sensitization effect. Moreover, LaFeO₃-MoS₂ demonstrated superior photo-catalytic activity towards solar hydrogen evolution via water splitting. Considering the band structures and contribution of reactive species, a direct Z-scheme photo-catalytic mechanism was proposed to rationalize the superior photo-catalytic behavior of LaFeO₃-MoS₂ nano-composite. (Das et al., 2021).

Fu et al. (2022) investigated that a visible light-driven polymeric carbon nitride (PCN)/(Pt)/nano-spherical MoS₂ photo-catalysts was prepared using a self-assembly method. The structure of photo-catalysts was explored by FT-IR, XPS, XRD, BET, SEM and TEM. Meanwhile, the energy band structure and electron hole separation efficiency were also analyzed by UV-Vis and PL spectra. In addition, the photo-catalytic performance of photocatalyst were test by photo-catalytic degradation of Rhodamine B and photo-catalytic hydrogen evolution. The results showed that PCN/ 2.0%MoS₂ showed the best photo-catalytic performance, and the degradation rate of Rhodamine B could reach 98.39% within 150 min. Besides, the introduction of Pt nanoparticles significantly improved the photo-catalytic activity. The degradation rate of Rhodamine B reached 100% within 150 min, and the rate of photo-

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

catalytic hydrogen production of PCN/Pt/MoS₂ system was increased by 21.3% over the PCN/2.0%MoS₂ system. The separation mechanism of electron and hole was Z-scheme mechanism and the main active substances for photocatalytic degradation were ·O₂⁻ and h⁺ (Fu et al., 2022).

Li et al. (2019) investigated that the developed a piezoelectric promoted full solar spectrum photo-catalytic system by assembling full solar response Ag₂O NPs on piezoelectric MoS₂ NFs. The separation of photo-induced electrons and holes could enhance the photo-catalytic properties of photo-catalysts. A piezoelectric field was created inside piezoelectric materials, such as ZnO and MoS₂, by applying strain. The electrons and holes become separated under the driving force of the piezoelectric field. Here, we proposed combining piezoelectric MoS₂ nano-flowers (NFs) and full solar response Ag₂O nanoparticles (NPs) to form a MoS₂@Ag₂O hetero-structure and achieve high efficiency full solar (UV, visible, and near infrared) photo-catalysis. Under both full solar light and ultrasonic excitation, the MoS₂@Ag₂O hetero-structures could rapidly degrade methyl orange (MO) in aqueous solution. A built-in electric field was formed by the spontaneous polarization potential of the MoS₂ NFs during this process an ultrasonic wave as a driving force can consecutively change the potential created by the piezoelectric effect. Under light irradiation, electrons and holes were generated in the Ag₂O NPs, and the photo-generated electrons and holes with opposite signs in the two Ag₂O NPs at the two surfaces of the MoS₂ NFs, could be separated respectively, along the spontaneous polarized direction. Therefore, the piezoelectric effect induced enhancement of carrier separation under ultrasonic excitation can improve the full solar photo-catalytic performance of the MoS₂@Ag₂O hetero-structures. (Li et al., 2019).

Zhao et al. (2013) demonstrated that the co-catalysts for H₂ production were often made from expensive noble metals, such as the most efficient Pt. The alternative non-noble metal co-catalysts with low cost and high efficiency were therefore highly desirable for economically viable H₂ production. They demonstrated that a CdS/MoS₂/Mo sheets system simultaneously containing photo-catalysts, co-catalysts, and conductive supports, was prepared via the one-step hydrothermal process by Mo sheets as template and Mo sources. The obtained CdS/MoS₂/Mo sheets possessed the superior photo-catalytic H₂ production via water splitting under visible light irradiation, which achieved an extraordinary H₂ production of 4540 mol h⁻¹ g⁻¹, up to 28.6 and 3.6 times greater than that of CdS alone and Pt/CdS. The synergetic effect of MoS₂ as co-catalysts and Mo sheets as conductive supports contributed to the dramatically improved photo-catalytic H₂ evolution activity of CdS photo-catalysts, by means of facilitating charge carriers separation and providing active sites for proton reduction. These findings provided a straight forward and practical route to produce cheap and efficient co-catalysts for large-scale water splitting. (Zhao et al., 2013).

Liu et al. (2017) investigated that Molybdenum disulfide (MoS₂) had extensive applications in industries as solid lubricants and catalysts. To improve the lubricating performance of MoS₂, novel double-hollow-sphere MoS₂ (DHSM) nanoparticles with an average diameter of approximately 90 nm were synthesized on sericite mica (SM). The DHSM/SM composite was used as an additive in polyalphaolefin oil, friction and wear decreased by 22.4% and 63.5% respectively. The low friction and wear were attributed to the easy exfoliation of DHSM. The DHSM/SM composite was then rubbed under 40 MPa for 1 h to investigate the exfoliation and functional conversion behaviors of DHSM. Results showed that DHSM (lubricating structure) on SM could be completely exfoliated into nano-sheets (catalytic structure) by rubbing. The

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

nano-sheets exfoliated from DHSM presented good photo-catalytic activity for the removal of organic compounds from waste water. Their work provided both a novel solid lubricant for industrial applications and a possible approach to designing a novel green lubricant for use as a photo-catalyst in organic waste treatment after lubricating service life. (Liu et al., 2017).

Wang et al. (2016) investigated that novel co-catalysts based on few layered MoS_2 and TiO_2 nano-materials had been designed by growing MoS_2 nano-sheets on the surface of TiO_2 nano-spheres through a facile hydrothermal method. The method allowed the formation of $\text{TiO}_2/\text{MoS}_2$ coreshell hetero-structures of uniform morphologies and stable structure and provides a good control over shell thickness. The mechanism that formed these hetero-structures was discussed in detail. In addition, as co-catalyst, MoS_2 nano-sheets could enlarge the light harvesting window to include visible light and improve the photo-catalytic ability of TiO_2 . Using Rhodamine B as the model, the resultant hetero-structure was demonstrating to possess excellent and stable photo-catalytic activity in the degradation of organic pollutants under visible light illumination. The $\text{TiO}_2/\text{MoS}_2$ hetero-structures possessed this catalytic activity due to their large surface area and their excellent interface for separating holes and electrons. Their novel hetero-structure nano-materials possessed potential applications in water treatment, degradation of dye pollutants, and environmental cleaning. (Wang et al., 2016).

Su *et al.* (2020) investigated that a novel few-layer $\text{MoS}_2@\text{TiO}_2$ hollow sphere heterostructures ($\text{MoS}_2@\text{TiO}_2$ HSH) was successfully synthesized by a hydrothermal method which was constructed by few-layer MoS_2 grown on TiO_2 hollow spheres. Systematical characterization revealed that the hollow sphere structure was preserved during the hydrothermal process, while the surface of hollow spheres TiO_2 became roughened after the few-layer MoS_2 grown on TiO_2 . The $\text{MoS}_2@\text{TiO}_2$ HSH showed excellent photo-catalytic ability, assessed by the performance of degrading Rhodamine B (RhB) solution under visible light ($400 \text{ nm} \leq \lambda \leq 800 \text{ nm}$). The photo-degradation rate based on $\text{MoS}_2@\text{TiO}_2$ HSH could be 95% after 120 min, which was more efficient than the pure TiO_2 and MoS_2 . The reason why the composites had such an excellent photo-catalytic performance was the formation of hetero-structures enhanced the ability of separating the photo-generated electrons–holes further reduces the electron–hole recombination rate. Their findings would shed light on the design of flexible photo-catalysis material (Su et al., 2020).

Benavente et al. (2018) investigated that a series of novel hetero-structured hybrid layered ZnO and MoS_2 nano-sheets composites were successfully prepared with different MoS_2 contents. Among all the prepared materials, ZnO/MoS_2 (1:0.05) composite showed enhanced photo-catalytic activity for methylene blue degradation under direct solar light compared with pristine ZnO . The MoS_2 component played a key role for the visible light activity of the composite system at longer wavelengths. The kinetic equations of photo-catalytic reaction and possible photo-catalytic degradation mechanism were investigated. Their results indicated that it belonged to the zero order kinetic and the photo-generated electrons were transferred from hybrid layered ZnO to the MoS_2 nano-sheets, facilitating an interfacial electron transfer suppressing the recombination of charge carriers during the photo-catalytic degradation. (Benavente et al., 2018).

Liu et al. (2018) investigated that the design of highly efficient catalysts had already been a challenge in the exploration of renewable energies based on nanotechnologies. Herein, a feasible strategy of three-dimensional (3D)/two-dimensional (2D) nano-junctions was employed to achieve a prominently enhanced activity in both solar hydrogen evolution and

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

electrochemical hydrogen generation from water splitting. Flower-like MoS₂ nanoparticles with thin-layers were fabricated using a one-pot hydrothermal process and were further attached to g-C₃N₄ nano-sheets via their (002) crystal planes to form an intimate face-to-face contact. The hybrid catalysts exhibited a red-shift to the visible light region with an enhanced absorption capacity. At the optimal loading of 0.5 wt% MoS₂, MoS₂/g-C₃N₄ exhibited the highest photo-catalytic H₂ evolution rate of 867.6 μmol h⁻¹ g⁻¹ under simulated sunlight irradiations, which is 2.8 times as high as that of pure g-C₃N₄. Furthermore, the average photo-catalytic H₂ evolution rate was elevated to ca. 5 times as high as that of pure g-C₃N₄ under visible light irradiations. The synergistic effect responsible for the enhanced HER (hydrogen evolution reaction) performance might be originated from the intimate interface between the light-harvesting g-C₃N₄ and MoS₂ as the active sites with the decreased over potential, lowered charge-transfer resistance and increased electrical conductivity, leading to a more efficient charge separation and a higher MoS₂/g-C₃N₄ lead to the enhancement of electrochemical HER performance compared to pure g-C₃N₄. Their work provided a feasible protocol for rational design of highly efficient HER electro-catalysts and photo-catalysts towards future energy innovation. (Liu et al., 2018).

Wang et al. (2016) investigated that MoS₂ nanodots modified TiO₂ (P25) composite photocatalyst (MoS₂/P25) was fabricated via a facile liquid ultrasonic mixing method. Compared to the pure P25, the MoS₂/P25 exhibited improved photocatalytic degradation activity under simulated sunlight with rhodamine B (RhB) and methyleneblue (MB) as the target pollutants. RhB or MB (40 mL 10 mg/L) completely degraded within 20 min. and the kinetic constant reached 0.221 and 0.253 min⁻¹ for RhB and MB, respectively. Based on the characterization of transient photocurrent response measurement and UV-Vis. diffused reflectance spectra, a possible photocatalytic mechanism was proposed. The enhanced photocatalytic performance was attributed to the heterostructure of P25 and MoS₂ nanodots, improved their charge separation and enhancing their absorption capacity to the full sunlight spectrum. We believed that this study would contribute to the development of new photocatalysts and improving the catalytic performance of traditional photocatalysts. (Wang et al. (2016).

Nazneen et al. (2020) demonstrated that nanoparticles of Ag doped molybdenum disulfide (Ag_xMoS₂) were synthesized by hydrothermal process. The structural, morphological, and optical characteristics of these nanoparticles were characterized by scanning electron microscopy (SEM), Raman spectroscopy, and photoluminescence spectroscopy (PL), respectively. Raman spectra confirmed the formation of MoS₂ and Ag-doped MoS₂ nanoparticles. SEM images indicated that sheet-like structure is prepared in undoped MoS₂, while Ag_xMoS₂ had a particle like structure. PL peaks were observed at 600 nm (2.06 eV), 610 nm (2.03 eV), 700 nm (1.77 eV), 725 nm (1.71 eV), and 730 nm (1.69 eV) for pure, 1% and 2% Ag_xMoS₂. When the doping amount of Ag was increased further (i.e., to 3% Ag-doped MoS₂), new peaks at 636 nm (1.9 eV) and 663 nm (1.87 eV) were observed due to an increase in structural defects. The photocatalytic activity (PCA) of undoped and Ag-MoS₂ was estimated by monitoring the degradation of rhodamine blue (RhB) and methylene blue (MB) dyes. The PCA of Ag_xMoS₂ samples were greater than that of undoped MoS₂ when irradiated with visible light, which was attributed to increased electron-hole pair separation. (Nazneen et al., 2020).

Thomas et al. (2021) reported that the two-dimensional (2D) molybdenum disulfide (MoS₂) based materials were of great interest because of their capacity to efficiently absorb

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

electromagnetic spectrum in the visible region. Starting from the structural and electronic properties, there review discussed the synthesis strategies of 2D MoS₂. The major photocatalytic applications of 2D MoS₂ such as hydrogen evolution, pollutant degradation, self-cleaning, photoelectrochemical water splitting, and microbial disinfection were summarized. The mechanistic understanding of various photocatalytic applications of 2D MoS₂ were summarized through schematic diagrams. In addition, their review showed the methodologies for improving the 2D MoS₂ photocatalysts and recapitulates the research directions in this area of semiconductor photocatalysis. (Thomas et al., 2021).

Raja et al. (2017) investigated that a PbS/MoS₂ nanocomposite was synthesized in different molar ratio of PbS 0.5%, 1.0% and 1.5% by precipitation e deposition method and successfully characterized by various instrumental techniques such as UV-visible diffuse reflectance spectra (DRS), X-ray diffraction (XRD), Scanning electron microscopy (SEM), Energy dispersive X-ray spectrometry (EDX), BET-surface area, photoluminescence (PL) spectroscopy. The photocatalytic activity was monitored via the degradation of methylene blue dye and the results revealed that 1% PbS/MoS₂ better photocatalytic activity than that of 0.5%PbS/MoS₂ and 1.5%PbS/MoS₂. The effect of operational parameters such as pH and catalyst dosage on the photocatalytic activity was investigated. The PbS-MoS₂ nanocomposite exhibit excellent photocatalytic degradation on methylene blue (MB) dye under visible light irradiation. (Raja et al., 2017).

Wang *et al.* (2018) examined that nano-sized materials had attracted tremendous attentions because of their promising practical applications and theoretical values. The nano-sized materials were able to not only enhanced the intrinsic properties of their bulk counterparts but also give birth to new promising properties. Herein, heterojunctions consisted of graphene oxide (GO) and three different MoS₂ nanostructures, including nanoflowers, nanoparticles, and quantum dots, were constructed and used as photocatalysts in water splitting. The electrochemical behavior and photocatalytic performance of MoS₂/GO composites were found closely related to the particle size and morphology of MoS₂. Compared to bulk MoS₂/GO photocatalyst, nano-sized MoS₂/GO heterostructures exhibited obviously enhanced performance in photocatalytic hydrogen generation. Benefitting from the surface effect and the quantum confinement in MoS₂ quantum dots, MoS₂ quantum dots/GO displayed the highest photocatalytic activities. Their study indicated that the decrease in the dimension of MoS₂ could effectively increase the photocatalytic hydrogen evolution performance of MoS₂/GO heterostructures, and thus suggested preferred strategy to design other HER photocatalysts based on MoS₂. (Wang et al., 2018).

Thangavel *et al.* (2017) investigated that the use of two-dimensional nanomaterials as co-catalysts in the photodegradation of toxic compounds using light irradiation were an attractive ecofriendly process. In their study, they prepared a novel MoS₂/Ag₂WO₄ nano hybrid via a one-step hydrothermal approach and the photocatalytic properties were investigated by the degradation of methyl-orange under stimulated irradiation. The nanohybrid exhibits enhanced efficiency in dye degradation compared to the bare Ag₂WO₄ nanorods; the same had been evidently confirmed with UV-visible spectra and total organic carbon removal analysis. The pseudo-first order rate constant of the nano hybrid was nearly 1.8 fold higher than that of the bare Ag₂WO₄ nanorods. With the aid of classical radical quenching and photoluminescence spectral analysis, a reasonable mechanism had been derived for the addition of MoS₂ to nano hybrids to enhance the photocatalytic efficiency. MoS₂ prevented photo corrosion of Ag₂WO₄

and also diminished the number of photogenerated electron-hole recombination. Their findings could provide new insights in understanding the mechanism of the MoS₂/Ag₂WO₄ nanohybrid as an efficient photocatalyst suitable for waste-water treatment and remedial applications. (Thangavel et al., 2017).

3. METHODS and MATERIAL

Experimental procedure

For the preparation of MoS₂ nanoparticles, the chemicals are purchased in analytical grade (AR) with 98% purity. In the slow evaporation process, 2.4712 g of ammonium heptamolybdate and 0.15224 g of thiourea were taken as sources for Mo and S. The source materials are dissolved in 50 ml of distilled water under magnetic stirring, and kept at 60 °C for 24 h. The measured pH value of the solution was six. The precursor solution was allowed to evaporate slowly under ambient condition, and the resultant products were exploited. Then it was washed with the distilled water–ethanol mixture and centrifuged. After that, the colloidal suspension was dried at room temperature and in normal air atmosphere. The final products of fine nanoparticles were obtained. A schematic of the experimental process is shown in Fig. 1 (Lalithambika, et al., 2019).

Figure 1. Experimental process of MoS₂ nanoparticle preparation

Characterization

The prepared particles were characterized using X-ray diffractometer (XRD) for crystal structure analysis, morphological analysis using scanning electron microscope (SEM), elemental analysis using energy-dispersive X-ray analysis (EDAX) system, functional group analysis using Fourier infra-red spectrophotometer (FTIR), and vibrational and rotational analyses of the prepared particles are characterized by Raman spectroscopy.

Evaluation of dye degradation

The dye degradation efficiency of the prepared nanoparticles is tested against two industrial standard dyes MB and MG under the illumination of a Xe arc lamp of power 300 W. A required amount of prepared nanoparticles were dissolved in 100 ml of aqueous solutions of MB and MG separately and stirred in the dark atmosphere until the equilibrium is reached. Under the

visible light irradiation, the dye and sample mixtures were exposed for every 15 min. The photocatalytic reaction was monitored and recorded by taking the absorption spectrum for MB ($\lambda=664$ nm) and MG ($\lambda=617$ nm) using a UV–visible spectrometer (Systronics, 2003).

Computational details

Density functional theory implemented in ATK-VNL [26] package is employed to validate the photocatalytic performance of MoS₂ nanoparticles. A supercell of MoS₂ consisting of 32 atoms is constructed and optimized. The exchange–correlation interaction was estimated by generalized gradient approximation (GGA) with Perdew–Burke–Ernzerhof parameterization. A 4×4×4 Monkhorst–Pack k-point grid was used to treat the supercell. Cutoff energy of 400 eV Å⁻¹ and total energy tolerance of 105 eV were used for the total energy calculation. The effective mass calculation is done along (1 0 1) direction of the optimized supercell.

4. RESULTS and DISCUSSIONS

4.1. Structural and morphological properties

The phase composition and the crystalline structure of the prepared sample are analyzed by X-ray diffractograms between 10° and 80° (Fig. 2). The XRD patterns show that the sample is mainly composed of MoS₂ and a small amount of Mo₂S₂. The diffraction peaks (2 θ) positioned at 14.39°, 29.02°, 32.68°, 35.88°, and 39.55° are assigned to the lattice planes (002) (004) (100) (102) (103), respectively, of crystalline MoS₂ (JCPDS card no. 65-0160). However, the peaks at 13.76°, 19.23°, 30.73°, and 31.48° are attributed to the lattice planes (101) (110) (121) (113) of Mo₂S₂ (JCPDS card no. 82-1709). The crystalline size of the prepared MoS₂ nanoparticles is calculated using Scherrer's formula.

$$D = \frac{K\lambda}{\beta \times \cos \theta}$$

Table 1 shows the calculated crystalline and lattice parameters of the prepared MoS₂ nanoparticles.

Figure 2. XRD pattern of prepared MoS₂ nanoparticles

Table 1 Lattice parameters of MoS₂ nanoparticles.

Sample	D(nm)	a (Å)	c (Å)	c/a
MoS ₂	56	3.1667	12.421	0.2549

The morphological and elemental analyses of the prepared MoS₂ nanoparticles are shown in Figs. 3 and 4. From the SEM analysis, it is seen that the grown particles are spherical in nature with high porosity. The porosity among the clustered nanoparticles helps to degrade of organic dyes effectively. Figure 4 confirms the presence of Mo and S elements in the prepared sample.[14]

4.2 FTIR spectrum analysis

Figure 5 shows the FTIR spectrum of the prepared MoS₂ nanoparticles. There are broad absorption bands at 639 cm⁻¹, 893.39 cm⁻¹, 1402.99 cm⁻¹, and 1622.8 cm⁻¹, which are attributed to MoS₂. The band at 483.23 cm⁻¹ is due to the S–S bond and that at 931.39 cm⁻¹ is due to the S–S bond. The peaks at about 3182 cm⁻¹ belong to the characteristic bands of the O–H group.

4.3 Raman spectra analysis

The Raman spectrum (Fig. 6) of bulk MoS₂ has two prominent peaks and they are ascribed as in-plane (E_{2g}) mode located around 381 cm⁻¹ and an out-of-plane (A_{1g}) mode which is located at 397 cm⁻¹. The out-of-plane mode is due to the sulfur atoms vibrating out-of-plane, and the in-plane mode is a mixed atom vibrations of Mo and S on the opposite directions.

Another peak observed at 391 cm^{-1} may be due to the presence of Mo_3S_4 phase discussed in the XRD.

Figure 3. SEM images of MoS_2 nanoparticles

4.4 Photocatalytic studies

The dye degradation efficiency of the prepared nanoparticles has been investigated against MB and MG under the illumination of visible light. The photocatalytic dye degradation can be ascribed based on the absorption of light by the dye molecules present in the sample and also used to understand the catalytic activity of the MoS_2 nanoparticles. Figure 7 shows the absorption spectra of MB and MG dyes under the visible light irradiation at different times. It is clear from the figure that the absorbance of the dye molecule decreased (maximum peak at $\lambda=664\text{ nm}$ for MB and $\lambda=617\text{ nm}$) when the exposure time is increased. Since the concentration of the dye molecules is directly proportional to the absorption, the photocatalytic efficiency of the prepared MoS_2 nanoparticles can be calculated using the formula.

$$\eta = \frac{C_0 - C}{C_0} \times 100\% = \frac{A_0 - A}{A_0} \times 100\%$$

Where C_0 and C are the initial and reaction time concentration of the used dyes. A_0 and A are the absorption values measured using UV-visible spectrometer.

Fig. 4 EDAX spectrum of nanoparticles

Figure 8a shows the variation of C/C_0 over MoS_2 light irradiation time. It is clear from the figure that the prepared MoS_2 nanoparticles are more efficient for MB compared to MG. The degradation of dyes under light irradiation is treated as pseudo first-order kinetic reaction and this exhibits a linear variation between and irradiation time. Figure 8b shows that a near linear relationship between the kinetic data of the degradation of dyes, which can be fitted with Langmuir–Hinshelwood first-order reaction kinetic model. In addition, the reaction rate constant for MB and MG dye degradation is calculated using the following formula

$$\ln\left(\frac{C_0}{C_t}\right) = kt,$$

Where “k” is the rate constant. The calculated efficiency values (Table 2) indicate that MoS_2 can be effectively degrade both dyes. However, comparing to MG degradation efficiency, MoS_2 is more reactive on MB. This may be due to enhanced binding effect and charge transfer between the MoS_2 and MB dye molecules. Generally, the photocatalytic materials provide more active sites on their surfaces and strong absorption against the organic dye molecules. In particular, the layered materials provide easy transfer of photogenerated charges, which determines the photocatalytic characteristics of the material against the degradation of organic dye molecules. Since, the prepared MoS_2 nanoparticles possess layered nature, it provides high charge transfer for the photogenerated charge carriers along its surface and thus exhibit high efficiency of dye degradation. As compared to gC_3N_4 and TiO_2 nanoparticles prepared for photocatalytic dye degradation, MoS_2 is best suited for this purpose. The reason for this is it has a bandgap range lie in the range of visible light. However, TiO_2 has the bandgap in UV range and gC_3N_4 is exhibiting semi-metallic nature. This enables MoS_2 as a suitable candidate for visible-light photocatalytic material. Moreover, the general mechanism of MoS_2 to degrade organic dyes is follows.

Table 2 Degradation rate constant and efficiency of MoS₂ nanoparticles

Sample	Rate constant (k) (min ⁻¹)		Efficiency (η %)	
	MB	MG	MB	MG
MoS ₂	0.0199	0.01389	93.68	85.33

i) Absorption of light by MoS₂ nanoparticles generates electron and holes due to its low bandgap.

ii) The photogenerated electrons in the conduction band react with oxygen molecules present in the solution and form superoxide radicals (O₂⁻). These superoxide radicals react with H⁺ ions and form H₂O₂. Further, the H₂O₂ decomposes into hydroxyl radicals (•OH).

iii) Consequently, the photo-separated holes in the valance band react with water molecules and produces hydroxyl radicals (•OH).

TeMALab

September 14-15, 2023, Naples, Italy

iv) Finally, these hydroxyl radicals react with the dye molecules (MB and MG) and decompose into CO₂ and H₂O.

Density functional theory analysis

The degradation efficiency of the prepared MoS₂ nanoparticles can be explained theoretically by the following factors: (i) bandgap, (ii) effective mass and, (iii) band edge potentials. In this present work, using DFT, the above factors are measured. The optimized structure of MoS₂ nanostructure is shown in Fig. 9a. The calculated bond length between Mo and S atoms is 2.416 Å, and Mo–Mo is 3.19 Å, which are almost close to the previously reported values of 2.14 Å and 3.16 Å, respectively.

From the band structure (Fig. 9b), it is seen that the material possesses indirect bandgap (G–K) of 1.4 eV, which is well within the visible region. This is one of the required properties for visible-light-driven photocatalysis materials. The calculated projected density of states (PDOS) spectrum (in Fig. 9c) reveals the contribution of orbitals of ‘Mo’ and ‘S’ atoms over valance and conduction bands of the MoS₂ nanostructure. It is clear from the figure that the influence of the number of DOS is majorly dominated by Mo ‘4d’ and S ‘3p’ orbitals and this enables the charge transfer across the structure. However, the influence of other valance orbitals of Mo and S atoms are in-significant. For the evaluation of the photocatalytic activity, band edge potentials play an import role in the redox process. The band edge potentials play a vital role for oxidation and reduction capabilities of MoS₂ against organic pollutants. The band edge potentials of MoS₂ are calculated using the following relations

$$E_{vb} = \chi - E_e + 0.5 \times E_g$$

$$E_{cb} = E_{vb} - E_g$$

Where χ is electronegativity, E_e is the free electron energy in hydrogen scale, and E_g is the calculated bandgap. For MoS₂ the calculated band edge potentials are –0.39 V and 1.31 V for the conduction and valance bands, respectively. For an efficient photocatalytic material, it should meet the following conditions.

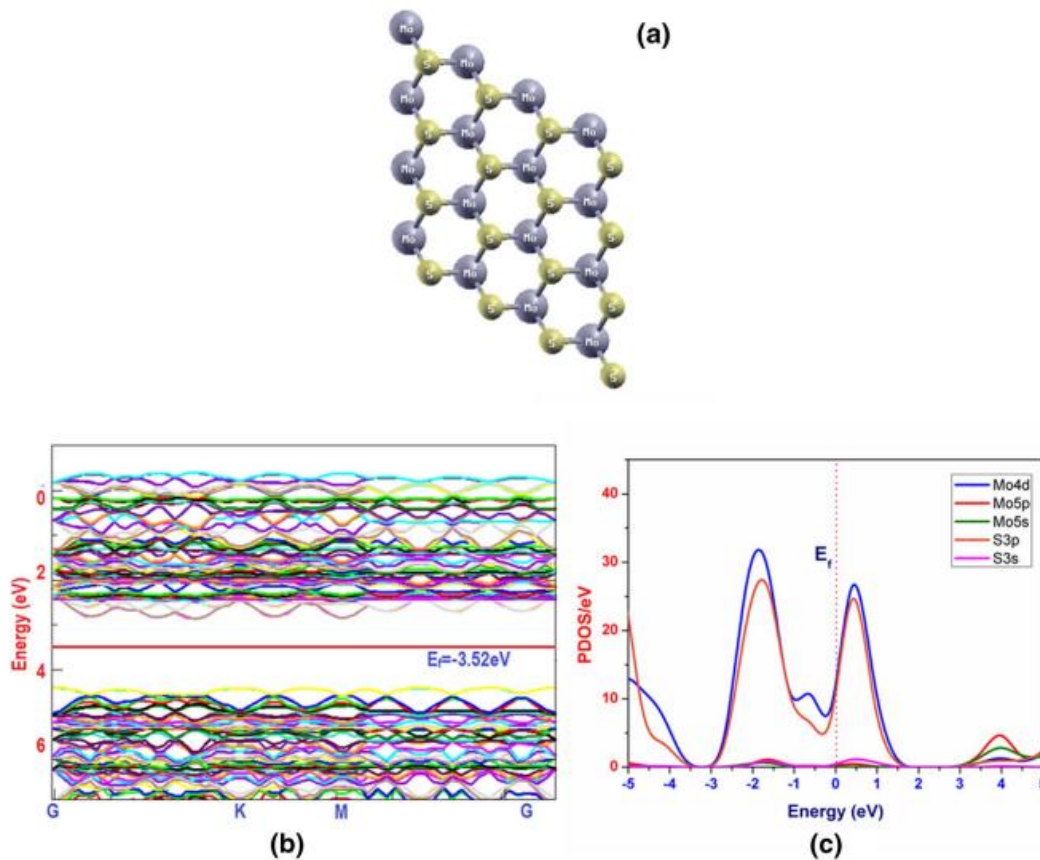

Fig. 9 (a) Optimized structure, (b) bandstructure and (c) PDOS diagrams of computed MoS₂ nanostructure

- i) Conduction band potential should > 1.23 V
- ii) Valance band potential should > 1.23 V

In this present study, the calculated band edge potentials are well satisfied with the above criteria, and hence a suitable candidate for visible-light-driven photocatalysis for organic pollutant degradation. Another important parameter to qualify a photocatalysis material is effective mass (m^*). For an efficient photocatalytic reaction, the mobility of the conduction band electrons should be minimum, and hence it reduces the recombination rate. Due to this, the free electrons in the valance band reach the reaction sites effectively. The effective mass, however, is directly related to the mobility of the charge carriers using the following equation

$$\mu = e \frac{\tau}{m^*},$$

Where m^* is the effective mass of the charge carriers, τ is the collision time, e is a charge of the electron and μ is the mobility. It is seen from the above relation that higher effective mass of the charge carriers results in lower mobility and hence lower recombination. The calculated effective mass of MoS₂ nanostructure is $0.42 m_e$. Based on a report by Bahers, for a best photocatalytic material, the effective mass of the charge carriers in one crystal direction should be less than $0.5 m_e$. In this present work, the calculated effective mass is $0.42 m_e$, which reduces the diffusion coefficient hence reduces the recombination. In overall, the DFT analysis results

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

September 14-15, 2023, Naples, Italy

indicate the MoS₂ nanostructures are one of the potential candidates for photocatalytic organic pollutant degradation. (Lalithambika, et al., 2019).

5. FUTURE RECOMMENDATIONS

5.1 Conclusion

MoS₂ nanoparticles have been prepared by a simple and inexpensive method for photocatalytic dye degradation of MB and MG dyes. The XRD of the prepared nanoparticles showed the mixed phases of MoS₂ and Mo₃S₄. The EDX spectrum confirms the presence of Mo and S elements. The Raman spectrum of prepared MoS₂ nanoparticles have two prominent peaks at 383 cm⁻¹, 407 cm⁻¹ corresponds to in-plane (E_{2g}) mode and an out-of-plane (A_{1g}) mode, respectively. The photocatalytic test was performed for the prepared samples against MB, and MG dye and the efficiencies are calculated as 93.68% and 85.33%, respectively. A DFT-based calculation is performed to validate the experimental results and also to get an insight into the photocatalytic mechanism, based on bandgap, band edge potentials, and effective mass. (Lalithambika, et al., 2019).

5.2 Future Recommendations

Tailoring the nanostructure : Further research should focus on fine-tuning the nanostructure of MoS₂ materials to enhance their photocatalytic performance. This includes controlling the size, shape, and morphology of the nanomaterials. By optimizing these parameters, it is possible to enhance light absorption, charge carrier generation, and surface reaction kinetics, leading to improved overall efficiency.

Surface modification and functionalization: Surface engineering plays a crucial role in improving the photocatalytic properties of MoS₂ nanomaterials. Future studies should explore surface modification techniques, such as chemical functionalization or deposition of co-catalysts, to enhance charge separation, promote specific reactions, and increase stability. Functionalization can also help in mitigating issues such as photo corrosion and recombination of charge carriers.

Co-catalyst integration and heterostructure design: The integration of MoS₂ nanomaterials with appropriate co-catalysts or the formation of heterostructures can significantly enhance their photocatalytic activity. Future research should focus on identifying suitable co-catalysts and exploring their synergistic effects with MoS₂. Additionally, the design of heterostructures involving MoS₂ with other semiconductors can enable efficient charge transfer and broaden the absorption range, leading to enhanced photocatalytic performance.

Mechanistic understanding: To maximize the potential of MoS₂ nanomaterials in photocatalysis, it is crucial to deepen the understanding of the underlying mechanisms. Future research should employ advanced characterization techniques, such as in situ spectroscopy and ultrafast spectroscopy, to unravel the charge carrier dynamics, reaction pathways, and active sites. This knowledge will aid in the rational design and optimization of MoS₂-based photocatalysts.

Scale-up synthesis and cost-effectiveness: Large-scale synthesis methods that are reproducible, scalable, and cost-effective are essential for practical applications of MoS₂ nanomaterials in photocatalysis. Future research should focus on developing scalable synthesis techniques, such

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

as hydrothermal or solvothermal methods, to produce high-quality MoS₂ nanomaterials in large quantities. This will facilitate their commercialization and widespread implementation.

Environmental impact assessment: As with any nanomaterial, it is crucial to evaluate the potential environmental impact of MoS₂ nanoparticles. Future studies should investigate the fate, toxicity, and long-term effects of MoS₂ nanomaterials in the environment. This will aid in the development of safe and sustainable photocatalytic systems.

In conclusion, future research on MoS₂ nanomaterials for photocatalysis should prioritize tailoring the nanostructure, surface modification, co-catalyst integration, mechanistic understanding, scalable synthesis, and environmental impact assessment. Addressing these aspects will accelerate the development of efficient and practical MoS₂-based photocatalytic systems for various energy and environmental applications.

5.3 Summary

MoS₂ (Molybdenum Disulfide) nanomaterials have emerged as promising candidates for photocatalysis due to their unique properties and potential applications in various environmental and energy-related processes. Here is a summary of MoS₂ nanomaterials for photocatalysis:

Structure and properties: MoS₂ nanomaterials possess a layered structure consisting of molybdenum atoms sandwiched between layers of sulfur atoms. This structure imparts excellent catalytic properties to MoS₂. Nanoscale dimensions introduce a high surface-to-volume ratio, which enhances their reactivity. MoS₂ nanomaterials exhibit a direct bandgap, enabling efficient light absorption, and they can respond to visible light, which is abundant in the solar spectrum.

Photocatalytic activity: MoS₂ nanomaterials exhibit significant photocatalytic activity in various reactions. When exposed to light, they generate charge carriers (electrons and holes) due to their suitable bandgap. These charge carriers participate in redox reactions, such as water splitting, pollutant degradation, and CO₂ reduction. Thus, MoS₂ nanomaterials serve as effective catalysts for clean energy generation and environmental remediation.

Co-catalyst and heterostructure integration: To enhance their photocatalytic performance, MoS₂ nanomaterials can be combined with other materials, such as noble metals (e.g., Pt, Au) or semiconductor nanomaterials (e.g., TiO₂, ZnO). This integration as co-catalysts or heterostructures promotes charge separation, facilitates surface reaction kinetics, and expands the absorption range, resulting in improved photocatalytic efficiency.

Mechanisms and applications: The photocatalytic mechanisms of MoS₂ nanomaterials involve light absorption, charge separation, surface reaction, and charge transfer processes. Their versatile photocatalytic activity enables applications in various fields. These include water splitting for hydrogen production, degradation of organic pollutants, carbon dioxide reduction to value-added chemicals, and solar energy conversion.

Challenges and prospects: Despite the significant progress in utilizing MoS₂ nanomaterials for photocatalysis, there are challenges that need to be addressed. These include improving quantum efficiency, enhancing stability, and developing scalable synthesis methods. Future research can focus on novel synthetic approaches, surface modification techniques, and the exploration of MoS₂-based composites to optimize photocatalytic performance.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

In summary, MoS₂ nanomaterials offer great potential as photocatalysts due to their unique structure, visible light response, and versatile photocatalytic activity. By further advancing their synthesis techniques, integration with other materials, and understanding the underlying mechanisms, MoS₂ nanomaterials can contribute to the development of efficient and sustainable photocatalytic systems for various energy and environmental applications.

ABSTRACT

Coal based thermal power plants have been a key source of power generation in India. The prime waste product of a coal thermal power plants are y ash and bottom ash. Heavy dumping of these waste products causes fatal environment pollution to air, water, and land. This research work is done to deliver the optimum use of ash namely coal ash as a mineral filler, with natural Fiber used to improvise the engineering properties of bituminous paving mixes. To strengthen the mix, slow setting emulsion coated fiber is added in varying percentage by weight of mix, with different length variations. Marshall Stability test is performed to study the Marshall characteristics and determine optimum fiber content including the optimum length of fiber.

Keywords: Bitumen, Coal ash, Fly ash, Fiber, Marshall Stability Test.

1. INTRODUCTION

1.1 Background of the Study

Pavements or highways or roads are regarded as countries backbone, upon which its upswing and progress depend on. All countries normally have a series of programs for building a new road infrastructure or emerging the existing one. Construction of both flexible and rigid pavement include a gross amount of investment to reach better performance oriented and smooth quality of pavement that will endure for long time. In India, where highways are considered as the primary function of transportation, Government of India have been investing a huge amount of money for developing the pavement construction and maintenance. A detailed engineering study may retain significant amount of investment and pavement materials, which in turn achieve a reliable performance of the in-service highway. Regarding flexible pavement, two major facts are taken into considerations i.e., pavement design and mix design. The present research study is focused on engineering property of bituminous mixes prepared from alternate or nonconventional materials.

1.2 Bituminous Mix Design

Bituminous pavement comprises of a mixture of stone chips, graded from nominal maximum aggregates size (NMAS), through the fine fraction smaller than 0.075 mm mixed with appropriate amount of bitumen that can be compacted adequately with smaller air voids and will have adequate dissipative and elastic properties. The aim of bituminous mix design is to determine the fair proportion of bitumen and aggregates fraction to yield a mixture that is effective, durable, reliable, and economical.

1.3 Types of Bituminous Mix

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Bituminous mixes are combination of mineral aggregate and binder that are mixed with their optimum value to lay down and compacted in layers for building smooth road. Mixing of bitumen and mineral aggregates are done in several ways.

1.4 Hot Mix Asphalt

Commonly known as HMA, is prepared by heating bitumen binder and moisture dry aggregate to a mixing temperature of 150 °C to 160 °C (300 °F to 330 °F) which will provide a consistent mixture to work with. Due to high temperature of the mixture it is possible to compact the mixture to its optimum air content to give better stability than others. There as on being which HMA is widely used on highly trafficked roadways such as highways, airfields, and racetracks.

1.5 Warm Mix Asphalt

Frequently known as WMA, is prepared by mixing aggregate and binder at a moderate temperature of 100 °C to 135 °C. The virgin binder is modified with foreign additives prior to mix, which will help bitumen binder to mix properly with mineral aggregate. Due to low temperature of mixing, consumption of fuel and emission of harmful gases are comparatively lower than hot mix. Not only had it improved workability, but also the low-temperature laying helps in accessing road surface much quickly.

1.6 Cold Mix Asphalt

This technique is practiced where high mixing temperature is a problem. The aggregate is blended with an emulsified bitumen (a combination of water and bitumen in a proper ratio) to a mixture that is easy to work and compact. When water evaporates from emulsion leaving back bitumen, the cold mix will, ideally, take on the properties of cold HMA. Cold mix is frequently used as a patch material on a lesser trafficked road.

1.7 Cutback Asphalt

A lighter fraction of petroleum is dissolved with bitumen binder to produce a less viscous liquid that will dissolve with the aggregate and evaporate after compaction is done. Cutback bitumen has been widely used in contradiction due to its nonpolluting characteristic and easy to work with.

1.8 Mastic Asphalt

Mastic asphalt is made by heating hard grade blown bitumen (oxidation) in a green cooker (mixer) until it has turned to a viscous liquid before it is added to aggregates. The mixture is cooked for 6- 8 hours to mature and once the mixer is ready, it is transported to the site where it generally laid in different thickness for footpath, road and for flooring or roof applications.

1.9 Hot mix Asphalt

Hot Mix Asphalt (HMA) is mixture of aggregate and bitumen that are mixed, placed and compacted at higher temperature. The three types of HMA are Dense Graded Bituminous Macadam (DBM), Stone Matrix Asphalt (SMA) and Open graded mix.

2.0 Dense Graded Bituminous Macadam (DBM)

This type of bituminous mix is a well-graded HMA with proper proportion of all aggregate fraction. It is hard and relatively impermeable. Dense-graded mixes are classified as fine-graded and coarse graded.

2.1 Stone Matrix Asphalt

Stone matrix asphalt (SMA), which is occasionally called as Stone Mastic Asphalt, is a gap graded mix, eventually developed to maximize the rutting resistance caused by heavy traffic. SMA has a high coarse aggregate fraction that interlocks to each other, to form a stone

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

skeleton that resists permanent deformation. SMA is preferably used for surface courses on high volumeroads. Mineral filler sand additives are used to check the drain-down of bitumen binder during construction.

2.2 Open Graded Mixes

Unlike DBM and SMA, an open-graded mix is made-up of only stone chip sand bituminous binder. Due to absence of Fine aggregate and filler it became porous and offers surface water to drain down quickly. It is used as a drainage layer under dense-graded HMA, SMA or PCC. It has enough friction with relatively little strength than other. It is purposefully constructed with high air void that reduce road tire noise by up to 50%.

2. OBJECTIVES of THE RESEARCH

This experimental study has done to enable the most appropriate use of coal ash as nonconventional aggregate along with natural fiber (Sisal fiber) as an additive by ensuring the adequate performance result in the field of fatigue, moisture susceptibility, and creep value. Again the possible effects of fiber on bitumen mixes are also taken into consideration, and comprehensive study was done to find the optimum fiber content and fiber length that will increase the engineering property of bituminous mix.

3. SCOPE OF THE STUDY

- The significant scope of this study is to use coal ash as a fine material in HMA mix design and thus producing a good quality and smooth surface road which may be commercially acclaimed and can with stand in any possible environment condition.
- The significant scope of this study is to use coal ash as a fine material in HMA mix design and thus producing a good quality and smooth surface road which may be commercially acclaimed and can with stand in any possible environment condition.

4. RAW MATERIALS USED IN THIS STUDY

In this study following materials are taken in to consideration to prepare the bituminous mix.

- Stone chips (as coarse aggregate)
- Fly ash (as mineral filler)
- VG-30 (as bitumen binder)
- Sisal fiber (as additives)
- SS-1 emulsion (as fiber coating agent)

5. ANALYSIS

5.1 Effect of Sisal Fiber and Coal Ash on DBM mix

Figure 1. Variation of Stability value with bitumen content in 0.5% fiber content at different fiber length

Figure 2: Variation of Stability value with bitumen content in 1% fiber content at different fiber length

Figure 3. Variation of flow value with bitumen content in 0.5% fiber content at different fiber length

Flow value vs Bitumen content

Figure 4. Variation of flow value with bitumen content in 1% fiber content at different fiberlength

Figure 5. Variation of Air Voids value with bitumen content in 0.5% fiber content at

Air void vs Bitumen content

different fiber length

Air void vs Bitumen content

Figure 6. Variation of Air Voids value with bitumen content in 1% fiber content at different fiber length

Figure 7. Variation of VFB value with bitumen content in 0.5% fiber content at different fiber length

Figure 8: Variation of VFB value with bitumen content in 1% fiber content at different fiber length

6. CONCLUSIONS

- From the results of the Marshall tests it is observed that with increase in bitumen content and fiber content (both in weight and length of fiber), the stability values increase up to a certain limit and then decrease (after 6% of bitumen it decreases).
- From optimum binder content analysis, it is found that maximum stability is 13.57KN for 6% bitumen with 0.5% fiber and 10mm fiber length which is coated with SS1 emulsion.
- It is observed that maximum stability value is 13.57KN and corresponding flow value is 4.3.
- With addition of fiber, flow value decreases. With respect to bitumen content, as bitumen % increases, flow value increases when fiber is added.

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

- Due to the addition of fibers increase in fiber content and length of fiber, the air voids (%) decreases.
- With increase in fiber content and fiber length, VFB increases.

ABSTRACT

This article includes several trends of Malaria in recent years. Article highlights controlling disease in urban areas can be achieved in an effective and eco-friendly way by employing biological weapons against mosquitoes. This proactive approach to urban city design promotes a healthy and safe environment for all residents, making it a smart choice. Malaria is one of the most severe diseases and has significantly impacted humans for a long time. Scientists and researchers spend decades finding treatments to cure Malaria. Fortunately, the overall trends are going in positive ways. In the year 1960, people discovered Malaria Vaccines. Literature review methods were used to research current trends. Nowadays, the development of treatment is far beyond Malaria Vaccines since researchers invented Malaria chip-disease model. In addition, the community is enhancing the prevention of Malaria for pregnant women. Before, places like Brazil, India, and Africa didn't have complete systematic prevention of Malaria, which caused a high death rate. However, as more advanced developments appear and more patrons support these poor places, Malaria cases decrease significantly. People all around the world put lots of effort into eradicating Malaria.

Keywords: Biological Warfare, Mosquito-Borne Diseases, Urban Areas.

1. INTRODUCTION

Malaria is one of the deadliest diseases caused by Plasmodium, an animal parasite. Plasmodium lives in an animal's body, then spreads to humans through Anopheles mosquitoes. Once the Anopheles mosquito attaches to the human body, the sporozoites will pass to liver cells, then they start duplicating in the cells, and Merozoites will be released. After that, they will become trophozoites and, eventually, schizonts. Schizonts repeatedly reproduce in the human body. Four types of Malaria parasites are *P. vivax*, *P. ovale*, *P. malariae*, and *P. falciparum*. Although it has been a long time since Malaria appeared, the total death caused by Malaria in 2021 is 61900. Seventy-seven percent of deaths are children, and every minute five children die due to Malaria. In 1880, a French doctor called Alphonse Laveran found Plasmodium in a Malaria patient's blood.

2. IMPACT AND CAUSES OF MALARIA

2.1 Why mosquitoes bite people: In human blood, there's a special protein that female mosquitos need to spawn. Second, carbon dioxide attracts mosquitoes. When people are breathing, mosquitoes find them. Third, they like the smell of a mixture of bacteria and sweat, and that's why mosquitos like people's ankles and feet. Unfortunately, pregnant women are more attractive than more people to mosquitos since pregnant women exhale 21% more air than

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

non-pregnant women and their body temperature is higher. Researchers also find that blood type AB and O are more attractive to mosquitoes than other blood types. Children are more vulnerable to Malaria because they haven't developed complete immune systems to defend against Plasmodium.

2.2 Symptoms: After people are infected by Malaria, they may have headaches, fever, and shivering after a few days. But these symptoms are not for every patient because some people have asymptomatic infections. Asymptomatic infection is very dangerous because if patients don't get cured after 24 hours, they will get worse. Children have more symptoms than normal adults if they are infected with Malaria. Children will have gastroenteritis, encephalitis, or pneumonia followed by fever. What happened in patients' bodies when they are having fever? When they are having fever, erythrocyte schizonts release merozoites. *P. falciparum* is one of the four types of Malaria parasites, and it is the most dangerous one since it causes more complications. For children, the most common complications are CM and SMA. The symptoms of CM are coma, epilepsy, or even loss of awareness. Despite some children can be awake after 24 hours, but still, 10% of them will retain neurological sequelae, such as epilepsy.

2.3 Spreading: Malaria cannot infect from human to human, and it mainly spreads by Anopheles mosquitoes. There are 400 types of Anopheles mosquitoes, and 10% of them can spread Malaria. Also, the spreading depends on different areas and the types of mosquitoes. For example, tropical countries have a higher rate of Malaria infection since high temperature and moist air cause mosquitoes easier to reproduce. Some people are easier infected by Malaria than others like children under 5 and people have poor communities. Not all patients are infected by mosquitoes, some of them have congenital malaria, and *Plasmodium vivax* is the most common congenital parasite.

Ring Stage				
Trophozoite				
Schizont				
Gametocyte				

Figure 1. This picture shows 4 stages of Malaria parasite, and 4 types of Malaria parasites.

3. TREATMENTS OF MALARIA

Besides Malaria vaccines, there is a complete system of diagnosis of Malaria, such as blood testing, that shows which type of Malaria the patient gets, etc. Via blood tests, doctors can

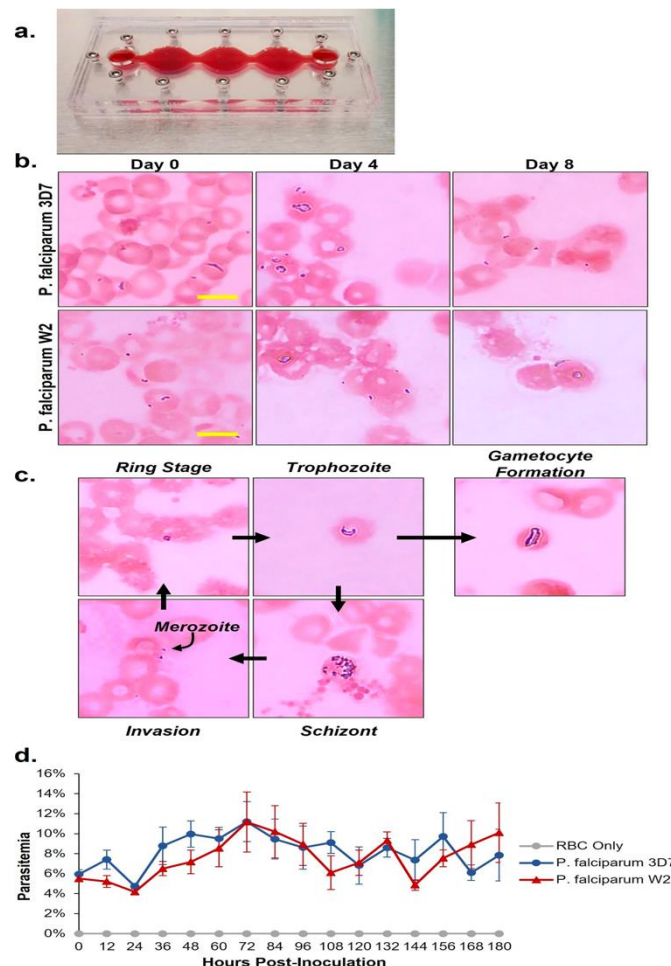

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

regulate drugs depending on the characteristics of the patients, like age and symptoms. The common medicines are Chloroquine, Quinine sulfate, Hydroxychloroquine, and Mefloquine.

3.1 High Technology of Treatment: Researchers have invented a multi-function, multi-organ, serum-free system used to culture *P. falciparum*. This system simulates four human organs (liver cells, spleen, endothelial cells, and recirculating red blood cells). This malaria-on-a-chip disease model tests the efficiency of various drugs and off-target toxicity. Researchers must check the cells' viability and morphology for seven days to achieve the target. For the experiment, scientists added two strains of *P. falciparum*, the 3D7 strain, and the W2 strain; one is chloroquine-sensitive, and one is chloroquine-resistant. This result shows the 3D7 strain palindromic at day five, whereas the W2 strain reduces its level after injecting chloroquine. The experiment testifies the chip model's functions are practical since it can test both drug's effectiveness and the responses of immune organs on *P. falciparum*.

(a) is the Malaria chip-disease model, the 3 red dots are representing the simulators of liver cells, spleen cells, and endothelial cells. (b) The conditions of both *P. falciparum* W2 and *P. falciparum* 3D7 on day 0, day 4, and day 8. Clearly, the parasites decrease every 4 days, which means chloroquine is effective to cure *P. falciparum*. (c) indicates the cycle of Malaria's stages, and it includes a special staging which is gametocyte formation. Gametocytes are formed in blood cells and usually in a shape like a sausage.

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

3.2 Particular Areas: According to the 2021 World Malaria Report research, 87 countries still have Malaria risk. Places in Brazil, Africa, and India still have severe problems due to Malaria. However, in recent years, the number of deaths from Malaria has decreased significantly. The Pan America Health Organization supports treatment in America. For example, Brazil reduces Malaria deaths by 61% down and hospitalization down 84%. In addition, Honduras's Health Surveillance expands diagnostic coverage and treatment. Paraguay's National Program creates a strategy of "3T" (Testing, Treating, and Tracking). Based on the "Malaria Champions of America, Brazil, and Haiti put effort into reducing Malaria cases. From 2013 to Oct 2017, Malaria cases decreased from 8000 to 126. Not only do PAHO and HHSU work on preventing Malaria, but some investments also support defeating Malaria, for instance, Bill and Melinda Gates Foundation's strategy and "Malaria Zero" in America. Gates Foundation has donated 258.3 million dollars for Malaria vaccines and drugs, and they also have granted money for buying Mosquito nets and then sent them to poor areas.

In China, there are 60 types of Anopheles mosquitoes. Plasmodium sinensis is a special type of Malaria parasite that only appeared in China, but it's not very effective in spreading. Plasmodium sinensis is common in mountains. Another type of parasite in China is An. Anthropophagus and it emerges in Yunnan, Guizhou, and Liaoning. Researchers found An.dirus in Hainan province since 2010. China Health Organization recommends using ITNs and LLIN to prevent Malaria. During the period 1960-1979, Malaria cases increased quickly in China, and An. Minimus is the primary vector. China did have a strategy for prevention, for instance in 1983, China started to train and test. IRS and LLINs support the prevention of Malaria. Luckily, from 2000-2009, Malaria cases were reduced. To eliminate Malaria, 13 ministries and commissions established the "China Malaria Elimination Action Plan" which accelerated the elimination of Malaria cases in China. Since 2010, mosquito nets have become the most important tools for preventing Malaria. In 2020, the National Health Commission published "Administrative Measures for Preventing Re-establishment of Transmission by Imported Malaria". During the process of reducing Malaria in China, Tu Youyou, a great pharmacologist found artemisinin in 1972. In the 1960s, chloroquine was ineffective against Malaria, and lots of people dies from Malaria. She led her team to extract the antimalarial components in artemisinin by using a low boiling point solvent. Artemisinin saved a million lives in China.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

The image shows the trends of Malaria cases in different regions, the total number of cases was increasing till 2005, then it started to decrease after 2015. After that, there was an increasing trend from 2016 to 2019, but it is not serious as in 2005.

3.3 Pregnancy treatment: It is pretty dangerous for pregnant women having Malaria, especially *P. falciparum*. Malaria may harm the baby through the placenta; for example, it will cause women anemia. Today, it is very difficult to discriminate whether a person has congenital malaria or is infected by mosquitoes. In Africa, more than 13 million pregnancies were exposed to Malaria infection. To help pregnant women prevent Malaria, CHWs will send every pregnant woman the sulfoxide-pyrimethamine, a medicine that helps to prevent Malaria. 2012 WHO guidance asserted that each pregnant woman must receive three doses of preventive treatment (IPTp) o.

3. CONCLUSION

There are positive signs that the fight against malaria is yielding results, and we may see a sustained reduction in malaria cases and deaths globally by 2023. The reason for this is that there is more funding for preventive measures, better access to treatment, and innovative tools such as insecticide-treated bed nets and vaccines. Nevertheless, it's critical to stay watchful and maintain these efforts to eliminate malaria entirely. By collaborating, we can establish a healthier and safer world for everyone. In conclusion, biological weapons are a highly effective and eco-friendly way to control mosquito populations in urban areas. By using natural substances like Bti, *Metarhizium anisopliae*, and *Toxorhynchites*, we can reduce the spread of deadly diseases without harming the environment or other wildlife. It is important to use these biological weapons responsibly and in accordance with local regulations to ensure that they are used safely and effectively.

ABSTRACT

Today, theoretical computational tools are used to predict behavior. Add corrosion inhibitors to metal surfaces to avoid the energy consumption and expense of experimental testing. This work aimed to predict the inhibitory effects of certain furan derivatives in acidic media by comparing their intrinsic antiseptic properties and behavior. The anti-corrosive properties were studied by using quantum chemical calculations. Density Functional Theory (DFT), lowest unoccupied (ELUMO) and highest occupied (EHOMO) molecular orbital energies, energy gap (ΔE), chemical hardness (η), softness (σ), electronegativity (χ), electrophilicity (ω) and nucleophilicity (ϵ) have been calculated and discussed.

Keywords: Furan Derivatives, Corrosion, DFT, Prediction.

1. INTRODUCTION

Corrosion still has a huge economic impact in most industrial countries today, accounting for about a percentage point of the gross domestic product that is why the study of the inhibition of corrosion of metals remains a fertile area for scientific research. Is for finding realistic solutions for the probable problem consequences of metals corrosion phenomena such as environmental pollution, industrial damage and so is economic loss 1.

Computer software is now becoming a widely used and trusted tool for explaining the behavior of corrosion inhibitors in different media and metal surfaces. Density functional theory (DFT) is a computational modeling method commonly used to study the intrinsic properties of molecules. For inhibitors, it is mainly used to predict chemical properties, such as the highest occupied molecular orbital–lowest unoccupied molecular orbital (HOMO–LUMO) energy gap, chemical hardness, softness, electronegativity, chemical potential, proton affinity, electrophilicity and nucleophilicity of chemical species.

In our work, theoretical studies were investigated to predict the efficiency of three selected furan derivatives: furan-2-carbaldehyde (FF1), 5-(hydroxymethyl) furfural (FF2), and 5-(hydroxymethyl) furoic acid (FF3). Firstly, the intrinsic properties such as the EHOMO–

ELUMO energy gap (ΔE), chemical hardness (η), electronegativity (χ), the fraction of electrons transferred (ΔN), total negative charges and dipole moment of FF1, FF2, and FF3 were studied by using quantum chemical calculations.

2. COMPUTATIONAL DETAILS

Employing the Gaussian 03W program package, the density functional theory (DFT) calculations were performed on the studied furfurals derivatives FF1, FF2, and FF3 in gas and aqueous phases. All molecules were geometrically optimized using the DFT/B3LYP method associated with 6-31G++ (2d,p) basis sets, which is widely used in the investigation of organic corrosion inhibitors [2]

These include the lowest unoccupied (ELUMO) and highest occupied (EHOMO) molecular orbital energies, as well as gap energy (ΔE , Equation (1)), electronegativity (χ , Equation (2)), hardness (η , Equation (3)), fraction of electrons transferred (ΔN , Equation (4)), electrophilicity (ω), nucleophilicity (ε) and dipole moment (μ) [53]. Furthermore, the frontier molecular orbitals (i.e., HOMO and LUMO) repartitions and 2D electrostatic potential plots of each furfural derivative were calculated and figured.

$$\Delta E = ELUMO - EHOMO$$

$$\chi = -1/2 (ELUMO + EHOMO)$$

$$\eta = 1/2 (ELUMO - EHOMO)$$

$$\Delta N = \varphi - \chi/2 \times \eta$$

DFT Performances

The quantum molecular results summarized in Tables 1 and 2 aim to describe in detail the energetic and structural characteristics of the studied molecules. The quantum chemical parameters calculated using the HF/6-31G++ (2d,p), MP2/6-31G++(2d,p), and B3LYP/6-31G++(2d,p) methods for the inhibitors in aqueous and gas phases.

HOMO and LUMO Energies and Derived

The highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) of a chemical molecule is important in defining its reactivity. Compounds FF1, FF2, and FF3 show a significant contribution of p orbitals at the cyclic level (furan ring), consisting of an aromatic ring with five atoms including oxygen atoms [3], [4].

Figure 1. The HOMOs and LUMOs of inhibitor molecules in the gas phase using the DFT/B3LYP/ 6-31++G(2d,p) method.

Figure 2. The HOMOs and LUMOs of inhibitor molecules in the aqueous phase using the DFT/B3LYP/ 6-31++G(2d,p) method

3. CONCLUSION

Finally, different basis sets were used for DFT calculation to compare and evaluate the corrosion inhibition efficiency of three furan derivatives, namely furan-2-carbaldehyde, 5-hydroxymethylfurfural, and 5-hydroxymethyl furanic acid. Theoretical vibrational studies confirm that all these compounds have different functional groups (aldehyde and carboxyl). Neutral and split forms are optimized and checked. The results calculated using DFT show that FF3 has a smaller electronegativity value compared to FF2 and FF1. Therefore, in terms of the reactivity of these compounds, FF3 is more inclined to act as an electron donor.

COMPARISON OF THE ENGINEERING PROPERTIES OF DGB MIXES WITH COAL ASH USING NATURAL FIBERS

Dr. Ramireddy Sushmitha

Assistant Professor, Department of Civil Engineering, G. Pulla Reddy Engineering College (Autonomous), Kurnool, Andhra Pradesh, India-518007

S.V Garata Reddy

Assistant Professor, Department of Civil Engineering, G. Pulla Reddy Engineering College (Autonomous), Kurnool, Andhra Pradesh, India-518007

ABSTRACT

Coal based thermal power plants have been a key source of power generation in India. The prime waste product of coal thermal power plants is y ash and bottom ash. Heavy dumping of these waste products causes environmental pollution to air, water, and land. The research work is to determine the use of ash namely coal ash as a mineral filler, with natural fibers like coconut coir fiber, jute fiber to improvise the engineering properties of bituminous paving mixes. To strengthen the mix, fiber is added in varying percentage by weight of mix. Marshall Stability test is performed to study the variation in Marshall characteristics of the mixes when fiber % is varied.

Keywords: Bitumen, Coal Ash, Y Ash, Marshall Stability Test, Coconut Coir Fiber, Jute Fiber.

1. INTRODUCTION

Pavements or Highways or Roads are regarded as country's backbone, upon which its upswing and progress depend on. All countries normally have a series of programs for building a new road infrastructure or emerging the existing one. Construction of both flexible and rigid pavement include a gross amount of investment to reach better performance oriented and smooth quality of pavement that will endure for long time. In India, where highways are considered as the primary function of transportation, Government of India has been investing a huge amount of money for developing the pavement construction and maintenance. A detailed engineering study may retain significant amount of investment and pavement materials, which in turn achieve a reliable performance of the in-service highway. Regarding flexible pavement, two major facts are taken into considerations i.e., pavement design and mix design. The present research study is focused on engineering properties of bituminous mixes prepared from alternate or nonconventional materials.

Bituminous pavement comprises of a mixture of stone chips, graded from nominal maximum aggregates size (NMAS), through the fine fraction smaller than 0.075 mm mixed with appropriate amount of bitumen that can be compacted adequately with smaller air voids and will have adequate dissipative and elastic properties. The aim of bituminous mix design is to determine the fair proportion of bitumen and aggregates fraction to yield a mixture that is effective, durable, reliable, and economical.

2. Objectives of the research work:

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

1. This experimental study is focused to enable the most appropriate use of coal ash as nonconventional aggregate.
2. The adequate performance in the field of fatigue, moisture susceptibility, and creep value with addition of natural fibers (Coconut coir and jute fiber) as an additive is to be studied experimentally.
3. The possible effects of fiber on bitumen mixes are taken into consideration, and comprehensive study is done to find the optimum fiber content.

3. SCOPE OF THE STUDY

1. The scope of this study is to use coal ash as a fine material in HMA mix design.
2. Utilization of non-conventional materials like coal ash and natural fibers (Coconut coir and jute fiber) by using with different percentages to determine the engineering properties like:

- Marshall stability value.
- Marshall ow value.
- Air voids content.
- Voids filled with bitumen (VFB).

4. LITERATURE REVIEW

Ali N et al. (1996) conducted experimental study to observe the outcome of y ash on the mechanical properties of bituminous mixtures. Also evaluated the significant effect of using y ash in improving performance characteristics and modifying pavement distress. In this study, four types of specimens with various percentage of y ash fractions were studied. The properties such as permanent deformation, resilient modulus, creep, and fatigue were calculated at three different temperatures. Moisture induced damage tests were also carried out to assess moisture induced damage. The pavement performance was predicted by VESYS model. Results indicated that y ash as a mineral filler can be used to increase resilient modulus characteristics and stripping resistance. The addition of y ash did not reduce field performance of asphalt concrete mix in terms of rut depth and serviceability index but with the increase in temperature the sum of surface cracking also increased in the pavement.

Vasudevan (2013) conducted a test on Performance characteristics of Bottom ash in HMA (Hot Mix Asphalt). The objective of this research is to use the Bottom ash as aggregates in sub bases, bases, and pavement layer. This research is motivated with three parts objectives for evaluating the stability of bitumen mixture which are prepared form certain percentage of bottom ash using Marshall Method, determining physical characteristics of bottom ash when it was mixed with bitumen and evaluated the improvement of engineering properties of the Marshall cube in terms of texture and appearance. Based on the experimental results, the sample with bottom ash is superior to conventional samples in terms of stiffness, strength, and the sample ow. Subsequently, the pavement will become stronger and can withstand if loaded high traffic load. However, there are drawbacks with the usages of coal bottom ash as mineral filler where the air void content increased which cause in reduction of density in the mixture.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Hadiwardoyo and Pranowo (2013) studied that the failure at the surface layers of road is due to the change in temperature and the load of the traffic. Structural. An experiment on short coconut fibers in bitumen mix is performed. With various percentage of coconut fibers ranging from 0.5% to 1.50% with the increment of 0.25%. The fiber size was also varied with 5mm, 7.5mm, 10mm, and 12.5 mm. The bitumen characteristic with coconut fibers is tested. From the results obtained in Marshall properties test it is found that the Marshall stability increased by 10-15%, when 0.75% of fiber content and 5 mm of fiber length was added by weight of the mixture. It is also observed that with the addition of fiber in bitumen, change the bitumen property with a lower penetration value. Debashish (2007) studied the effect of indigenously available sisal fiber on SMA and BC mixture. Sisal fiber is considered as an additive for BC mix and stabilizing agent for SMA mix. Fiber content varied from 0% to 0.5% by weight of total mix whereas binder content was varied from 4% to 7%. For mineral filler y ash, is used as it has shown satisfactory result at the initial stage of experiment. For the performance test the BC and SMA mixes were subjected to various test such as Drain down test, Static Creep test and Static Indirect Tensile Strength Test. From the Marshall properties test it was observed that addition of fiber helps to improve the Marshall Stability and indirect tensile strength, it also reduces the Drain down. It is observed that the indirect tensile strength of SMA mixture is better than BC mixture. From Marshall test it is found that the optimum binder content for BC and SMA were 5% and 5.2% respectively whereas optimum fiber content were 0.3%. Kumar et al. (2007) studied the performances of the SMA mixture modified with crumb rubber modified checkonce binder (CRMB) and low viscosity binder coated jute fibers. The performance of SMA mixture were assessed by conducting two different methods of drain-down, durability test, moisture susceptibility test, fatigue life tests and rutting test. The characteristic of modified SMA prepared with coated jute fiber and with other patented fibers are compared. From the test observation it is concluded that fiber content of 0.3% by weight of the mix improve the Drain-down property of the mix.

Zeng and Ksaibati (2003) examined the moisture induced damage of bitumen mixtures comprising bottom ash. Eight bitumen mixtures made with one type of bitumen cement, two kinds of aggregate, three sources of bottom ash, and lime additive were estimated by using the principles written in AASHTO T283. The addition of lime considerably upgrade the moisture induced damage of the asphalt mixtures as measured by TSR (recommended TSR value should be greater than 80%). Asphalt mixtures with the stone chips had higher indirect tensile strength (ITS) values as compared to the limestone aggregate in dry condition. The addition of lime or bottom ash did not significantly change ITS values. Putman et al. (2004) studied the use of waste fiber in stone mastic asphalt mixture (SMA). Waste tire and carpet fibers are used as an additive to stabilize the excessive drain-down due to relatively high air void in SMA. Also studied the performance characteristics of SMA mixtures prepared with waste tire and carpet fibers. A comparative study has been done between SMA modified with tire and carpet fibers and with other mixes prepared with cellulose and polyester. From the observation it is found that the sample containing carpet and tire fibers, were effective in stopping unnecessary drain-down of the SMA mix.

5. MATERIALS USED IN THE STUDY

In this study following materials are taken for the preparation of bituminous mix.

- Stone chips (as coarse aggregate)

- Fly ash (as mineral filler)
- VG-30 (as bitumen binder)
- Jute fiber (as additives)
- Coconut coir fiber (as additives)

6. EXPERIMENTAL SETUP

6.1 Marshall Stability Test:

- The Marshall stability and flow test provides the performance prediction measure for the Marshall mix design method.
- The stability portion of the test measures the maximum load supported by the test specimen at a loading rate of 50.8 mm/minute.
- Load is applied to the specimen till failure, and the maximum load is designated as stability.
- During the loading, an attached dial gauge measures the specimen's plastic flow (deformation) due to the loading.
- The flow value is recorded in 0.25 mm (0.01 inch) increments at the same time when the maximum load is recorded.

6.2 Specimen Preparation:

- Approximately 1200gm of aggregates and filler is taken for the preparation of specimen.
- Bitumen is heated to a temperature of 160°C with the first trial percentage of bitumen (say 5 by weight of the mineral aggregates).

Figure 1. Marshall Stability Test

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

- The mix is placed in a preheated mould and compacted by a rammer with 75 blows on either side.
- Without any disturbance keep the mould at 24 hours.
- Then again keep the mould for 30 minutes in water and then weight the mould.
- Keep the mould into the Marshall equipment and test the mould. Then, note down the Marshall stability value and Flow value.
- The weight of mixed aggregates taken for the preparation of the specimen may be suitably altered to obtain a compacted thickness of 63.5 ± 3 mm.
- Vary the bitumen content in the next trial by +1 and repeat the above procedure.
- The fibers are cut into specified lengths of 10mm.
- Required quantity of bitumen VG-30 and fiber pieces are added to the aggregate mixture and thoroughly mixed.

In this experiment, the resistance to deformation of a Marshall cylindrical specimen of DBM mixture is measured. The specimen is loaded diametrically at a deformation rate of 50 mm/min. Here are two major features of the Marshall method of mix design are:

6.3 Stability and flow values

Figure 2. Specimen preparation

6.4 Voids analysis

- Different samples are prepared using Jute and Coconut coir fiber as additives for 5%, 1%, 1.5% in bitumen content.
- Marshall stability for bituminous mix is defined as the maximum resistance carried by specimen at a standard temperature of 60°C . The flow value is recorded when the specimen deformed under maximum.

Figure 3. Bitumen moulds

Figure 4. Specimen samples

Figure 5. Observation of readings

For the moulds prepared, the above are calculated and the effect of fiber is studied and checked whether each parameter satisfies the limits are not.

7. ANALYSIS OF RESULTS AND CONCLUSIONS

7.1 Parameters used in the Study

Some of the parameters considered for this study are:

- Marshall stability value.
- Marshall flow value.
- Air voids content.
- Voids filled with bitumen (VFB).

7.1.1 Theoretical Specific Gravity of Bitumen Mix (G_t)

$$G_t = \frac{W_1 + W_2 + W_3 + W_4}{\frac{W_1}{G_1} + \frac{W_2}{G_2} + \frac{W_3}{G_3} + \frac{W_4}{G_4}}$$

where,

W₁ = percent by weight of coarse aggregate in total mix.

W₂ = percent by weight of fine aggregate.

W₃ = percent by weight of weight of filler.

W₄ = percent by weight of bituminous binder in total mix.

G₁ = Specific gravity of coarse aggregate.

G₂ = Specific gravity of fine aggregate.

G₃ = Specific gravity of filler.

G₄ = Specific gravity of bituminous binder.

7.1.2 Bulk Specific Gravity of the Bitumen (G_m)

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

The bulk specific gravity or the actual specific gravity of the mix G_m is the specific gravity considering air voids and is found out by

$$G_m = \frac{W_m}{W_m - W_w} \quad (1)$$

where,

W_m = Dry weight of sample.

W_w = Wet weight of sample.

It is obtained by measuring the total weight of the mix and its volume. Volume is determined by measuring the dimensions of the sample or for better accuracy it can be measured by the volume of water it displaces. However, while the sample is immersed in water, some water may be absorbed by the pores of the mix.

7.1.3 Air voids

It is the total volume of the small pockets of air between the coated aggregate particles through-out a compacted paving mixture, expressed as a percent of the bulk volume of the compacted paving mixture. The amount of air voids in a mixture is extremely important and closely related to stability, durability, and permeability.

7.1.4 Volume of Bitumen

It is the volume of bitumen binder in the mix that has been absorbed into the pore structure of the aggregate. This volume is not accounted for the effective bitumen content.

7.1.5 Voids in Mineral Aggregates

The total volume of voids in the aggregate mix (when there is no bitumen) is called Voids in Mineral Aggregates (VMA). In other words, VMA is the volume of intergranular void space between the aggregate particles of a compacted paving mixture. It includes the air voids and the volume of bitumen not absorbed into the aggregate. VMA is expressed as a percentage of the total volume of the mix.

$$VMA = V_A + V_B \quad (2)$$

where,

V_A = Air voids in the mix.

V_B = Volume of bitumen.

7.1.6 Voids filled with Bitumen (VFB)

VFB is the voids in the mineral aggregate frame work filled with bitumen binder. This represents the volume of the effective bitumen content.

where,

V_b = Volume of bitumen.

VMA = Voids in Mineral Aggregate.

7.1.7 Effect of coal ash on DBM

The percentage of bitumen content is varied as 5%,6%,7% by weight. Coal ash is taken as filler. The variation in properties is tabulated below:

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Table 1. Effect of Coal ash on DBM mix

Bitumen (%)	Dry Weight (g)	wet Weight (g)	Thickness (cm)	Diameter (cm)	Marshall Stability (kN)	Flow Value (cm)	Air Voids (%)	VFB (%)
5	1261	755	6.3	10.1	5.49	4.3	5.962	67.62
6	1268	760	6.3	10.1	5.71	4.8	5.61	68.33
7	1276	765	6.3	10.1	7.73	5.3	4.90	71.72

7.1.8 Marshall Stability Value

Marshall stability measures the maximum load sustained by the bituminous material at a loading rate of 50.8 mm/minute. The variation of marshall stability value with bitumen content is illustrated in Fig 6.

Figure 6: Marshall Stability Value

It is observed that the stability value increases with increase in bitumen content from 5% to 7%. The Marshall stability value is obtained for 7% bitumen and is 7.73 kN.

7.1.9 Marshall Flow Value

The flow value refers to the vertical deformation when the maximum load is reached. The flowvalue variation with bitumen content is shown in Fig 7. It is observed that as the Bitumen increases, the flow value increases.

Figure 7: Marshall Flow Value

7.1.10 Air Voids

The amount of air voids in a mixture is extremely important and closely related to stability, durability, and permeability. Fig 8 represents the air voids (%) variation with bitumen content.

Figure 8. Air voids

It is observed that the air voids % decreases with increase in bitumen content (in %). The value of air voids is 4.90% obtained for 7% bitumen content.

7.1.11 Voids filled with bitumen

VFB is inversely related to air voids and hence as air voids decreases, the VFB increases. The decrease of VFB indicates a decrease of effective bitumen film thickness between aggregates, which will result in higher low-temperature cracking and lower durability of bitumen mixture since bitumen perform the filling and healing effects to improve the flexibility of mixture.

Figure 9. Voids Filled with Bitumen (VFB)

It is observed that the VFB values increases with increase in bitumen content (in %). The value of VFB value is 71.72% obtained for 7% bitumen content.

7.2 Effect of Coal Ash and Jute Fibre on DBM mix

In order to enhance the engineering properties of bitumen content, jute fibers are used as additive. Jute fiber is added in 0.5% ,1%,1.5% by weight for every bitumen

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

content(5%,6%,7%).Table 5.5,5.3,5.4 indicate the variation in the engineering properties considered for study.

Table 2. Effect of 0.5% of jute fiber and coal ash

Bitumen (%)	Dry Weight (g)	wet Weight (g)	Thickness (cm)	Diameter (cm)	Marshall Stability (kN)	Flow Value (cm)	Air Voids (%)	VFB (%)
5	1266	750	6.3	10.1	5.59	3.2	5.84	69.72
6	1278	765	6.3	10.1	7.14	3.5	5.69	71.13
7	1290	775	6.3	10.1	7.85	4.2	4.90	78.35

8. CONCLUSIONS

- For 7% bitumen content and 1.5% of fiber content (by weight), the marshall stability value is more for coconut coir fiber (13.04kN) compared to jute fiber (12.25kN).
- It is inferred from the experimental results that the flow value is within the limits of (2-4mm) when the bitumen content is 5% and the fiber content is 0.5%.
- Excessive air voids in the mixture results in cracking and too low air voids may induce plastic flow. Here the experimental results show that the air voids % decreases as the fiber content increases. But maximum values of air voids satisfying the permissible limits (3-5%) for different bitumen content and fiber content is obtained for coconut fiber.
- Air voids percentage and VFB values are inversely proportional, it is concluded from tests that with increase in fiber content, VFB value increases for both fibers. But the limits of (75%-85%) is maximum satisfied for coconut fiber content in mixture.
- Among the two natural fibers used, based on marshall mix design, coconut coir fiber gives best results which are within required specified limits for 7% Bitumen content and 0.5% fiber content by weight.

ABSTRACT

This study investigated the Effects of Fieldwork Strategy on Senior Secondary School Students Academic Performance and Interest in Geography, Katsina State, Nigeria. Three research objectives, three research question were raised and three null hypotheses were formulated and tested at 0.05 significant level. The study used quasi experimental and control group design involving pre and posttests. The target population for the study covered 2,251 senior secondary school year II students in the study area. A total number of 106 students from two intact classes of SS II were purposively selected and used as sample of the study. One school were selected as the experimental group, while the other one served as the control group. The instruments were validated by experts in science education and psychology. The instruments with reliability coefficients of 0.6 and 0.8, namely Geography Achievement Test and Geography Interest Questionnaire were used for data collection. Research questions were answered descriptively using mean and standard deviation while null hypotheses were tested inferentially using t-test, Mann Whitney U-Test and Kruskal Wallis H-Test were used. Findings of the study revealed that there was significant difference in the academic performance of students exposed to the Fieldwork strategy and lecture method in favour of experimental group. There was also significant difference in the interest of students exposed to the same strategy and those taught using lecture method. Gender difference exist in the performance and interest of students exposed to Fieldwork strategy. On the bases of the findings, the study recommended that the use of Fieldwork Strategy in teaching geography in school should be encouraged by State Ministries of Education through training of teachers in form of seminars and workshops on how to use Fieldwork in teaching periodically. Similarly, Katsina State Ministry of education should ensure adequate monitoring of teachers when using Fieldwork Strategy for improving achievement and interest towards school subjects with immediate effect.

1. INTRODUCTION

Geography is considered as the study of the earth's environments and peoples, and the interactions between them. Geography as an academic subject, is geared towards teaching the interrelationships among phenomenon on the earth's surface and those in the atmosphere (Abdulkarim, 2010). It enables students to explore and understand the relationship between human beings and the earth through the study of space, place and environment. Geography, as a school subject is a multidisciplinary subject that cuts across a wide range of subject areas. Basically, the subject entails the study of the natural environment and its relationship with man, hence the nomenclature of physical and human Geography (Mutum, 2019). Human geography is a major sub discipline within the wider subject field of geography. It is referred to as the study of man's reciprocal relationship with his environment. It looks at the impact and behavior of people and how they relate to the physical world. Areas of human geography includes; population, settlement, urban, medical, agriculture, resource, industry and cultural geography (Parvez, 2018).

Worldwide, the environment offers diversity and variety that are stimulating and exciting places in which to live and learn. Bruce (2011), stated that environments are significant as they help learners to develop sensitivity to their immediate locality and by this understanding strengthened their own sense of identity. He adds that they also help them keep to their own reality as an important element in their schooling. Geography is one of the activity-based school subjects. The effectiveness of teaching in school can be measured by examining the method of teaching applied by teachers and the performance of students in school examination. In the measurement of students' academic performance in geography, as a school subject, various tasks are undertaken within and outside the classroom; the effectiveness of these activities lie in the instructional methods used by the teacher (Silas et al., 2016).

Instructional methods refer not only to the ways, approaches, procedures and kinds of activities which teachers and students engage in the interactive process with a view to inducing, inspiring and facilitating learning for the purpose of accomplishing instructional objectives. Teaching methods also include the utilization of appropriately selected curriculum resources materials, content and learning experiences, motivational strategies, educational field-trips, evaluative and implementation strategies, the application of learning theories and the demonstration of knowledge of educational psychology and aspects of developmental psychology in the teaching-learning process (Okam, 2019).

A variety of methods and approaches are advocated for teaching. Most of these methods and approaches are in use in the Nigerian school's system and each of them provides something useful and worthwhile to a capable and enthusiastic teacher. None of the methods and approaches is error-proof; each of them is associated with a number of advantages and disadvantages (Okam, 2019). These include: Lecture method, Demonstration method, Discovery method, Project method, Problem-solving method, Heuristic method, Inquiry method, Discussion method, Laboratory method, Fieldwork method among others.

The term Fieldwork, is seen to be the "active engagement with the external world"; whether every activity described as fieldwork fits the criteria of "active engagement" is debatable (Mohammed, 2016). Amosun (2016) stated that, Fieldwork includes fieldtrips, field teaching, field research or field camps or indeed "any arena or zone within a subject, where outside the constraints of the four walls of classrooms' settings, supervised learning can take place via

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

firsthand experience”. Fieldwork in the context of this study is the art of taking students to the field to gather data on population, settlement and agriculture. In spite of all the views that geography is based-learned in a field, most geography teachers are having a view that teaching physical aspects of the subject such as rivers and their features, weathering and their features, soil and soil erosion, mountains, deserts and their various landforms and the like are the only areas where fieldwork is required in teaching geography. In human geography, topics such as settlements and their types, transportation system, industries, agriculture, population among others are traditionally taught in the classroom settings using traditional teaching strategies (lecture among others).

Geography students are expected to be exposed to different aspects of their curriculum outside their classrooms. This is because geographers study the totality of the earth’s phenomena. The phenomena they study are outside the classroom. Geography entails integration of fieldwork to study natural phenomena. “The environment is the laboratory of geographers” (Amosun, 2016). Its practical aspects and their dimensions are carried out there. One of the objectives of teaching geography is helping learners understand their immediate environment as well as that of the universe. This cannot happen in rigidly planned classroom activities where the teacher and text books are the only sources of information. Nabors et al., (2009) disclosed that school learning should be authentic and connected to the world outside of school, not only to make learning real but also to develop in to a learner’s ability to apply knowledge in real-world settings.

Majority of geography teachers are not using fieldwork teaching strategy as noticed in many Secondary Schools in this country (Awolusi, 2012; Falana, 2015; & Amosun, 2016). Some teachers are only exposing their students when teaching some topics under physical geography such as rocks, Action of running water, Flooding, Soil erosion and so on. It is difficult to see a teacher organizing a fieldwork while teaching human geography topic such as population, settlement, trade, tourism and so on. Amosun, (2016) in his work titled “Making Secondary School Geography come Alive in Nigeria: A case for fieldwork in Oyo State” found that a whopping majority of students from five secondary schools in Ibadan never participated in fieldwork and field report writing. Teachers and schools hardly get their students engaged in fieldwork. This indicates that fieldwork is not fashionable among them. Katsina State, where Baure Zonal Education Quality Assurance is located may not be exempted from this anomaly.

Academic Performance refers to the display of knowledge attained or skills developed by students in the school's subject usually designed by test scores or by marks assigned by the teachers which can either be low or high (Yakubu, 2016). The performance of candidates in the West African Examination Council (WAEC) in Nigeria is becoming poorer every year (Ezema, 2014; Salisu, 2015; & Yakubu, 2016). The WAEC chief examiner's report (2017) noted a decline in performance of Geography students over the previous years. An analysis of students result in geography in the National Examination Council of Nigeria (NECO) for a period of five years is presented in Table 1.1

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Table 1. Candidates' Performance in Geography (SSCE) 2015-2019, Nigeria

Year	No. Sat	No. Passed (A1-C6)	%	Passed (D7-D8)	%	Failed (F9)	%
2015	711,689	163,438	22.96	361,620	51	149,877	21
2016	674,686	153,613	22.77	460,333	68	32,401	5
2017	703,316	345,921	49.18	317,648	45	33,027	5
2018	671,991	432,239	64.32	206,905	31	28,010	4
2019	431,230	297,495	68.99	112,489	26	19,689	5

Source: (National Examination Council of Nigeria, 2020).

The result presented in Table 1.1 actually revealed a steady decrease in the number of students that sat for the examination and an increase in the percentage of students with credit and pass and a decrease in percentage failed, but the percentage passed and failed is still a source of worry, hence the need to improve on the teaching strategies employed in the schools in order to improve students' performance, as poor teaching method and unqualified teachers are some factors highlighted out as problems affecting students' performance (Obasi, 2011).

Interest in this study is a feeling of curiosity or concerned of subject, topic, (in this case, population, settlement and agriculture) that make attention towards it, Salisu, (2015) seen interest as "a psychological state of engagement, experienced in the moment and also a predisposition to engage repeatedly in particular ideas, events, or objects over time". Interest simultaneously diversifies one's experience and focuses his experience; leading him to pay attention to only certain things and not to some other things that tend to stimulate the person's attention. In recent years researchers have begun to build a science of interest, what makes things interesting, and how we can cultivate interest in ourselves and in others.

Gender has remained a debating issue and has also remained relevant in education because it has been linked to performance and participation in certain profession. Evidence from research findings indicate gender gap achievement in favour of males (Ezema, 2014; & Silas Et'al, 2016), while some revealed that gender is not a factor in teaching and learning (Amosa, 2013; Kabirat, Et'al, 2016; and Wada, 2015). This generated a gap and justifies the need to determine the extend gender as a variable influenced student's interest and performance in the study.

It is against this background that the researcher intends to investigate the effect of fieldwork and inquiry strategies on secondary school geography students' academic achievement and Interest in Baure Zonal Education Quality Assurance.

2. STATEMENT of THE PROBLEM

Poor academic performance of secondary school student in Geography (WAEC Chief Examiners Report 2019) has been linked to poor Teacher's performance in terms of accomplishing the teaching task, which have been attributed to instructional strategy. The problem of poor performance to a large extent has been attributed to ineffective teaching employed by geography teachers especially traditional lecture method which is largely dominated by teacher talk and chalk (Ezema, 2014; Salisu, 2015; & Yakubu, 2016).

Most Nigerian secondary school geography teachers still use the Lecture approach in teaching human geography, especially in Baure Zonal Education Quality Assurance. Empirical studies

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

had highlighted some intervention measures that could stimulate the study of geography, like games, simulations, peer methods and fieldwork. Unfortunately, these had been in the areas of Physical aspects of Geography. These create a gap and the need to examine the effect of fieldwork and inquiry strategies on students' performance and interest among senior secondary school geography (human aspect).

However the problem of not employing the activity based teaching strategies like Fieldwork and Inquiry in teaching human geography in most Nigerian secondary schools has made the learning of human geography concept difficult. This worrisome state of affairs applies largely in Baure Zonal Education Quality Assurance of Katsina State, where human geography is taught largely by traditional lecture method with no attempt at practical approach suggested by NERDC (2014). In addition, in utilizing these methods, teachers considered the cognitive, aspect of learners and neglect the affective aspect (interest). There is a need therefore to provide an alternative teaching strategy which will hopefully incorporate cognitive, affective and psychomotor domains of students like the use of fieldwork and inquiry strategy. It is on this basis that, the research investigated the Effect of Fieldwork and Inquiry strategies on Secondary Schools Geography Students' Academic Performance and Interest in Baure Zonal Education Quality Assurance (ZEQA), Katsina State.

3. THEORETICAL FRAMEWORK of THE STUDY

This work is based on the constructivist approach to learning emanated from the works of Bruner (1966) and Piaget (1973) (Dewey, 2012). The theory in reaction against the largely lecture based method of instruction which have significant limitation recognizes that the best way to learn is by having students construct their own knowledge instead of having someone to do it for them. It is a learner-center approach that emphasizes the importance of individual activity constructing their knowledge and understanding with guidance from the teacher. In the constructivist view, teachers should not attempt to simply pore information in to children's mind. Rather children should be encouraged to explore their world, discover knowledge, and reflect and think critically with careful monitoring with meaningful guidance from the teacher (Jia, 2010). Fieldwork teaching strategy can best suit this assertion.

Scientists and philosophers like Dewey (1916), Piaget (1973), and Vygotsky (1978) have interpreted constructivism according to their own experience. In relation to that, the conclusion is that the learners' knowledge is their own life, their style and their life is an experience they get. Therefore, the teaching and learning process must be related to the practical real world so that the classroom is designed and shaped in such a way that teacher and students can share their knowledge and experience actively. The theory equally advanced that learning is an active process of creating meaning from different experiences with the teacher as a guide to help them along the way. This is the basis of constructivist learning theory.

Therefore a constructivist teacher creates a friendly environment for learning in which students can become more engaged in interesting activities (like fieldwork) that encourage and facilitate learning. The teacher guides students as they approach problems, encourage them to work in groups, to think about issues and questions, support them with encouragement and advice as they tackle problems, adventures, and challenges that are rooted in real life situations (Zhou & Brown, 2017). Teacher's role thus, is mainly to facilitate learning and cognitive growth.

As the father of constructivism theory, Piaget constructed a major principle in his constructivism theory. The main principle in Piaget's theory is that knowledge must be built by

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

students as the active creator of that knowledge. This means that students must be active in all their learning activities; they should be able to pick up and dig new information and process it according to their needs. They are not expected to be passive. Piaget's cognitive theory of learning is referred to as "stage theory" of cognitive development. According to Piaget as cited by Zhou and Brown, (2017), children develop knowledge by inventory or constructing reality out of experience and thus mix their observation with their ideas about how the world works. Piaget (1973) believed that for people to learn, they must assimilate and accommodate. He opines that at each stage of development people use a distinction underline logic or structure of reasoning to guide their thinking. Geography is a natural and practical subject which is taught both in the classroom and in the natural environment. When geography teachers take out students on fieldwork outside the school environment for the purpose of teaching the students, it gives them the opportunity to meaningfully construct knowledge and understand the material while guiding their learning.

4. OBJECTIVE of THE STUDY

The study was guided by the following objectives to:

1. Determine the effect of fieldwork strategy on secondary school Geography students' academic performance in human geography in Baure Zonal Education Quality Assurance.
2. Find out the effect of fieldwork strategy on secondary school student interest towards human geography.
3. Determine the effect of fieldwork and strategy on gender interest among secondary school students in human geography.

5. RESEARCH QUESTIONS

The following research question were formulated to guide the research.

1. What is the difference in the mean scores of secondary school students taught human geography using fieldwork strategy and their counterparts taught the same concept using lecture method?
2. What is the difference in the mean interest score of secondary school students taught human geography using fieldwork strategy and their counterparts taught using lecture method?
3. What is the difference in the mean interest score of male and female secondary school geography students exposed to fieldwork strategy?

6. RESEARCH HYPOTHESES

The following null hypotheses were formulated to guide the research.

- H₀₁**. There is no significant difference in the mean scores of secondary school students taught human geography using fieldwork strategy and their counterparts taught the same concept using lecture method
- H₀₂**. There is no significant difference in the mean interest score of secondary school students taught human geography using fieldwork strategy and their counterparts taught using lecture method

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

**III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy**

H03. There is no significant difference in the mean interest score of male and female secondary school geography students exposed to fieldwork strategy.

7. RESEARCH DESIGN

The study utilized pre-test, post-test quasi-experimental and control group design. The study has two groups; one experimental (EG) and one control (CG). Before treatment, the two groups were pre-tested (O1) to ensure selection of schools with comparative abilities. The experimental group were exposed to instructional treatment using fieldwork (X) for a period of six weeks. Control group were taught using traditional lecture method. The two groups were post-tested (O2) using the same instruments in pre-test.

The population for this study consists of all Senior Secondary two (SSII) students offering Geography in Baure Zonal Education Quality Assurance. There are twelve (12) Senior Secondary Schools with a population of two thousand two hundred and fifty-one (2,251) Geography students with a total number of nine hundred and eighty-five (985) male Students and one thousand two hundred and sixty-six (1266) female students.

The sample of this study covered a total number of 106 SSII students selected from two public senior secondary school offering geography in the study area. The two schools are GSSS Karkarku, and GSSS Fago. The schools are separated by not less than 20kilometers to minimize interaction effect. The choice of 106 students is in line with central unit theorem which prescribe that minimum of 30 participants is adequately enough to form a sample in an experimental study of this nature. In addition, Ker linger (1975), Tukman (1980) and Kajuru & Ado (2012) stated that in research of this nature, 10-15% of the entire population can be used as a sample. In each school intact class of SSII were sampled and used for the study. Details is presented in table 3.2

Table 3.2. Sample of the Study

Schools	Status	Male	Female	Total
A	Experimental Group.	27	24	51
B	Control Group.	32	23	55
	Total	59	47	106

The instruments for this research is Geography Performance Test (GPT) and Geography Interest Questionnaire (GIQ). The GPT instrument consists of thirty (30) items test adapted from West African Senior School Certificate Examination (WASSCE) conducted by the West African Examination Council (WAEC) from 2015 to 2019. All the 30 questions adapted from this instrument, which are objective (multiple choice) items in human geography with four options (A-D) out of which only one option is correct to the items, are based on the topics selected from SS II geography syllabus. The topics selected are; Population, Settlement, and Agriculture. These items measure objectives in the blooms cognitive domain of educational objectives.

Table 3.3. Table of Specification for GAT construction

3	Agriculture	40%	4	3	2	1	1	1	12
	Total	100%	9	7	5	3	3	3	30

Source: Adapted from Obeka (2013).

Key: K = Knowledge, C = Comprehension, A₁ = Application, A₂ = Analysis, S = Synthesis, E = Evaluation.

The Geography Interest Questionnaire (GIQ) is a 25 items interest inventory questionnaire adapted from Salisu, (2015) to determine the interest of students between and after treatment on concepts of human geography. The items were developed using Likert, (1970's 4-point rating scale involving strongly Agree (SA); Agree (A); Disagree (D); and Strongly Disagree (SD). Each option carries weight in the order of priority from four to one in positive interest responses and from one to four in negative interest on Human geography concepts by simply ticking one of the four options that suit their interest.

In order to determine the extent to which the instruments can measure the Academic Performance of Students in Human Geography, the GPT are securitized by the members of supervisory team for this study and five lecturers (Three from science and vocational education and two from Geography) in Umaru Musa Yar'adua University, Katsina. A copy of the developed items was submitted to each Science Education expert for validation. GIQ was validated by panel of three qualified experts with PhD. qualification in the field of psychology in Umaru Musa Yar'adua University Katsina. The scores of the students obtained from the pilot testing were analyzed using Cronbach Alpha and Spearman Rank Order Correlation where the common inter-item correlation coefficient r is obtained at 0.6 and 0.8 indicating that the instruments have consistency of the items, thus the instruments is said to be reliable for this study.

Data collection procedures begin with introducing the researcher and research assistants to ministry of education and secondary schools to be used in the study by means of introductory letter. Immediately after introduction, the researcher explains to the respondents the purpose of the study and the need for cooperation. Pretest was then administered before treatment.. The procedure for the research treatment is in four phases. The data collected were subjected to analysis at two different levels, VIS: the research questions were answered by using Mean and Standard Deviation. The hypotheses were tested at 0.05 alpha level using SPSS Package Version 25.1 as follows:

8. RESULTS

RQ1: What is the difference in the mean scores of secondary school students taught human geography using fieldwork strategy and their counterparts taught the same concept using lecture method?

Table 4.1. Mean and Standard Deviation of Academic Performance of Experimental I and Control Group

Variable	N	Mean	SD	SE	Mean D/F
fieldwork strategy	51	20.94	4.59	0.64	9.69
Lecture Method	55	11.25	2.94	0.39	

III. International Architectural Sciences and Applications Symposium
 September 14-15, 2023, Naples, Italy

Table 4.1 shows that experimental group has a mean of 20.94 and Standard Deviation of 4.59, while the mean of control group is 11.25 with standard deviation of 2.94 and a mean difference of 14.7. This shows that geography students taught human Geography using fieldwork strategy achieved higher academically, by mean score of 20.94, than their lecture group counterpart with mean score of 11.25.

RQ2: What is the difference in the interest score of secondary school students taught human geography using fieldwork strategy and their counterparts taught using lecture method?

Table 4.4. Mean Rank Interest Scores of the Subjects in the Experimental I and Control Group

Group	N	Mean Rank	Sum of Rank	Mean Difference
Fieldwork strategy	51	79.94	4077.00	
Lecture Method	55	28.98	1594.00	50.96
Total	106			

The Table 4.4 showed the change in interest of the subject toward Geography in experimental I and control group. From the Table, the mean rank value of 79.94 was obtained in experimental group I with sum of ranks of 4077.00. While in the control group, a mean rank value of 28.98 with a sum of ranks of 1594.00 was obtained. Difference in the mean rank signifies difference in the interest ability of the subject in geography due to exposure to fieldwork Strategy and lecture method. This shows that group taught human geography using Fieldwork strategy developed higher interest in Geography than group taught using lecture method as revealed in their mean rank score.

RQ3: What is the difference in the mean interest score of male and female secondary school geography students exposed to fieldwork strategy and inquiry method?

Table 4.8. Mean Rank Interest Scores of the Subjects in the Experimental Groups

Group	N	Mean Rank
Male Fieldwork	27	60.78
Female Fieldwork	24	54.38
Total	51	

The Table 4.8 showed the change in interest of male and female students toward Geography in experimental I and II groups. From the Table, the mean rank value of 60.78 was obtained among male students in experimental group I; the mean rank value of 30.98 was obtained among male experimental group I and the mean rank value of 47.61 was obtained among female experimental group II.

H₀₁. There is no significant difference in the mean scores of secondary school students taught human geography using fieldwork strategy and their counterparts taught the same concept using lecture method

Table 4.9. Results of t-test Analysis of Performance Scores of the Subjects in the Experimental and Control Groups

Variable	N	Mean	SD	T	DF	P	decision
----------	---	------	----	---	----	---	----------

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Fieldwork strategy	51	20.94	4.59				Sig
Lecture Method	55	11.25	2.94	13.01	104	0.01	

*Significant at $p \leq 0.05$ level of significant

Table 4.9 shows that the t-value computed is 13.01 and the p-value of 0.01 is observed at degree of freedom of 104. Since the p-value of 0.01 is less than the alpha value, there is a significant difference in the academic performance of the subjects in experimental and control group. Therefore, null hypothesis that states that there is no significant difference in the academic performance scores of geography students taught using Fieldwork Strategy and those taught the same concept using lecture method is rejected.

H02. There is no significant difference in the interest score of secondary school students taught human geography using fieldwork strategy and their counterparts taught using lecture method?

Table 4.12. Mann-Whitney U-test Rank Interest Scores of the Subjects in the Experimental I and Control Group

Group	N	Mean Rank	Sum of Rank	Man-Whitney U-test	P	Decision
Fieldwork strategy	51	79.94	4077.00	54.000	0.01	Sig.
Lecture Method	55	28.98	1594.00			

*Significant at $p \leq 0.05$ level of significant

From the Table Mann-Whitney U observed is 54.0 and the p-value observed was 0.01. Since the p-value of 0.01 is less than alpha value of 0.05, there is significant difference in the interest ability of the subject in geography and hypothesis is rejected.

H03. There is no significant difference in the mean interest score of male and female secondary school geography students exposed to fieldwork strategy and inquiry method?

Table 4.16. Kruskal-Wallis H-Test of interest among male and female students taught human geography using fieldwork, inquiry and lecture method.

Groups	N	Mean Rank	Sum of Rank	H-Value	P	Remark
Male Fieldwork	27	60.78	4077.00			
Female Fieldwork	24	54.38	3200.00			
Male inquiry	26	30.98	1594.00	16.99	0.01	Sig.
Female inquiry	19	47.61				

*Significant at $p \leq 0.05$ level of significant

The result in Table 4.14 shows that the Kruskalwallis observed was 86.64 and the p-value observed was 0.01 which is less than alpha value. Since the p-value of 0.01 is less than 0.05, there is significant difference in the Interest change among male and female students in the experimental groups, the null hypothesis was rejected.

9. SUMMARY of THE FINDINGS

From the result presented in this study, the summaries of the major findings are:

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

1. Significant difference exists in the mean scores of secondary school students taught human geography using fieldwork strategy and their counterparts taught the same concept using lecture method.
2. Significant difference exists in the interest score of secondary school students taught human geography using fieldwork strategy and their counterparts taught using lecture method.
3. There is significant different in the academic performance score of male and female secondary school students taught human geography using fieldwork strategy and those exposed to inquiry strategy.

10. DISCUSSION of FINDINGS

Significant difference exists in the mean scores of secondary school students taught human geography using fieldwork strategy and their counterparts taught the same concept using lecture method. This is supported by Ezema (2014), Silas et al, (2016), Omakaadejo, (2015), Yakubu, (2016). Ezema, (2014)'s finding reveals that Students exposed to Fieldwork performed significantly better than those exposed to the conventional lecture method. This finding gains further support from the work of Yakubu (2016) on effectiveness of Field based teaching strategy on students' Interest, Retention performance in climate change. The finding revealed that there is significant difference in the academic achievement of students exposed to Field based teaching strategy over the lecture method. Also Patrick (2010), investigated effects of field studies in learning outcome in Biology, The major findings of the study showed; a significance difference in process of science scores between pre-test and post-test of field trip students; a significance difference in process of science scores between students exposed to field trip experiences and these who were not exposed: a significant difference in Biology achievement test scores between students exposed to field trip experiences and these who were not; and a strong correlation between process of science score and Biology achievement score;

Also, in harmony with this findings, Nkereowajiro (2014), conducted a study on the impact of student's field trips on Academic performance in Agricultural science in selected secondary schools in Rivers state. The findings revealed that Field trip enhances knowledge of Agricultural processing methods, improves farm product utilization and contributes to species improvement and genetics. The performance level of student's senior secondary school III examination and students' overall performance in O' Level examination certificate in Agricultural science in Secondary Schools in Rivers state improved significantly ($P < 0.05$). Silas et al, (2016) on effect of fieldtrip strategy on senior secondary school students' Academic Achievement in Geography in Numan Educational Zone, Adamawa State, Nigeria. The findings of hypothesis on Academic achievements of students taught Geography using fieldtrip strategy and conventional lecture methods revealed that students who were exposed to field trip strategy had better scores in Geography than those who were taught using conventional method.

The finding comes contrary with Abul, (2007) who examined the effect of fieldwork teaching method on students' achievement in environmental education contents, in senior secondary school geography. The null hypothesis was that there is no significant difference ($p < 0.05$) in the mean academic achievement between high and low ability students in environmental education units of geography. What this implies is that, both the high and low ability groups performed well and are homogeneous in achievement. Significance difference exist in the

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

interest score of secondary school students taught human geography using Fieldwork Strategy and their counterparts taught using lecture method.

This finding is in agreement with that Yakubu, (2016); Ezema, (2014); Salisu (2015); and Silvanus and Silas, (2017). Result of studies conducted by Yakubu (2016) on the effect of field-based teaching strategy on interest, retention and performance in climate change among secondary school students in Anchau, shows that students taught geography using Field-based Strategy displayed greater interest in the Climate Change concept of geography than lecture group. This is also in harmony with Ezema, (2014)'s findings. The result of the data analysis indicated that, the effect of fieldwork on students' interest was significant. This finding is also supported by Salisu, (2015) who investigated impact of Animated Media Strategy on Students' Academic Achievement, Retention and Interest among Secondary School Geography Students in Weather Concepts revealed a significant difference in interest among subject taught using Animated Media Strategy and those exposed to lecture method. Subject in the experimental group shows high positive interest than subject in the control group. The difference in the interest observed can be attributed to the use of innovations in teaching experimental group as stated by Neumann et al, (2011).

There is significant different in the academic achievement score and interest of male and female secondary school students taught human geography using fieldwork strategy and those exposed to lecture method. This finding is in harmony with those of authority such as Ezema, (2014) and Silas et al, (2016) who in their separate studies in various discipline found that gender was significant in Students Academic Achievement and Interest. Silas et al, (2016) findings on effect of fieldtrip strategy on senior secondary school students' Academic Achievement in Geography in Numan Educational Zone, Adamawa State, Nigeria, revealed a significant difference between male and female students in experimental group. The difference in the achievement was in favor of the male students. Also, Ezema, (2014) findings revealed that gender was significant factor in students' overall achievement and interest in map reading geography. Silvanus and Silas, (2017) findings also indicate that the male chemistry students achieved higher than their female counterparts.

These findings come contrary with those of authorities such as Amosa, (2013), Salisu, (2015), Yakubu, (2016), and Usman, (2010) who in their separate studies in various discipline found that the application of instructional treatment on a mixed gender school population improves the academic achievement of students irrespective of gender. Amosa (2013) also affirmed that the gender of the learners is not a factor in teaching and learning: male students taught using community resources did not perform better than female students who were also exposed to the community resources. Salisu, (2015) revealed that male students taught Weather concepts using Animated media strategy did not differ significantly from their female counterparts. Also, Yakubu, (2016), found no significant difference in the academic achievement between male and female students taught Climate Change using Field based teaching strategy. In addition, Usman (2010), opines that outdoor laboratory method enhances academic achievement of students in spite of their gender.

11. CONCLUSION

Based on the findings of this study, the study concluded that Fieldwork Strategy appears to have a strong record of success in enhancing students' academic performance. Students exposed to Fieldwork Strategy performed significantly better than those taught Human Geography by

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

means of Lecture method. In terms of interest, Fieldwork strategy is better than Lecture method. Gender difference exist in the Performance and Interest of students exposed to Fieldwork Strategy. Female students exposed to Fieldwork Strategy performed better than Male students. Teachers at Senior Secondary Schools can explore the potentials of Fieldwork Strategy in order to improves students' Academic Performance and Interest in Human Geography Concepts.

12. RECOMMENDATIONS

Based on the findings of this study, the researcher recommends that:

1. The use of Fieldwork Strategy in teaching geography in school should be encouraged by State Ministries of Education through training of teachers periodically using seminars and workshops to teachers on how to use Fieldwork in teaching with immediate effect.
2. Katsina state ministries of education should ensure adequate monitoring of teachers when using Fieldwork Strategy for improving achievement and interest towards school subjects.
3. The Teacher Training Institutions and professional bodies such as NTI and STAN, to organize a special re-training, workshops, and seminars to geography teachers on how to use fieldwork strategy.

RISKS PERCEPTION OF PUBLIC TRANSPORTATION SYSTEMS DURING PUBLIC HEALTH EMERGENCIES; A CASE STUDY OF PRE- AND POST-COVID-19 ERA IN NIGERIA

Ayomide Samuel Famewo*

Department of Urban and Regional Planning, Faculty of Environmental Design and Management, University of Ibadan, Nigeria

Email: diademsamuel@gmail.com

Kolade Victor Otokiti

Department of Environment and Development, University of Leeds, United Kingdom

ABSTRACT

The paper investigated commuters' trip behavior and risk perception with public transportation during and after the onset of the COVID-19 spread. The study adopted a mixed research design approach, using both qualitative and quantitative data. Quantitative data was acquired through an online and offline cross-sectional survey created through Google forms and printed hard copies, while qualitative data was sought through telephone interviews. The study revealed a change in modal choice from bus/shuttle to non-conventional modes such as motorcycles. More so, the pandemic has unprecedented impacts on sustainable mobility. Therefore the study recommends the development of sustainable mobility futures that can address the impacts of public health emergencies in public transportation in developing countries.

Keywords: Commuters Differentials, Risks Perception, Public Transportation, Transportation Planning, Coronavirus, Post-COVID-19.

1. INTRODUCTION

Globally, the impacts of COVID-19 are still being felt in other sectors of the economy, despite the effective management of its global spread. Regrettably, the COVID-19 pandemic has been adjudged to be the most significant public health challenge of the 21st century (Greenstone & Nigam 2020). In its early days, several studies examined its impacts on essential services such as waste management, health, economy, environment, tourism, and transportation (Kulkani & Anatharama, 2020; Nghiem et al. 2020; Nzediegwu & Chang, 2020; Oyedotun et al., 2020; Moonsammy et al., 2021; Beck & Hensher, 2020; Capital Area Transit Systems, CATS, 2020; CBS, 2020; Wuyts et al., 2020; Committee for the Coordination Statistical Activities, CCSA, 2020).

The enforced mobility restrictions adopted during the pandemic led to the development and utilization of mobility tracking Apps such as Google COVID-19 Community Mobility Reports, Apple Mobility Trends, and Public Transit Index as data-gathering tools and for assessing mobility patterns. For instance, Google provided city scale mobility data (Google COVID-19 mobility 2020), while similar approaches were adopted in studies carried out in Switzerland, Sweden, Britain, and Chile (Molloy et al., WSP, 2020; Department of Transport, 2020; Tirachini, et al., 2020a; Tirachini, et al., 2020b). The main finding from these studies revealed a decline in public transportation, mainly due to mobility restrictions and commuters' risk perceptions.

TeMALab

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Furthermore, studies by Museelwhite et al., (2020) and a report by the Public Health Agency (PHA, 2020) revealed that bus stops and public transport are susceptible for the spread of COVID-19. This is chiefly because of their limited space, availability of large surface areas and challenges with testing commuters and transport operators. Expectedly, these revelations portend danger for sustainable mobility. Studies in England, Scotland, and Wales all revealed a drastic fall for all modes of public transport during the onset of the pandemic and afterward (Department of Transport, 2020). Similarly, the rail system also suffered from the pandemic. For example, in the UK, all franchises changed from privately or publicly owned to management contracts through an Emergency Measures agreement. This led to a continuous fall in rail service and an estimated loss of about £5 billion (Department of Transport, Department of Transport, 2020b; UK Parliament's Public Accounts Committee 2020). According to the Department of Transport (2020), projections, six years of operations are needed before normalcy can be restored in the UK rail sector.

Surprisingly, studies conducted in Australia during the initial phase of the pandemic found that trips by private transport were more adversely affected than public transport (Beck & Hensher, 2020). For instance, trips by personal vehicles were reduced significantly by 47%, while public transport was reduced by 8% (Beck & Hensher, 2020). The decline in private transport might be due to the adoption of work-from-home strategies. In England, during the first phase of the pandemic, there was an upsurge in non-conventional modes such as walking and cycling, both for daily and weekend trips. According to Vickerman (2021), the aviation and maritime sectors were most affected by the pandemic. For example, many flights were canceled, this was largely because of substantial border restrictions (Vickerman, 2021). According to The International Air Transport Association (IATA) an estimated \$84 billion was lost by the aviation sector in 2020 due to the pandemic.

However, these studies were limited on many fronts. First, these studies were either too broad in their scope or relatively too small, using city-scale data made available through data acquired from mobile Apps. Similarly, more recent studies primarily focus on challenges with daily commuting and methods of public transport deliveries (Kamga & Eickemeyer; 2021; Vickerman, 2021). More precisely, most of these studies do not compare commuters' perception of risks of public transportation during or after a public health challenge such as the pandemic but largely focus on mobility trends.

This study uses the Protection Motivation Theory as a theoretical framework. The Protection Motivation theory (Rogers, 1975) emphasized the significance of risk perception in modifying behavior and decisions in cases of uncertainty. Consequently, commuters' perception of a public health challenge such as COVID-19 can influence their transport mode choice and travel demand even after the pandemic has subsided. More precisely, risk perceptions have been found to influence individual and organizational decisions (Sjoberg et al., 2004). It can be assumed that commuters will avoid transport modes with a high probability of contagion of the spread of a virus while adopting transport modes with less probability for spread.

A study by Tan and Ma, (2021) considered commuters' behavior during the COVID-19 pandemic. The study revealed that public and private transportation systems, the nature of the job and walking time from residence to the subway station are factors that increase the risks of infection through the rail system. Consequently, commuters with high-risk perceptions of contracting the virus through public transport were found to stop commuting by rail. However, Tan and Ma (2021) study focused on the rail system, while other modes of public transport such

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

as bus, shuttle, and taxis were not considered. Another study by Basu and Ferreira (2021) examined the challenges and opportunities of Metro-line in post-COVID-19 in Boston. The study revealed that there was an increase in car ownership pre-COVID and Post-COVID-19 and a decrease in public transportation because of the risk perception of commuters. Thus implying an erosion of commuters' trust in public transportation.

Further, Scorrano and Danielis (2021) using an integrated model investigated the mode of transport use before and during the Covid-19 pandemic in an Italian city. Their study reveals an increase in active transportation such as cycling and walking, though insignificant. Also, there is a high substitution between motorcycles and buses. Thus, the pandemic have a negative impact on public transportation and a positive impact on private transport.

Despite, the growing literature on the impacts of the pandemic on public transportation during and Post-COVID. Yet, till date, relatively few studies have compared commuters' risk perceptions and rationality towards public transportation during and after the onset of a public health emergency. Expectedly, the shift in modal choice of commuters for public transportation is a reflection of their risk judgment of being infected. Continuous adoption of private transport will negatively affect sustainable mobility and mass transit initiatives. Therefore, this study sought to explore commuters' risk perceptions and behaviors during and Post COVID-19 in an unorganized public transport system like Nigeria. This will help transport policy experts in Africa and elsewhere to develop measures for promoting sustainable mobility and restoring public confidence in public transport during and after a public health emergency.

2. MATERIALS and METHODS

2.1 Study Area

The study was conducted in Nigeria. Geographically, the country lies between longitude 3⁰ and 14⁰ E and Latitude 4⁰ and 15⁰N. Relatively, it is bounded in the east by the Republic of Cameroon, in the west, by the Republic of Benin and north by the Republics of Chad and Niger, and in the south by the Gulf of Guinea. Nigeria has a coastline of about 420 nautical miles with a network intersecting over 3000 connected rivers and creeks. Inland areas, the country has 900,890 km² and 13,879km². The climatic condition of the country is equatorial, with high temperatures and high rainfall. Administratively, the country is divided into 36 administrative states and with a Federal Capital at Abuja.

Nigeria has a total road network of 204,000km, the largest road network in West Africa and the second largest in the south of the Sahara. The road network consists of 35,000km of federal roads, 39,423km of state roads, and 129,577km² of local government roads. These roads were classified as Trunk A for federal roads, Trunk B for state roads, and Trunk C for local roads; the federal roads accounted for over eighty percent of national vehicular traffic and cut across states and zones in the country (FRSC, 2007).

2.2 Methods

2.2.1 Research design

The study adopted a mixed research design, whereby both qualitative and quantitative data are collected. Qualitative data were gathered through in-depth telephone interviews with twelve respondents across the six geopolitical zones, while quantitative data was collected through an online and offline survey. A semi-structured questionnaire was designed to generate self-

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

reported statements by commuters on their commuting behavior and risk perception to public transportation during and Post-COVID-19. The questionnaire was designed based on the Risk Protection Theory by Rogers (1975) and was revised by transport experts and medical geographers at the University of Ibadan.

The final version of the questionnaire consisted of four sections which included close-ended, semi-open-ended questions, and open-ended questions. The first section contains nine questions, which capture the socio-economic characteristics of commuters. The second section also consists of nine questions, which was adapted from (Roche-Cerasi, et al., 2013) and sought to capture commuters' mode preferences during and Post-COVID-19. In the third section, a total of six questions were used to collect commuters' responses to public health measures enacted to curtail the spread of the COVID-19 after lockdowns. These questions were related to similar instruments developed by in addressing transport risks judgment for road transport (Rundmo, et al., 2011).

2.2.3 Data collection

The online data collection form was created through a Google data collection form. The questionnaire was administered after the relaxation of mobility restrictions and in the early days of the discovery of vaccines. Focal persons were engaged in each region to help populate the research through various links such as WhatsApp, Facebook, emails, and professional contacts. The geographical spread of respondents is shown in Table 1. Critical factors such as adherence to social distancing policies, and challenges with essential services such as electricity, and internet coverage affect the geographical spread of the survey as it was tilted towards certain zones where these services are available.

Table 1. Respondents across the six geopolitical zones in Nigeria

Zones	Respondent	Percent
South-west	244	78.2
South-east	16	5.1
South-south	12	3.9
North-west	4	1.3
North-east	4	1.3
North-central	32	10.2
N	312	100.0

2.2.4 Data analysis

Quantitative data was assessed using descriptive statistics while qualitative data was content analyzed. The questionnaire was completed by 312 respondents. The data collected from the Google form and the hard copies printed were merged and transferred into a spreadsheet. The spreadsheet was downloaded, modified and transferred into the SPSS spreadsheet environment for analysis.

The last section was assessed by developing a Commuters' Risk Perception Index (CRPI). The use of indexes to measure residents' perception of urban services has been affirmed in many studies. Such studies include Afon (Afon, 2006), Center for Public Policy and Social Research (CPPSR 2005), and Opricovic & Tzeng, 2003. This method has been averred to be an extension

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

of the multi-criteria model, where different features of a service rating are generated, weight is assigned to each generated rating, and an index for each is arrived at to produce a rank for each rating that reveals the level of perception (Opricovic & Tzeng, 2003). Thus, adopted in this study. The Commuters Risk Perception dimension was measured using five items, with respondents required to indicate the extent to which each of the items described their risk perception on a five-point Likert scale with ratings from 1 “*strongly disagreed*” and 5 “*strongly agreed*”. The Summated Weight Value SWV for each attribute is obtained by summing the product of the number of responses for each rating to an attribute and its respective weight value.

Express mathematically:

$$SWV = \sum_{i=1}^5 NiVi$$

Where SWV=Summated Weight Value

Ni= number of respondents rating an attribute i

Vi= weight assigned to attribute i

The CRPI for each risk perceived was obtained by dividing the SWV by the summation of the respondents to each of the five ratings. Expressed mathematically as

$$CRPI = SWV / \sum_{i=1}^5 NiVi$$

Where CRPC= Commuters Risks Perception Index

3. RESULTS

3.1 Socio-economic characteristics of sampled respondents

Table 2 presents the socio-economic characteristics of sampled participants. The study revealed that about two-thirds of respondents were male (60.3%). Further, regarding the type of commuters, investigations revealed that more than two-fifths of respondents were employed, and about one-third were self-employed and unemployed respectively. On respondents' level of education, the study found that about 97.4% of respondents had tertiary education. Conducting the survey online might have been responsible for the large responses of educated commuters. It might also imply that the majority of respondents live in urban areas. Assessment of vehicle ownership revealed that a majority of respondents do not own a vehicle. This evidence affirms the need for sustainable public mobility post-COVID which could be negatively impacted by commuters' loss of confidence in public transport due to perception of contagion of a disease/virus.

Table 2. Socio-economic characteristics of sampled respondents

Socio-economic characteristics	Distribution	Respondent	Percent
Sex	Female	124	39.7
	Male	188	60.3

Vehicle ownership	Own a vehicle	28	9.0
	Do not own a	284	91.0
	N	312	100.0

3.2 Trip Pattern Behavior and the Main Impact of COVID-19 on

Table 3 shows the result of trip pattern behavior of respondents during the pandemic and post-COVID-19 era. Trips purpose for work remained relatively unchanged during and after Post-COVID-19. More so, during the pandemic public workers from level thirteen upwards were mandated to continue to commute to work. Hence, always in transit. This result was inconsistent with findings in Australia, which also enforces social distancing measures. There was a fall in trip purposes for work during the pandemic, as workers were encouraged to work from home (Beck & Hensher 2020). In Sweden, social distancing measures were not mandatory but recommended. A study in Sweden revealed a reduction in trips for all purposes during and post-COVID-19 (Jenelius et al., 2020).

For trip purposes for leisure/shopping, there was a sharp increase of 13.4%, on the contrary, trip purposes for health fell sharply by 10.0% between these periods. Similarly, other trip purposes also decreased by 3.5% during these two periods.

In-depth interview discussants reported that the mobility restrictions are largely effective due to the presence of the military and the fear of the virus.

According to a key informant interviewee,

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

“Everyone was afraid when the pandemic first incident case was announced on February 27th, 2020 by the National Center for Disease Control. However, with time and the low numbers of cases recorded, the people began to restore their confidence in public transport. More so, the Federal government is only imitating the procedures adopted by the West without considering the impact of mobility restrictions on an informal economy like ours”

Another respondent commented:

“Well, our government is only saying their own, we still move, just that we have to pay exorbitant fees as drivers have to bribe many of the security officials on the road.” The other nations that enacted hard lockdowns also provide access to food for their citizens, and there are ways food supplies reach every citizen. Our case is different; we have to go out to look for our daily food except you work for the government”.

During the pandemic, the study shows that more than half of respondents took single daily trips while about one-third (24.5%) of respondents took two trips per day. However, post-COVID, slightly more than one-third of respondents took two daily trips, about one-fifth of respondents took single trips, and about one-fifth of respondents took three daily trips. Expectedly, there was a significant reduction in daily commuting post-COVID-19. This might be due to the prevailing economic situation and commuters’ risks perception post-COVID. During the pandemic, the dominant choice of transport was bus/shuttle and Taxi. Although, their share was relatively small. Post-COVID-19, about one-third of respondents adopted a substitutionary approach. They substitute different modes of transport as measures in managing the risks of contagion, while motorcycles there was a significant increase in mode choice for motorcycles and Taxi. Although, the increase is still relatively insignificant. This evidence suggests that commuters change from mass transit mode to non-conventional transport modes such as motorcycles in response to the risk of contracting the virus through public transportation.

Furthermore, the cost of transport during and post-COVID-19 was assessed. Broadly, the result revealed relatively insignificant changes in transportation costs during and after the pandemic. About two-fifths of respondents still spend between one hundred and three hundred naira. However, there was a significant change in trip cost between 301-500 naira, as there was 9.0% increase in price (Table 3).

3.2.2 Main Impact of the Pandemic On Commuters

Table 4 shows the significant impact of the pandemic on commuting during the pandemic era. The study revealed that two-thirds of respondents experienced aggregated impacts, while about one-third of respondents' major impacts were related to an increase in transportation costs. Other negative impacts reported include increased delay time and reduction in social interaction during trips.

Table 4. Major Impact on commuters during the pandemic

Main impact	Respondents	Percent
Increase in transportation cost	100	32.1
Increase in awareness of public health	4	1.3
Increase in delay time	8	2.6
Reduction in social interaction during trips	8	2.6
Aggregated impacts	192	61.4
N	312	100.0

3.3 Commuters' Response to Social Distancing Measures on Public Transportation

Table 5 presents the results of commuters' response to social distancing measures on public transportation. The study revealed that more than half (56.4%) of respondents wear their nose

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

masks whenever they board public transport, about one-third (28.2%) respondents rarely wear nose masks, and 15.4% of respondents do not wear them. Further, on reasons why respondents do not always wear masks whenever they board public transport, about two-thirds (64.7%) of respondents reported that wearing a nose mask is stressful. Responses on whether respondents wash their hands with alcohol-based sanitizer or soaps were documented. More than half of the (53.9%) respondents wash their hands with alcohol-based sanitizer or soaps and running water before and after each trip, about one-third (25.6%) respondents reported that they do not wash their hands before each trip, while about 20.5% respondents do not always wash hands before and after each trip.

Concerning the reasons for not washing their hands, about 63.2% of respondents do not wash their hands because of the failure of operators to provide sanitizers and soaps, while 20.8% of respondents do not wash their hands due to the long queues. The survey sought to know if operators disinfect vehicles before commuters are allowed to come in. A majority (98.7%) of operators do not disinfect their vehicles. Furthermore, the study revealed that a majority (84.6%) of operators' decisions not to disinfect their vehicles do not affect commuters' decision to commute.

3.3.2 Operators Perception on social distance measures Post-COVID-19

Globally, the pandemic resulted into huge loss of revenue for many operators. Many of these operators were forced to implement social distancing measures such as reducing the load capacity of vehicles, providing alcohol-based sanitizer, water, and soaps for commuters, maintaining 1.5m feet apart between commuters, etc. On one hand, a majority of these operators reported that these measures help limit the spread of the virus. On the other hand, they also averred that these measures forced them to operate below their full capacity, which negatively impacted their performance and profitability. According to a discussant on the phone:

“Enforcement of social distancing measures to combat the pandemic in the transport sector is a good one. However, the government in developed countries gives emergency funds and grants to the transport sector to mitigate the reduction in revenue necessitated by the pandemic. On the Nigerian government's part, all the burden falls on the operators and indirectly on the commuters who have to pay for.”

On the sustainability of these measures, most operators affirmed that social distancing measures would die a natural death with vaccines being readily available. More so, operators will return to normal productivity levels. One of the operators confirmed this observation during a telephone conversation,

“The social distancing measures are gradually dying except for the use of nose masks, others such as carrying 60% of the load capacity, washing of hands with soaps/sanitizers and maintaining distance between commuters is gradually phasing out. For daily commuting, the cost of adoption of these measures is telling on the people and operators. Some operators now demand commuters come with their hand sanitizers or any other PPE needed for self-protection. At the same time, the majority operates as if the war against the pandemic has been conquered completely”.

3.4 Commuters’ Risk Perception in Post COVID-19 Era

In this section, a commuters’ risk perception index was developed to measure commuters’ risk perception post-COVID-19. The mean values of the risk index indicate the extent to which commuters’ perceived risk. The result shows that commuters often cover their nose with nose masks and use sanitizers to reduce the risk of contracting COVID-19 ($x=3.72$), reduction in the frequency of visits to public places ($x=3.51$) are measures highly practiced by commuters in responding to risk, while the likelihood of changing modal choice as a result of the pandemic ($x=2.88$), taking more walks or cycling($x=2.83$) and decrease in the frequency of trips($x=2.81$) are poorly practiced. Nigeria operates a highly informal economy where the livelihoods of residents depend on their daily commuting. Thus, the choice of commuters to keep commuting and adopting social distance measures such as using nose masks, reducing trips to public recreation places, then reducing trips for work or health. While commuting via cycling and

walking is more beneficial, it was observed that it was rarely adopted. This is because these modes have not been integrated into the Nigerian transport system and are also part of the Nigerian commuting culture. Hence commuters do not respond positively to changes of modal choice and adoption of cycling and walking.

Table 6: Commuters Risks Perception Index (n=312)

Variables	Minimum	Maximum	Mean	Rank	(A-μ)	(A-μ) ²
Would you decrease the frequency of trips based on fears of exposure to the pandemic	1.00	5.00	2.81	5 th	-0.34	0.1156
Are you likely to change your modal choice as a result of the pandemic	1.00	5.00	2.88	3 rd	-0.27	0.0729
Do you take more walks or cycle to reduce exposure to the virus	1.00	5.00	2.83	4 th	-0.32	0.1024
Do you always cover your nose with nose masks and use sanitizers to reduce pandemic contact	1.00	5.00	3.72	1 st	0.57	0.3249
Did you reduce your frequency of visiting public recreation places (eateries, Cafes, movie theaters) even as lockdown measures were relaxed	1.00	5.00	3.51	2 nd	0.36	0.1296

4. DISCUSSION

In this study, the majority of respondents were employed and did not own a vehicle. Thus, many of these respondents will depend on public transportation systems. The study revealed no significant change in trip purposes for work during and after the mobility restrictions compared to other trip purposes. In Nigeria and elsewhere in Africa, public transportation systems are often characterized by resource imbalance, infrastructural deficit, variation in objectives by operators and policymakers, and weak intermodal linkages. Hence, the impacts of the social distancing measures such as mobility restrictions will exacerbate the chaotic transport network in the face of a public health emergency such as Post-COVID-19.

One main finding of this study is the change in modal choice from bus/shuttle to non-conventional modes such as motorcycles and Taxis. This might be due to the fear of contracting the virus through buses/shuttles. These fears are justifiable as studies by Museelwhite et al. (2020) and PHA (2020) confirmed that public transport modes such as buses and shuttles are more susceptible to spreading the virus. However, Famewo et al., (2020) suggested that active transportation modes such as motorcycles should only be limited to intra-city and campus transportation systems and not city transportation systems as they portend greater danger for commuters in the city.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

The findings suggested that Nigerian commuters will adopt social distancing measures that are compatible with maintaining daily commuting while they will reject measures that will enforce mobility restrictions during any public health emergency. Their choices are largely due to the high level of informality, the poor level of the public transport system, and the failure of the government and its agencies to mitigate the economic impact of public health emergencies. Consequently, it might be difficult to envision and realize sustainable mobility in a system that has a pervasive transport system as it is the case of Nigeria. More so, it will be difficult to gain public confidence during and after such public health emergencies in such climes.

Finally, the study developed a commuters' risk perception index to measure and rank commuters' risk to public transportation in Post COVID-19 era. The study revealed that commuters highly adopt the use of nose masks and sanitizers in responding to the pandemic, while commuters' reduction in the frequency of trips was poorly practiced.

5. CONCLUSION

This study documents commuters' behavior and risk perception towards the public transportation system during and post-COVID-era in Nigeria. Moreover, lack of planning, shortage of transport infrastructure, environmental impacts of transportation, traffic demand, accessibility, inter-modal linkages, and affordability still characterize public transport in Nigeria and elsewhere in Africa. A chaotic public transportation system will limit individual and organizational decisions toward promoting sustainable mobility during any public health emergencies. Expectedly, commuters' risk judgment will affect public transportation and modal choice in public health emergencies. Hence, there is a need for holistic measures in the quest for sustainable mobility and mass transit that can lead to public health emergencies.

We suggest the need to transition to sustainable mobility that would be based on an urban plan that considers investment in modern transport infrastructure, an integrated transport system that integrates different land uses, and transport modes, and has respect for the socio-cultural context of commuters.

6. STUDY LIMITATIONS

This study comes with several limitations. First, by adopting a cross-sectional study, the study suffers from the inherent limitations that come with such a survey-based research method. This can be addressed in the future through longitudinal studies. Also, the use of telephone interviews to capture qualitative data might limit the validation of the submission of the interviewees, as body language could not be captured. However, these methods give commuters and operators the flexibility to express themselves without much interference. Also, the initial use of an online survey which was later supported with printed hard copies might have limited responses from respondents who live in rural areas or areas without internet access. However, none of these limitations have a strong influence to affect reported responses.

Ethical Approval

The nature of the research was not done with animals, vulnerable groups, or in an invasive manner. The research was done in complete confidentiality with voluntary participants.

Funding

These authors declare that no funds, grants, or other support were received during the preparation of this manuscript.

ABSTRACT

Cities around the world are becoming smarter with the use of innovative technologies. The applications of the Internet of Things (IoT) in some cities have immensely influenced communication, transportation and policy efficiency, promote sustainability, reduce waste and inconvenience and ultimately increased economic and social service quality in such cities. A smart city is predominantly composed of the use of advanced connectivity of devices, systems and services to develop and promote sustainable practices in order to improve operational efficiency and provide better quality of life. IoT is mostly used for the automation of appliances such as wearables and scannable devices including waste bins, vehicles, bridges, etc., and the control of lighting, heating and ventilation systems. Hollands (2008) defined a smart city as the one that allows the application of innovative technologies to its various components including governance, transport, housing, business, sustainable living, social learning, community engagement, etc., with the aim of creating better living experiences for the city's population. This paper is a document review on Internet of Things (IoT) based intelligence on smart city system architecture. The paper described various IOT based components of a smart city. Also discussed in the paper write-up are some of the challenges of Internet of Things (IoT) deployment for of a smart city. In order to gather relevant information for the paper discussion, online Google form questionnaire instrument was used to collect data from respondents. The responses collated were subjected to reliability analysis by experts. Conclusively, recommendations were made.

Keyword: Internet of Things, IOT Based Intelligence, Smart City, Architecture.

1. INTRODUCTION

Smart Cities are governmental initiatives for making cities more navigable and adaptable to the increasingly growing population of city dwellers to enhance better living experience in areas such as communication, transportation and policy efficiency so as to promote sustainability, reduce waste and inconvenience and ultimately increased economic and social service quality in profound ways. Internet of Things (IoT) which refers to the automation of appliances such as wearables and scannable devices including waste bins, vehicles, bridges, etc., and the control of lighting, heating and ventilation systems through internet connectivity has helped to make life better in the various sectors of cities including

governance, transport, housing, business, sustainable living, social learning, community engagement and many more. This paper provides a document review of IoT based intelligence on smart city system architecture and discuss described various IOT based components of a smart city. Some of the challenges of Internet of Things (IoT) deployment in smart cities were also discussed in the paper.

2. RELATED LITERATURE

Hollands (2008) sees smart cities as the use of the evoking technologies to create a better living experience for city dwellers. According to Rojek & Studzinski (2019), Smart city services that involve municipal tasks including waste management, supply of water, monitoring and environmental control are targeted towards the sustenance of the city's population. Benjamin et al. (2015) posit that the possibility of connecting identifiable objects in smart cities is on the high side. Ejaz & Anpalagan (2019) explained the architecture and applications of IoT in Smart Cities and the various technologies used. Somayya (1991) discussed the numerous applications IoT in Smart Cities as becoming popular across many vertical and horizontal markets. Silva, et al (2018) explained the applications of some systems used in various sectors of smart cities. According to Dutta, et al. (2017) and Al-Turjman & Malekloo (2019), sensors are used in smart cities to monitor environmental conditions so as to determine the pollution level and also guide citizens to free parking space so as to save cost. Despite the benefits of using IoT in Smart cities, it is also confronted with a number of challenges (Rolf, 2010).

Components of IoT Based Smart Cities

1. Smart Home:

This is essentially a major component of Smart Cities since it directly related to the life of city's dwellers. This involves the use of sensors that provide information to monitor the users' activities within and around their homes.

2. Smart infrastructure:

Smart infrastructure such bridges, roads and buildings equipped with sensors are paramount for predictive maintenance of operations of the listed components of the city.

3. Smart City Services:

Smart city services such as water, waste and environmental control are

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

equipped with sensors for adequate update to ensure proper management.

4. Smart Energy:

Smart Grids make use of ICT technologies to ensure regular updates on the distributed energy generation at both the consumer end and utility end and it also equipped with self-healing capabilities.

5. Smart Transportation:

The development and implementation of innovative technologies have made the design of smart transportation systems possible. GPS devices help to generate data which are used to track traffic patterns and driver behavior.

Challenges in IoT Based Smart Cities

Besides the benefits of digitization of every domain of a city's operation mechanism, the deployment of IoT systems carries several challenges that need to be considered. Viz:-

1. Security and Privacy:

The primary concern in smart cities is security and privacy issues. Because essential city infrastructures are online, the aberration of any of the operations will bring inconvenience to the city dwellers thereby putting lives and properties at risk.

2. Networking

IoT depends on the capability of sensors and the interconnectivity of all identifiable devices in order to send and receive information among themselves and the Cloud. Ensuring effective networks for these devices to remain connected is a big concern.

3. Smart Sensors:

Smart sensors are manufactured by host of numerous vendors with enormous sensing mechanisms, data formats, standards of measurement and connectivity protocols. The operation involved in the deployment required by Smart cities for all these devices to perform tasks scheduling between them, exchange data and aggregate these data together for making inferences are complicated.

4. Big Data Analytics

The growing rate of data generated by IoT connected devices are on a daily increase. In order to make use of this data and constantly improve on the services delivered in smart cities, there is a need to develop new data analytics algorithms. This poses a big challenge.

3. MATERIALS and METHODS

This paper discussion is focused on Internet of Things (IOT) based components of a smart city. The accessible populations for the study were states in randomly selected developed countries around the world. For the purpose of eliciting useful

information for the paper discussion, carefully structured copies of questionnaires were administered to respondents using online Google form questionnaire instrument. The gathered responses were subjected to Cronbach's alpha reliability analysis. The result of 0.87 gave a good reliability index of the instrument. The entire exercise took place within the duration of 41 days before completion.

4. RESULTS and DISCUSSION

Fig.1: Chat Analysis

The graph plotted in Figure 1 indicates that most of the respondents are knowledgeable of smart city concepts. The respondents precisely noted that smart cities use IoT devices such as connected sensors, lights, and meters to collect and analyze data. The respondents further explain that smart cities resultantly use the data gathered by IoT-enabled devices from various parameters to improve public utilities, social infrastructure and services provided for the city dwellers.

Fig.2: Chat Analysis

The chat analysis shown in Figure 2 depicts that the influence of Internet of Things (IoT) on the development of smart cities cannot be undermined. The respondents noted IoT has paved the way for developing smarter and more sustainable cities. According to the respondents, IoT technologies are increasingly revolutionizing the way people live and interact with each other in the city from enhancing public safety and citizen engagement to optimizing energy consumption and transportation.

Fig.3: Chat Analysis

The graph plotted in Figure 3 suggests that a very high number of the respondents agree with the statement that there are better days ahead of IoT influenced smart cities. According to the respondents, it is anticipated that the global IoT trends in the smart cities market will grow significantly. The respondents also noted that one of the key benefits of IoT in smart cities is improved traffic management. In addition, the respondents opine that the deployment of IoT technologies in cities could be useful in monitoring and managing traffic in real-time which will resultantly help to improve safety, reduce congestion and enhance overall transportation efficiency.

Fig.4: Chat Analysis

The graph plotted in Figure 4 indicate that a greater number of the respondents agree that that are obstacles or challenges confronting the implementation of Internet of thing (IoT) based intelligence on smart city architecture. According to the respondents, the key element of these challenges include: the problems with interoperability, security and privacy concerns and vulnerability to malicious activities by hackers because most of the objects connectivity are enabled through RFID.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Fig.5: Chat Analysis

The table plotted in Figure 5 shows that a significant number of the respondents rated the influence of Internet of Things (IoT) on smart cities architecture as being 'Effective'. The respondents explain that IoT has unlimited potential. According to the respondents, the deployment of IoT technologies into urban hubs could help to transform it into sustainable, efficient and smart cities.

5. CONCLUSION

This paper write-up is a contextual review on IOT based components of smart cities. Various IOT based components of smart cities were described in the paper work. Also contained in the paper discussion are some of the challenges confronted by the deployment of Internet of Things (IoT) based smart city architecture. The paper noted that Smart Cities are initiatives aimed at making city dwellers to experience better standards of living experience and to enjoy the innumerable social service offered by its government.

6. RECOMMENDATION

The concept of Internet of Things (IoT) based intelligence on smart city architecture is essentially critically important. Based on the current research on this paper, it was noted that most of the data transfer standards developed for IoT are not compatible as of the time this paper research work, it is therefore recommended that further research work should be carried out in this area to ensure effective communication among sensor nodes while utilizing low power using different protocols; this is imperative to improve on the intercommunication between IoT devices and invariably make the components of a smart city architecture smarter.

ABSTRACT

The necessity of sustainable urban cities was observed throughout a survey in 2008 when the survey saw that more than half of humanity was living in urban areas in the world. An estimated 1900 urban areas account for 13% of the global population. The U.N. has estimated that by 2030, total urban areas will host 60% of the worldwide population. It is a significant concept of global change along with rapid changes in Africa and some parts of Asia. Urban areas are home to more than 470 million people in Africa, which accounts for an estimated 40 % of the total African population from an estimated 14 % of the population in the middle of the 20th century. In 2016, an estimated 512 cities hosted at least 1 million inhabitants, of which more than 100 cities were in China. By 2030, it has set up an estimated 660 cities, with around 40 cities categorized as megacities home to more than 10 million inhabitants, including Bogota, Bangkok, and Ho Chi Minh City. Cities have faced many challenges, including housing, sanitation, transportation, energy problems, etc. Also, issues have arisen in those developing and emerging countries due to weak institutions, poor resolution or no resolution processes, effects of climate change, waves of migration problems, etc. Therefore, a necessity has been created to explore sustainable, dynamic, healthy, and safe cities, which will be recognized as intelligent and ecological cities as a global change process. As a process of making smart cities building innovation through using tools like building information modelling (BIM), which is like 3D-modelling software with layers of data on every detail along with project timeline; evolution of internet system for overall information; linking houses, public buildings, factories vehicles, power sanitation, traffic signals, and street lighting etc. that makes a city 'smart.' Economic concern through promoting economic efficiency for creating more jobs and social inclusion are those things that can build a town dynamic and sustainable. The paper aims to discuss intelligent cities of the world as a concept of global changes through various sustainable facilities, including creating a green environment in ecology. The methodology has been conducted through documentary analysis. The feature question is, what are those challenges for building smart cities in developing countries, and why are smart cities required as a process of the sustainable world?

Keywords: Smart City, Eco-friendly, Ecological City, Global Change, Environmental Balanced, Technology, Infrastructure, Global Cities, Urbanization,

1. INTRODUCTION

A smart city has been defined by its urban planning, governance, transportation, technologies, environment, and health care system (World Economic Forum, 2021). The smart city always has many combinations of technologies, such as mobile solution, big data, artificial intelligence, blockchain, etc., through which they operate many concerns and addresses issues, such as data privacy and social exclusion. Smart city has been categorized by many globalized

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

organizations, such as the World Bank's global smart city' partnership program, which has been defined through a virtual knowledge exchange program on smart cities for sustainable development (World Economic Forum, 2021). Many participants joined in this context to determine the smart city. Many terms emerged from the discussions, such as technology, innovation, connection, etc. The most valuable term was connection.' Participants finalized that smart cities can be made through community connections through awareness and collaboration. Realization and understanding to become clean in the city is another way they mentioned to maintain a smart city. Therefore, a clear definition can be made throughout the discussion that a smart city combines sustainability and resilience through which the city can be looked at urbanely. One of the examples has been given by the Chief Technology Officer of the City of Barcelona; as one of the global smart cities, the term' data and technology' over a smart city has been changed, and the term' citizens intelligence.' A common perspective about data and technology has been slightly altered to define smart cities, and many terms are included on the other side, such as the term humanizing technology. (World Economic Forum, 2021). It is a concept through which citizen of the cities have been involved to directly help the city management by suggesting ideas about smart city definitions and their implementation. Therefore, the City of Barcelona, as a model example, has already implemented a connection between its citizens, who are experienced in many disciplines, with city management to make better decisions, according to the Chief Technology Officer of Barcelona (World Economic Forum, 2021).

The role of the private sector in smart cities has been changed from selling widgets to promoting an outcome-driven model. A model like a stronger partnership has been accepted widely for helping urban leaders achieve their goals. Many private sector, civil society and academia come together to build a cooperative industry to develop the cities for proper living. Many models can be exemplified for good urbanization, such as Smart City Challenges by Infrastructured Canada, City Possible by Master Card, the Helsinki Energy Challenge, etc. (World Economic Forum, 2021). According to the Professor of the University of Pittsburgh, Mertin Weiss, the impact of COVID-19 has changed the views of policymakers globally, and newly intelligent city development has been categorized in every country for a sustainable environment through which citizens can live a healthy and better life by protecting them from such future virus. According to the professor and adviser, a system should be categorized as high-speed services instead of heavy infrastructure investment. The impact of COVID-19 has changed the views on mobility in cities. The Coordinator of the Chilean Transportation System, Pedro Vidal, said they had explored various ideas and implemented them in Chilean cities for mobilization through the connection with universities for advice. One of their innovations is creating more awareness to ride bicycles for city mobilization. Therefore, they made lanes on the road for bikes. This is how more sustainable cities have been categorized in Chile (World Economic Forum, 2021). According to the Deputy Director at the Open Government Partnership (OGP) Rudi Borrman, openness and transparency are essential for gathering data for public services. It was an effective route throughout open collaboration during the pandemic. According to her, a smart city can be defined when local governments create and innovate ways to coordinate and collaborate transparency with stakeholders. She says that this openness must be made on trust to bring solutions for the citizens by using technology. Therefore, the intelligent city definition depends on using technologies through an open engagement with citizens and local urban governance for better deeds. In the post-pandemic era, focus needs to be prioritized on equalities through which poor cities in poor developing countries can make their sustainable

September 14-15, 2023, Naples, Italy

infrastructure for the better living of their citizens. Digital rights for every citizen, as well as data privacy, must be protected to build an intelligent urban community by technology and creating a protective environment (World Economic Forum, 2021).

2. LITERATURE REVIEW

Every developed or developing country dreams of making smart cities. But it is not that easy to make a smart city as it has many definitions that have been given above. A smart city is environmentally spread surrounding, green, clean, and sanitized, such as Edmonton, Alberta, Canada. Unfortunately, many developing countries' infrastructure is chaotic due to environmental, economic, and social disorders. Therefore, climatic problems arise and pollute urbanized areas through hot temperatures, acid rain, unmanageable humidity, etc. Indeed, a person from a cold country such as Canada can not afford the chaotic environmental features in those developing countries. Therefore, they cannot live sustainably for a long time and return to Canada with many health problems such as headaches, stomach problems through indigestion, etc. These are all due to the issues of the environmental, social, and economic features of the smart city characteristics of those developing countries. In this context, a general overview has been focused on practical experience by travelling to developing countries from Canada. Therefore, cities of developing countries must be environmentally friendly for a sustainable environment where citizens and travellers from any climatic characterized countries can live nicely and gently. In this context, plantation in cities for greenness is an important task to reform those cities for the recognition of smart cities. Urbanization must be built based on city law, and the law must be made on city structure where houses are made with enough space for sustainable activity such as plantation in yards of every home, making more parks for a more relaxed environment. Rain thus creates the influence of a green climate during the summer when it is uncontrollable. It is, therefore, a climatic chain which can be made by becoming eco-friendly in urban areas globally. In terms of technologies, smart cities must have a foundation of information technology (Beevor, 2018). Information technology can be invented by launching a speed internet system in urbanized areas and making more tools and machines by creating artificial intelligence. A balance is needed to develop smart cities, which can be possible by collaborating or combining public organizations, state and local governments and private enterprises. This is how a smart city can be created with facilities for business sustainability, disaster prevention, public safety, and life improvements. The smart city ecosystem and its I.T. infrastructure (Beevor, 2018) must be agile and flexible for all. Innovative city data processing must be effective, efficient, and analytical in real time. Otherwise, things are irrelevant for the making of smart cities. Recently, many citizens died (an estimated 4,000) in Libya through floods and other natural calamities. Their dead bodies were falling on the roadsides in the entire city because of the poor infrastructure of the Libyan cities, such as the absence of disaster management, warning satellites, lack of dams and bridges to tackle water from the rivers and seas and poor city sanitation to tackle floods from many sources (Ahramonline, 2023). The world's Smart cities must focus on that infrastructure system to protect their citizens from natural calamities. There is a governmental problem with making smart cities due to political differences and their views. It is a political challenge. The challenge can create the issue of funding due to ideological differences in making smart cities. There is another backdrop of challenge in making smart cities, which is private and public thinking differences and a lack of coordination. They must be cross collaborated for needing to know

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

data sharing policy, standard network tools and other infrastructure. Therefore, an environment must be built for building digital infrastructure to support intelligence-led policing.

3. METHODOLOGY

The paper has been assumed through subordinate sources of data. Subordinate sources of data include academic articles, websites, etc. The description of sources has taken the method of writing the essay, reading, gathering in-depth insights on topics, exploring ideas, summarizing, interpreting, and mainly expressing in words (documentary analysis through qualitative approach). This paper has discussed many criteria of innovative city development through building social bonds and collaboration between authorities, building infrastructure by mentioning renowned professionals' recommendations and countries' disasters like Libya. This paper has given importance to ecology towards building smart cities, its digitalization and information technology systems for a better amalgamation between citizens and governance. It has discussed challenges and sincerely addressed the definition and structure of smart cities, a discussion of global cities, and an evaluation.

4. DISCUSSION

According to Navigant Research competent city evaluation has been made based on smart energy, smart water, smart transportation, smart buildings, smart government sectors and regional segmentation (Paul, 2017). City leaders and the federal government are now realizing the benefits of smart city development. Therefore, collaborations have been made with private industries and other stakeholders for economic benefits, sustainability, and quality of life. According to the Navigant research (Paul, 2017), an estimated 250 smart city projects from 178 countries worldwide have been initiated by the collaboration of governments and private organizations to fulfill energy, transportation, buildings, government solidarity and water goals. According to the research analyst of Navigant Research, Christina Jung, Leading cities are looking at how they can build on their initial investment in open data and the data feeds being provided by Internet of Things applications. Nowadays, due to the improvement of sensor technology, technologies of smart cities have been more developed and efficient for higher performance than before, according to the research group's report. Therefore, it is an expectation from the information that smart city solutions will grow from an estimated \$40.1 billion in 2017 to an estimated 97.9 billion in 2026 (Paul, 2017). Building smart cities has been prioritized because of the rapid increase in global population and their existence in cities. It has been reported that global cities now account for more than half of the worldwide population, which is an estimated 68%, according to the United Nations (Kosowatz, 2020). Therefore, a question has been raised: How will the management protect and maintain the city population due to the rapid increase of urbanization worldwide? It has been said that technology is once again a key which has always been a significant narrative during the discussion of smart city development for urbanization. Action has been initiated by leveraging technologies for the evolving smart city development program. For the demand of urban residents' policy, policymakers from the local and federal governments and urban planners have laid the foundation for leveraging technologies (Kosowatz, 2020). It has been initiated for better distribution of services among the residential communities in the urban areas. Those projects are in the infancy stage as most of the projects are in the background of a 'smart foundation.' After about ten years, a digital solution' has been created for the deliberation of real-time information to the users and providers through connected applications. Therefore, a definition of a smart city has been completed, which has been analyzed before that a smart

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

city will be a combination of technical and mechanical solutions, which are intelligence IOT solutions for optimizing infrastructure and governance for better involvement with urban citizens in the management of services. Mobility, healthcare, security, water, energy community engagement, housing, economic development, and waste management are critical factors in creating a smart city and its innovation. There is a three-layer concept for the operation of a smart city. The first layer is technology, which is smartphones and sensors connected by high-speed communication networks, according to a scholar, McKinsey. According to McKinsey, the second layer is a specific application that translates the stream of raw data into alerts, insight, and action, and the third layer is getting buy-in and involvement with the public and participation from the crowd. Real-time crime mapping helps in policing, a connection between practitioners and patients through telemedicine that allows practitioners to arrive at patients' homes, digital tracking of waste receptacles which can predict garbage hauler when a can is full, online connection platforms for fast-speed internet access etc. are all narratives for innovative city-building initiatives. Many cities are providing those technologies for a digital and sustained urban livelihood.

The southeast Asian city-state of Singapore is the second most densely populated city in the world, with an estimated 8000 people per square kilometre. Facing such population growth and an aging population (Kosowatz, 2020), the government has prioritized a digital revolution to increase productivity in an advanced country. Therefore, the 'Smart Nation Vision' (Kosowatz, 2020) of Singapore aims to digitally collect information around the city by linking sensors to aggregation boxes. An estimated 95% of city homes have broadband access, and open sourcing brings the information to citizens and the private sectors to leverage the data for personal and business uses. The National Research Foundation has aimed to build Singapore as a digitized city on a 3D city model and collaborative data platform. By 2022, the government of Singapore has sought to implement intelligent and energy-efficient lighting for all public roads and solar panels installed on the rooftops of an estimated 6,000 buildings in Singapore City.

The Government of Emirates has decided to install all governmental services in Dubai City through a hyperloop (Kosowatz, 2020). Those services are transportation of Dubai, communications, electricity, infrastructure, economic assistance, and urban planning. An estimated 90% of services are now digitalized and accessible through the 'Dubai Now' app. Dubai is using high-tech projects by using innovative technology to build a 31-foot-tall 6889-square-foot concrete building. Dubai-Abu-Dhabi hyperloop is perhaps the best-known project; an estimated 151-kilometre-long and 10-kilometre section has been completed. Oslo, Norway, has been featured as a global smart city. The city has always focused on climate change issues, placing it one of the best-known livable urbanized cities in the world. Oslo comprises a wide use of sensors for controlling the city's lighting, heating, and cooling (Kosowatz, 2020). The city has set a goal to cut emissions by an estimated 36% by 2020 and an estimated 95% by 2030 for more technological development, electric vehicles, charging technology, and a smart grid. There are an estimated 2,000 charging vehicle stations. The owners of the cars do not need to pay taxes, and they are entitled to free parking, charging and transport on ferries.

Norway has already announced building a smart city near Oslo airport to create a new technologically driven community. Copenhagen, the capital of Denmark, is known for aggressive environmental policies to sustain the city's eco-friendliness. In 2017, the incubator Copenhagen Solution Lab was awarded for monitoring traffic, air quality, waste management and energy use for real-time operation. It connects traffic systems, parks, buildings, smart

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

metering, and charging systems for electric vehicles to direct the traffic in the real-time process. Half of the Copenhagen residents, including their Prime Minister, bike to work (Financial express, 2018). The city of Boston, in the United States, was one of the first global cities to initiate a smart urban city concept. Its 'participatory urbanism' (Kosowatz, 2020) is one of the best smart city initiatives in the world for citizens' participation for advice and suggestions throughout their lifelong experience in many professional fields. Participatory Chinatown is a videogame for the involvement of communities in the planning and development of Boston. Traffic roars of Boston are famous for various mobilities. A micro hub, therefore, is created to control real-time information, buses, trains, bike-shares, car-shares, and other city services. Amsterdam, the Netherlands, has created an estimated 12,000 datasets and technology in every urban district (Kosowatz, 2020). Public and private collaboration has helped to build a smart grid in housing development, where power is distributed and stored on demand. The city has also generated electricity from carbon dioxide. Pedestrians and cyclists can use apps to increase their lights when passing by. New York City, the United States, placed hundreds of smart sensors and low-powered area networks throughout several districts. It will monitor and manage trash pickup waste containers fitted with sensors and monitor when the cans are full. New York police have tested web-based software from Hunch Lab to use historical crime data and other information to predict and respond to crime (Kosowatz, 2020). It helped to decrease crime in the city and helped to increase interest rates among other city agencies. Connected London through 5G connectivity for the entire city is one of London's major smart city programs.

The Mayor of London has started a platform for the development of urban areas and thus solves many issues. The city makes public data as much as possible for the citizens and campaigns many things to encourage the citizens to participate in discussions with the government. London's iconic lampposts are fitted with sensors and charging points for electric devices (Kosowatz, 2020).

The city of Barcelona, Spain, is famous for the constant innovation of technologies to maintain Barcelona as one of the best global cities. In 2011, Barcelona hosted the first 'Smart City Expo (Kosowatz, 2020) and 'World Congress for the promotion of a 'self-sufficient city' (Kosowatz, 2020) of productive citizens and its suburban neighbourhoods at human speed throughout a hyper-connected zero emission megacity area.

Hong Kong, China, pushed a major change to reform the city as a smart city in 2019. More than 70 initiatives have been launched to cover the city of Hong Kong, called 'smart government for smart economy.' City lampposts were fitted with sensors. The city has aimed to make them a 5G development. The 55-kilometer-long Hong Kong and Macao bridge is an outstanding example of connection and communication, one of the best features of smart city development (Kosowatz, 2020). One of the attractive initiatives of Hong Kong is a mobile-friendly city dashboard screen. The dashboard screen uses data from various government sources to show real-time images, maps, icons, and other information about the city.

5. CONCLUSION

The feature question is, what are the challenges for building smart cities in developing countries, and why are smart cities required as a process of the sustainable world? Building smart cities in developing countries needs infrastructure technology. One of the technologies is a sensor which collects data on everything from rush hour stats to crime rates to overall air quality for the maintenance of sensors. A Complicated and costly infrastructure is needed to

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

maintain those sensors, which is very hard for production and utilization in developing countries. They lack the technologies to create such sensors and the techniques to keep them. Major metropolitan cities (Stone, 2018) in developing countries face reform problems because of their old infrastructure, such as transportation tunnels underground wiring steam pipes, to introduce a high-speed internet system. Security and hackers are another challenge for the smart city development program, especially when they hack information from sensors and shut down an entire city.

This is a big challenge in a smart city development program. Developing countries are out of those highly moderated technologies to protect their smart city from hackers. For a secured sensor program for the protection of information, developed countries are capitalizing hugely, which is possible due to high industrialization and economic solidarity.

Developing countries can not invest a lot of finance to secure smart city development programs. A smart city is even a dream for developing countries due to its lack of technological exploration, innovation, and financial maintenance. Education and Engagement (Stone, 2018) is another challenge in developing countries.

In developed countries, it is an inspiration throughout the launching of many governmental campaigns for the involvement of citizens in governmental activities. It is challenging in developing countries due to a lack of education and involvement initiatives. Citizens of developing countries are fighting poverty. It is, therefore, very hard for them to engage with the government to discuss a smart city development program. It could be a dream for them.

Social inclusion (Stone, 2018) is another issue in developing countries, which is almost nil in those countries due to a lack of collaboration between private initiatives, a lack of education and awareness among citizens and ignorance from all. Smart cities are essential and required for the globalized world for economic benefit, social inclusion, cultural innovation, and educational awareness.

Post-pandemic world demands for smart cities more than before due to a protective environment for the global citizens and the citizens of its urbanized areas. Therefore, more technological exploration and innovation are needed to create smart cities. In this context, the developed world must help developing countries build infrastructure and social inclusion through better education, awareness, and the distribution of health and well-being among citizens of developing countries.

Smart cities of developing countries can be a successful inclusion when developed and developing countries work together to create a better universe. There should not be any inequalities for a better livelihood among the citizens of both developed and developing countries.

Developed countries like Canada can help many developing countries with urbanization and infrastructure innovation. Edmonton has proved itself a major Canadian city, a world leader in leveraging technology and innovation to distribute an equal, exceptional life for its citizens. The city has a vast ecosystem for a friendly environment. It has an encouraging healthcare system, a carbon-neutral community, and many smart city development themes to encourage city people.

The City of Edmonton Council is a significant hub for the participation of citizens with the municipality as well as the provincial government. For this initiative, the City of Edmonton

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

received the 'Gold Prize in the Open City Category of the We Go Smart Sustainable City Awards,' which promotes outstanding information and communication technology, smart city innovation plans and e-government. Therefore, it is hopeful that Canada is a humanitarian country with a tremendous record of helping poor and developing countries build smart cities for sustainable living.

ABSTRACT

Aim of the research was to study the key issue aspects, characteristics and effects of antioxidants in miscellaneous immunotherapeutic directions. Oxidation is a natural process. However, it can cause chain reactions that damage human cells. Antioxidants capture and release free radicals from the body and control lipid levels (especially cholesterol) in the blood. It has anti-cancer effect, stops the growth of cancer cells, and can also inhibit cancer cells. Stimulates and simultaneously activates the regeneration of normal and healthy cells. Supports normal platelet function and reduces blood viscosity. Provides free blood circulation in the vessels and promotes the elasticity of the vessels. Antioxidants have anti-inflammatory and antibacterial properties. Antioxidants keep the skin fair and supple and prevent premature aging. It has the ability to restore and regulate the growth of collagen fibers, restore youthfulness to the skin, anti-allergic by neutralizing the release of histamine, improve memory, increase the body's resistance to stress, and lower blood sugar levels. Vitamins, minerals, and enzymes called antioxidants can prevent these reactions. Antioxidants are considered an important part of a healthy diet that supports body systems, including connective tissue, respiratory, digestive, and cardiovascular systems. The best way to avoid deficiency is to get your daily dose of antioxidants from healthy plant foods like fruits and vegetables. However, you may need supplements to compensate for occasional oxidative stress (especially in elite athletes) or nutritional deficiencies. High levels of free

radicals are the starting point for many diseases, from the common cough to cancer. Violations appear in the body, inflammatory processes develop, atherosclerosis develops, the digestive system is disturbed, malignant tumors, heart disease, etc. appear. The human immune system plays an important role in the fight against free radicals. The appearance of signs of aging is associated with a decrease in immunity and the action of free radicals: weakness in the muscles and skeleton, loss of skin elasticity, decreased functioning of the senses - hearing and vision, as well as problems and various mental processes. Propolis and flavonoids have been shown to inhibit IL-10, IL-4 and IL-13. IL-4 and IL-10 inhibit IL-12 induced IFN- γ secretion. In addition, IL-10 counteracts many of the pro-inflammatory effects of TNF- α and IL-1 β , while IFN- γ can inhibit monocyte production of IL-4 and IL-10.

Keywords: Characteristics, Effects, Antioxidants, Immunotherapeutic, Treatment, Directions.

1. INTRODUCTION

Reactive oxygen species (ROS) are produced by living organisms as a result of normal cellular metabolism. At low to moderate concentrations, they are involved in normal cellular processes, but at high concentrations, they cause harmful changes in cellular components such as lipids, proteins, and DNA. The shift in the balance of oxidants/antioxidants in favour of oxidants is called oxidative stress. Oxidative stress contributes to the development of many pathological conditions, including cancer, neurodegenerative diseases, atherosclerosis, hypertension, ischemia/reperfusion, diabetes, acute respiratory distress syndrome, idiopathic pulmonary fibrosis, COPD, and asthma. Aerobic organisms have built-in antioxidant systems, including enzymatic and non-enzymatic antioxidants, which are generally effective in preventing the harmful effects of ROS. However, under pathological conditions, antioxidant systems can be overloaded. In this review, we summarize the cellular mechanisms of oxidants and antioxidants, as well as redox and redox regulation in health and disease [1-3].

ROS are formed from molecular oxygen as a result of normal cellular metabolism. ROS can be divided into 2 groups: free radicals and non-radicals. Molecules that contain one or more unpaired electrons that make the molecule reactive are called free radicals. When 2 free radicals share their unpaired electrons, a non-radical is formed. The three main ROS of physiological importance is superoxide anion (O₂⁻), hydroxyl radical (-OH), and hydrogen peroxide (H₂O₂) [4-5].

Other oxygen-derived free radicals are peroxy radicals (ROO⁻). The simplest form of these radicals is the hydroperoxyl radical (HOO⁻), which plays a role in the peroxidation of fatty acids. Free radicals can initiate lipid peroxidation chain reactions by removing a hydrogen atom from the methylene carbon of the side chain. The lipid radical then reacts with oxygen to form a superoxide radical. The peroxy radical initiates a chain reaction that converts polyunsaturated fatty acids into lipid hydroperoxides. Lipid hydroperoxides are very unstable and rapidly break down into by-products such as aldehydes (eg 4-hydroxy-2,3-nom) and malondialdehyde (MDA). Isoprostanes are another group of lipid peroxidation products resulting from the peroxidation of arachidonic acid, and their increased concentration has also been found in the plasma and exhaled air of asthmatic patients. Lipid peroxidation disrupts the integrity of cell membranes and leads to the remodelling of membrane structure. Hydrogen peroxide, superoxide radicals, oxidized glutathione (GSSG), MDA, isoprostane,

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

carbonyl, and nitrotyrosine can be readily determined in plasma, blood, or bronchoalveolar lavage samples as oxidative biomarkers using standard assays [6-8].

Fat-soluble vitamin E is concentrated in hydrophobic cells within the cell membrane and is the main defense against membrane damage caused by oxidants. Vitamin E donates an electron to the superoxide radical formed during lipid peroxidation. α -tocopherol is the most active form of vitamin E and the main antioxidant associated with the cell membrane. Vitamin E activates the cell division of cancer cells and inhibits the formation of free radicals [9-10].

GSH is present in all cellular compartments and is the main soluble antioxidant. The GSH/GSSG ratio is one of the main determinants of oxidative stress. GSH exhibits antioxidant activity in several ways. It neutralizes hydrogen peroxide and lipid peroxides through the action of GSH-Px. GSH donates its electron to H₂O₂ to be reduced to H₂O and O₂. GSSG is in turn reduced to GSH-by-GSH reductase, which uses NAD(P)H as an electron donor. GSH-Px is also important in protecting the cell membrane from lipid peroxidation. The reduced glutathione transports protons to membrane lipids and protects them from oxidative stress [11-12].

ROS can lead to DNA modifications in a variety of ways, including base degradation, DNA single- or double-strand breaks, purine-, pyrimidine-, or sugar-linked modifications, mutations, deletions or translocations, and cross-linking proteins. Most of these DNA changes are directly related to carcinogenesis, aging, neurodegenerative diseases, cardiovascular diseases and autoimmune diseases. Cigarette smoke, redox and non-redox metals such as iron, cadmium, chromium and arsenic are also involved in carcinogenesis and aging by forming free radicals or binding to thiol groups. The formation of 8-OH-G is the most well-known DNA damage due to oxidative stress and a potential biomarker of carcinogenesis [13-14].

Gene promoter regions contain homologous transcription factors. These transcription factor binding sites contain GC-rich sequences that are susceptible to oxidative attack. DNA synthesis of 8-OH-G at the transcription factor binding site can alter transcription factor binding and thereby alter the expression of associated genes, as shown for AP.1 and Sp-1 target sequences. In addition to 8-OH-G, 8,5'-cyclo-2'-deoxyadenosine (cyclo-dA) also inhibits cellular gene transcription when localized to the TATA domain. TATA-binding proteins initiate transcription by changing the bend of DNA. Binding to TATA-binding proteins can be disrupted by the presence of cyclo- α A [15-16].

Oxidative stress destabilizes microsatellite regions (short repeats). Redox-active metal ions and hydroxyl radicals increase microsatellite instability. Although single-stranded DNA breaks caused by oxidative damage are easily tolerated by cells, double-stranded DNA breaks caused by ionizing radiation can pose a serious threat to cell survival [17-18].

CpG group methylation in DNA is an important epigenetic mechanism that can lead to gene silencing. Oxidation of 5-MeCyt to 5-hydroxymethyluracil (5-OHMeUra) can occur via disaggregation/oxidation reactions of thymine or 5-hydroxymethylcysteine intermediates. It appears that in addition to regulating gene expression, DNA methylation also affects chromosome organization. Aberrant DNA methylation patterns induced by oxidative stress also affect DNA repair activity.

September 14-15, 2023, Naples, Italy

ROS can induce lipid peroxidation and disrupt the assembly of membrane lipid bilayers, which can inactivate membrane-bound receptors and enzymes and increase tissue permeability. Lipid peroxidation products such as MDA and unsaturated aldehydes can inactivate many cellular proteins by forming protein cross-links. Nominative 4-hydroxy-2 depletes intracellular GSH and induces superoxide production, activates the epidermal growth factor receptor, and stimulates fibronectin production. Lipid peroxidase agents such as isoprostane and thiobarbituric acid-reactive agents have been used as surrogate biomarkers of oxidative stress, with increased concentrations detected in exhaled air or lung or pulmonary lavage in patients with COPD [19-20].

ROS can cause peptide chain fragmentation, change in protein electrical charge, protein cross-linking, and oxidation of certain amino acids, leading to increased susceptibility to proteolysis by degradation by specific proteases. Cysteine and methionine residues in proteins are particularly vulnerable to oxidation. Oxidation of sulfhydryl groups or methionine residues in proteins causes conformational changes, protein cleavage and degradation. Enzymes that have metals at or near their active sites are particularly susceptible to metal-catalyzed oxidation. Oxidative modification of enzymes has been shown to inhibit their activity [21-22].

In some cases, selective oxidation of proteins may occur. For example, methionine can be oxidized to methionine sulfoxide and phenylalanine can be oxidized to o-tyrosine. Sulfhydryl groups can be oxidized to form disulfide bonds, and carbonyl groups can be inserted into protein side chains. Gamma rays, catalyzed metal oxidation, HOCl and ozone can lead to the formation of carbonyl groups.

ROS can induce the expression of many genes involved in signal transduction. A high GSH/GSSG ratio is important to protect cells from oxidative damage. Violation of this ratio activates redox-sensitive transcription factors such as NF- κ B, AP-1, activated T-cell nuclear factor, and hypoxia-inducible factor 1, which participate in the inflammatory response. Activation of transcription factors by ROS occurs through signal transduction cascades that transfer information from outside to inside the cell. Receptor tyrosine kinases, most growth factor receptors such as epidermal growth factor receptors, endothelial growth factor receptors and platelet-derived growth factor receptors, protein tyrosine phosphatases and serine/threonine kinases are targets of ROS. The extracellular signal-regulated kinases, JNK and p38, which are members of the mitogen-activated protein kinase family and are involved in many cellular processes, including proliferation, differentiation and apoptosis, can also be regulated by oxidants [23-24].

Under conditions of oxidative stress, cysteine residues in the DNA binding site of c-Jun, some AP-1 subunits, and inhibitory κ B kinase are reversibly S-glutathionylated. Glutathione and TRX have been reported to play important roles in regulating redox signaling pathways such as NF- κ B and AP-1, mitogen-activated protein kinase p38, and JNK.

In allergic rhinitis, several recent studies have examined the function of the NF- κ B pathway in a mouse model of allergic rhinitis. Studies have shown that in an OVA-induced allergic rhinitis model, markers of oxidative stress such as MDA levels and the Nrf2 and NF- κ B pathways are elevated. They correlate with signs of inflammation such as cytokine levels and histopathological findings in models of allergic rhinitis. After treatment with the antioxidant mangiferin, the markers decreased [25-26].

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Most of the research on oxidative signaling pathways in allergic rhinitis has focused on finding potential dietary antioxidants as alternative pharmacotherapy options to combat this disease. Thus, the current literature is somewhat limited in defining the complex and diverse molecular pathways of specific oxidative stress in allergic rhinitis. Recent research on dietary antioxidants for the treatment of allergic rhinitis is discussed in detail, including the natural dietary sources of each antioxidant [27-28].

Antioxidants capture and release free radicals from the body and control lipid levels (especially cholesterol) in the blood. It has anti-cancer effect, stops the growth of cancer cells, and can also inhibit cancer cells. Stimulates and simultaneously activates the regeneration of normal and healthy cells. Supports normal platelet function and reduces blood viscosity. Provides free blood circulation in the vessels and promotes the elasticity of the vessels. Antioxidants have anti-inflammatory and antibacterial properties. Antioxidants keep the skin fair and supple and prevent premature aging. It has the ability to restore and regulate the growth of collagen fibers, restore youthfulness to the skin, anti-allergic by neutralizing the release of histamine, improve memory, increase the body's resistance to stress, and lower blood sugar levels [29-31].

Objectives

The aim of the research was to study and analyze the key issue aspects, characteristics and effects of antioxidants in miscellaneous immunotherapeutic directions.

2. METHODS

The material of the article was the data from scientific publications, which were processed, analyzed, overviewed and reviewed by generalization and systematization. Research studies are based on a review/overview assessment of the development of critical visibility and overlook of the modern scientific literature. Use the following databases (for extensive literature searches to identify key points related to antioxidant properties in antiallergic drug therapy): PubMed, Web of Science, Clinical key, Tomson Reuters, Google Scholar, Cochrane Library, and Elsevier Foundations. National and international policies and guidelines were also reviewed and as well as grey literature.

3. RESULTS and DISCUSSION

Propolis and its components are important for health protection, prevention and treatment of minor diseases. Propolis is an integral part of (bio)cosmetics and a natural antibiotic in the treatment of ear, nose and throat infections. The use of propolis is very wide and includes the food industry, medicine (as an immunomodulatory agent that heals wounds and burns), cosmetics and hygiene products. Despite the good properties of propolis, many studies have shown that it causes allergic reactions in people who are allergic to propolis components. Several experimental studies have shown varying degrees of response to propolis and its ingredients. Sensitivity to propolis has been demonstrated in European studies. Allergic reactions that have occurred: contact dermatitis, stomatitis, pharyngeal eczema, swelling of the lips, pain in the mouth, peeling of the lips and shortness of breath. Several allergens have been isolated from propolis, namely 3-methyl-2-butenyl caffeine, phenylethyl caffeine, benzyl caffeine, geranyl caffeine, benzyl alcohol, benzyl cinnamic acid, methyl cinnamic acid, ferulic acid, and tectoric acid. In addition, propolis appears to be one of the most

TeMALab

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

common contact sensitizers and should be included in routine testing in children and adolescents prior to administration.

Propolis and its flavonoids are widely used in folk medicine as anti-inflammatory drugs and components of antifungal, antithrombotic, antiretroviral, antiallergic and anticancer drugs. Propolis has long been used in folk medicine. The anti-inflammatory effect of propolis is based on the inhibition of platelet aggregation, support for foot edema and arthritis in rats, the formation of eicosanoids, the production of cytokines and other important messengers to combat allergic diseases. Propolis is also known to have radiant properties. protects against damage to DNA by gamma and ultraviolet rays. For example, propolis protects the skin from many processes such as premature aging (wrinkles, flaking, dryness, capillary dilation and loss of collagen) and skin cancer. Particular attention should be paid to the therapeutic effect of propolis and its ability to induce the production of type I and III collagen and wound destruction. Propolis contains many compounds that speed up the healing process of the skin, such as tensile strength and elasticity, and promote the growth, expansion, and migration of human keratinocytes. These biochemical properties and changes in propolis may promote re-epithelialization and thus promise wound healing. It is worth noting that the use of propolis as a wound healing dressing has led to its economical, safe and painless use to protect against infections. Helps improve the rate of wound healing and reduce the number of dressing changes during micro healing. sewing materials and more. In a recent return to nature, modern man is looking for natural products with healing properties, mainly from plants and bees, which tend to fight allergies and/or inflammation. Laboratory and clinical studies of propolis, its related phytochemicals, as well as flavonoids and other antioxidants, indicate their use in the prevention and treatment of many diseases, including allergies. This review summarizes current knowledge about the mechanisms involved in the formation of the sensitizing and/or inflammatory potential of the polyphenolic/flavonoid components present in propolis, their importance in the treatment of allergic diseases, and their allergenic properties [32-34].

Propolis is widely used in folk medicine as an antioxidant and anti-inflammatory agent. Propolis has attracted the interest of scientists in elucidating its biological properties and discovering new treatments for many diseases such as diabetes, cancer, bacterial infections, allergic rhinitis and wounds. Propolis inhibited platelet aggregation, the formation of eicosanoids and supported arthritis, and also had a strong anti-inflammatory effect. Beneficial effect of propolis treatment in a child with eosinophilic ulcers. Recently, some studies have shown that propolis has important antibacterial properties in the saliva of periodontitis patients, while diphenyl-4-hydroxycinnamic acid, 3-prenyl-4-dihydrocinnamic acid and 22-dimethyl-6-carboxylic acid have been confirmed. be the main antibiotic with the highest activity against bacteria. Propolis can reduce dentin hypersensitivity (acute, sudden pain caused by tactile, osmotic, thermal, or other stimuli to exposed dentin) by reducing fluid conductivity in dentin. In addition, there is sufficient evidence that propolis and plant flavonoids, depending on their structure, can inhibit secretory processes, mitogen synthesis and intercellular processes, including their possible effect on the expression and activity of the original molecules. In addition, flavonoids can influence gene expression, pro-inflammatory cytokines, and cell receptors. The antioxidant and radical action of propolis and flavonoids helps fight allergic reactions and inflammatory processes. Several studies have shown that flavonoids can inhibit mast cell degranulation and reduce the release of

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

histamine, tryptase, IL-6 and IL-8 from cultured mast cells and macrophages. In addition, some flavonoids have the ability to release histamine, leukotrienes, prostaglandin D₂, IL-4, IL-13 and GM-CSF from human mast cells and basophils in a concentration-dependent manner. All evidence to date suggests that flavonoids may have powerful anti-inflammatory and anti-allergic effects, especially in mast cell-mediated allergic inflammatory diseases such as allergic rhinitis, asthma, Alzheimer's, skin and gastrointestinal diseases [35-37].

Propolis and its compounds are effective against allergic diseases because many antioxidants inhibit the release of histamine from mast cells and basophils. Mast cells can be induced as long-lived cells by immunological or chemical methods. Mast cells and basophils expressing high-affinity IgE receptors play an important role in allergic inflammation by releasing chemical mediators such as histamine, heparin, serine proteases, cytokines, chemokines, prostaglandins, leukotrienes, and PAF. After IgE-mediated degranulation, mast cells can granulate, which is an important process in the development and duration of allergy.

Unlike the hypoallergenic properties of propolis described above, propolis does not interfere with the immune process of mast cell degranulation. Potential beneficial effects of propolis-based products as an adjuvant in patients with asthma. In particular, an ethanol solution of propolis showed better results than an aqueous solution in preventing mast cell degranulation. A possible explanation is that the ethanol solution contains a much higher content of flavonoids. These benefits may be related to the presence of caffeic acid (CA) derivatives such as caffeic acid phenethyl ester (CAPE) and other active ingredients in the extract. Propolis inhibited histamine release by a compound described as concanavalin A, suggesting an unknown flavonoid and anti-inflammatory compound. Propolis has shown an inhibitory effect on the activity of myeloperoxidase, ornithine decarboxylase, protein tyrosine kinase, NADPH oxidase, and hyaluronidase in guinea pig mast cells. This anti-inflammatory effect can be explained by the presence of active flavonoids and cinnamic acid derivatives such as acacetin, quercetin, naringenin and CARE and CA. An alcoholic extract of propolis (3, 10, 30, and 100 µg/mL) had no significant effect on the A23187 ionophore and ovalbumin-induced histamine release. Several authors have suggested that only high concentrations of propolis can directly activate mast cells, promoting the release of inflammatory mediators through cytotoxic mechanisms that may be associated with the allergic process in propolis-sensitive individuals [38-40].

Quercetin is extremely safe in the treatment of allergic rhinitis. Quercetin has many other beneficial properties (antioxidant, anti-inflammatory, capillary-stabilizing, etc.). It is a strong inhibitor of degranulation of basophils and mast cells. In an immune response, basophils and mast cells sensitized by cell surface-bound IgE antibodies are largely degraded after repeated exposure to allergens. Degranulation requires the supply of energy and calcium (Ca²⁺) and leads to the simultaneous release of histamine, adenosine triphosphate and other mediators stored in the granules. During degranulation, mast cells use calcium-activated enzymes to assemble contractile microtubules that pull granules up to the cell membrane, where inflammatory contents leave the cell and trigger an allergic reaction. Quercetin prevents mast cell degranulation by preventing Ca²⁺ from entering the cell. Due to the activity of phospholipase A₂, additional inflammatory mediators, such as metabolites of arachidonic acid, are released outside the cell. Steroids are known to act as anti-inflammatory agents due to their ability to inhibit phospholipase A₂. Quercetin also inhibits several steps in the membrane eicosanoid pathway, including phospholipase A₂ and lipoxygenase. Several

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

authors have confirmed that quercetin can: (1) inhibit mast cell degranulation; (2) reduces airway hyperreactivity; (3) reduces mucus and collagen production; (4) reduces the recruitment of eosinophils and neutrophils; (5) reduce bronchial epithelial cell activation and expression of MMP-9 and MMP-12; (6) modulates the production of Th1/Th2 cytokines; (7) exhibits antifibrotic activity; (8) reduces collagen deposition by stimulating HO-1 activation; (9) reduces the production of IL-4, IL-5, CCL11 and LTB4 and increases IL-4 and increases the concentration of IFN- γ ; (10) reduces the synthesis of type I and type III collagen; and (11) regulates P-selectin expression by inhibiting NF signaling. These effects may be associated with attenuation of PI3 kinase, Akt and NF-kB signaling pathways. Quercetin, when combined with vitamin C, has been reported to reduce the symptoms of hay fever. Flavonoids have even been shown to inhibit enzymes that increase histamine release from mast cells and basophils: cAMP phosphodiesterase and calcium-dependent ATPase. Cyclic AMP phosphodiesterase cleaves cAMP; a large amount of cAMP blocks intracellular histamine stores. In addition, calcium-dependent ATPase breaks down ATP, releasing energy and promoting the release of Ca²⁺ from the cell membrane; High levels of intracellular Ca²⁺ also cause the release of histamine from storage granules. Quercetin has a high affinity for mast cells and basophils; stabilizes membranes, prevents the release of histamine, and may inhibit two enzymes that control the release of leukotrienes involved in the asthmatic response. By blocking the release of histamine and leukotrienes into the bloodstream, quercetin prevents allergy symptoms such as nasal swelling, nasal congestion, sneezing, watery eyes, and itchy eyes and nose [41-45].

The mechanism of the allergenic action of flavonoids, such as luteolin, quercetin and baicalein, which participate both in the IgE-mediated immune response and in the sensitization and action phase, is based on their structure and ability to inhibit: (1) hexosaminidase enzyme; as a key factor in reducing mast cell degranulation), phospholipase A2 (PLA2) and 5-lipoxygenase (5LO). (2) transport of ATPase for histamine secretion by rat mast cells. (3) human basophils stimulated by allergens; (4) Synthesis and secretion of cytokines IL-4, IL-13 and CD40 ligand (important for the differentiation of B-lymphocytes into IgE-producing cells), granulocyte-macrophage colony-stimulating factor, GM-CSF, interleukin (IL)-6 and tumors with necrosis factor (TNF)- α . At present, many of the mechanisms by which flavonoids inhibit histamine synthesis and release in response to high-affinity IgE receptor (Fc ϵ RI) cross-linking are unclear and require further investigation. According to many researchers, due to their antioxidant and anti-allergenic properties, flavonoids can inhibit the formation and release of many allergic mediators, including Th2-type cytokines (IL-4 and IL-13), as well as CD40 expression. an important ligand in many intercellular interactions. These cells (such as mast cells and basophils) express the immunoglobulin E (IgE) receptor with high affinity, leading to an increased inflammatory response. It turns out that to produce IgE, B cells need to receive two signals. the first signal comes from the cytokines IL-4 and IL-13, and the second comes when CD40L, which is induced on the surface of T cells after allergen exposure, binds to CD40 on the cell surface. is important for activation and induction of allele exchange in B cells. Reactive T cells, when encountering an allergen, express CD40L and can therefore target B cells, monocytes, DCs and epithelial cells using CD40. Polyphenol-flavonoid compounds control the Th1/Th2 balance and inhibit the formation of antigen-specific IgE antibodies by influencing the formation of allergic-IgE complexes and binding this complex to its receptor (Fc ϵ RI) on mast

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

cells and basophils. In addition to Th2 cells, tannins isolated from apples can prevent food allergy by increasing the number of $\gamma\delta$ TCR T cells in intestinal epithelial lymphocytes.

It has been shown that the inhibitory effect of some flavonoids on mast cell degranulation results from the modulation of Ca^{2+} receptor channels in the cell membrane and β -exosaminidase as a marker of mast cell degranulation. For example, apigenin, luteolin, 3,6-dihydroxyflavones, fisetin, kaempferol, quercetin and myricetin have been found to inhibit hexosaminidase release from mast cells with IC50s less than 10 μ M, while quercetin, quercetin, scutellarin inhibit PLA2 with IC50s in the range 12.2 to 17.6 μ M. In addition, luteolin, apigenin and fisetin are the most potent inhibitors of IL-4 and IL-13 synthesis, while 3-hydroxyflavone, kaempferol, quercetin, eriodictyol, futin and 7-hydroxyflavone also inhibit IL-4 production, but to a lesser degree. Classification. Classification. Sirsilol (3',4',5-trihydroxy-6,7-dimethoxyflavone) produced 97% inhibition of 5LO activity in rat basophils and 99% inhibition of cysteinyl leukotriene release from rat and guinea pig lungs. In particular, quercetin and kaempferol can inhibit IL-4 synthesis with an IC value of 15.7–18.8 μ M. Inhibitory effects of kaempferol on the biological activity of IL-5 and histamine release from basophils and mast cells. Hydroxylation of IL-4, 7 and 4' and the presence of OH at position 3 or 5 are required for maximal inhibition, whereas glycosylation at position 3 reduces activity [46-48].

By inhibiting IL-4 mediated signaling, flavonoids prevent differentiation of primary CD4+ T cells into effector T cells by inhibiting aryl hydrocarbon receptor (AhR) and NF- κ B activation. AhR is a ligand-activated transcription factor that mediates the toxic and biological effects of many aromatic environmental pollutants such as dioxin.

The antioxidant activity of flavonoids is mediated by nuclear factors/AhR in association with erythroid factor 2 (Nrf2) and results in increased activity of antioxidant enzymes such as peroxidase, glutathione peroxidase, catalase, peroxiredoxin, and heme oxygenase-1. By reducing oxidative stress, propolis and its flavonoids can inhibit the oligomeric nucleotide-binding domain, the leucine-rich repeat gene family, and the pyrine domain-containing inflammasome 3 (NLRP3) [49-50].

The anti-inflammatory effects of flavonols (quercetin, rutin and morin) and flavanones (hesperetin and hesperidin) have been studied in animal models of acute and chronic inflammation. The anti-inflammatory potential of propolis and its flavonoids is attributed to several mechanisms, such as: (1) strong antioxidant activity and free radical scavenging, (2) regulation of inflammatory cell activity, (3) inhibition of arachidonic acid, a metabolic enzyme (phospholipase). A2, COX, LOX) and nitric oxide synthase, (4) regulating the production of pro-inflammatory cytokines and mediators and (5) downregulating the expression of pro-inflammatory genes. It should be noted that the main flavonoid processes that determine anti-inflammatory activity consist of: (1) inhibition of pro-inflammatory enzymes (COX, LOX, and inducible NO synthase); 2) inhibition of NF- κ B transcription factors and activation of protein -1. (AP-1); (3) activation of phase II detoxification enzymes by antioxidant factors including glutathione reductase, glutathione peroxidase, heme oxygenase, γ -glutamylcysteine synthetase, superoxide dismutase, and catalase; and (4) modulating signalling pathways such as protein kinase C, mitogen-activated protein kinase (MAPK), and erythrocyte nuclear factor-associated factor 2 (Nrf2), whose protein products are involved in detoxification and "elimination of reactive and electrophilic oxidants through functional conjugation reactions." and increase the oxidative capacity of cells, its action leads

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

to inhibition of MCP-1 expression and adhesion of monocytes to endothelial cells, as well as migration and activation of p38 MAPK [51-53].

The document confirmed the anti-inflammatory effects of propolis and flavonoids such as quercetin, luteolin, anthocyanins, hyperin and alpinetin on the TLR4/NF- κ B/NLRP3 signalling pathway. It is based on interfering with several steps of NLRP3 inflammatory signaling in vitro and in vivo, reducing and/or inhibiting the expression of pro-inflammatory NLRP3 factors such as IL-1 β , IL-18, NLRP3 and caspase-1 β . Oligomerization with signalling molecules (eg, TLR4/NF- κ B/NLRP3, PPAR γ , TXNIP, and Syk/Pyk2). For example, EGCG reduces peritonitis by inhibiting NLRP3 expression and IL-1 β release in mice treated with NMSUL sodium urate crystals in NMSUL3 crystals) binds to a thioredoxin-interacting protein (TXNIP) in THP-1 cells, while quercetin inhibits NLRP3 expression and IL-1 β and caspase-1 activity in human colon epithelial cells [54-55].

The anti-inflammatory mechanism of resveratrol is based on its ability to remove ROS, inhibit COX, and activate several pro-inflammatory signaling pathways, including sirtuin-1 (Sirt1), which inhibits TLR4/NF signaling. κ B/STAT, which leads to a decrease in the production of cytotoxic and pro-inflammatory factors by passive immunity cells, macrophages and mast cells. Therefore, the addition of resveratrol to the human diet may be promising for the treatment of immune diseases, but only in the form of nanoparticles due to its rapid metabolism in the body.

Despite the low gut bioavailability of flavonoids and hence low effective plasma and target tissue concentrations, even low flavonoid concentrations appear to be sufficient to activate Keap1/Nrf2/ARE and Keap1/Nrf2/ARE NF- κ B signaling as main factor. . health improvement system. The main mechanisms of anti-inflammatory action of flavonoids in the intestine are: (1) strong antioxidant properties and/or radical scavenging, (2) the effect of nitric oxide (NO) on metabolism, (3) inhibition of anti-inflammatory processes. effect, (4) inhibition of lipoxygenase and reduced production of leukotriene B4 (LTB4), (5) preservation of colonic absorption, and (6) influence of TLR and inflammation. Therefore, it is possible that propolis and its flavonoids are suitable compounds for limiting or even preventing the development of allergic/inflammatory reactions.

Propolis and flavonoids have been shown to inhibit IL-10, IL-4 and IL-13. IL-4 and IL-10 inhibit IL-12 induced IFN- γ secretion. In addition, IL-10 counteracts many of the pro-inflammatory effects of TNF- α and IL-1 β , while IFN- γ can inhibit monocyte production of IL-4 and IL-10 [56-58].

There is growing evidence of an important role for arginase in patients with asthma. Arginase 1 expression and arginase and/or arginase activity are elevated in the airways and serum of asthmatic patients, and there is a correlation between arginase expression in bronchial brushes, serum arginase activity, plasma concentrations of L-arginine and its metabolites, and disease severity. lung function) and Fe (NO). In addition, ARG1 and ARG2 polymorphisms are associated with asthma, asthma severity (pulmonary function, AHR), and decreased response to β 2-agonists and glucocorticoids. In addition, recently there has been an increase in the expression of arginase 1 and 2 in the nasal mucosa and the activity of arginase in the blood serum.

Considered alternative medicine, herbal medicine is one of the complementary methods using natural extracts as medicines or treatments. In recent years, much attention has been paid to

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

natural products in disease prevention due to their many health benefits and remarkable lack of toxicity and side effects. Many plant foods, such as grains, nuts, cereals, soybeans, spices, flaxseeds, fruits, vegetables, medicinal plants, and herbs, contain various phytochemicals such as phenols, carotenoids, alkaloids, nitrogen and organosulfur compounds, and vitamins [59-61].

Recent *in vivo* and *in vitro* studies have demonstrated the potential anti-inflammatory role of some known natural antioxidants. Combinations of natural antioxidants provide various mechanisms to reduce tissue oxygen metabolites, modulate signaling pathways, and regulate transcription factors, and may play a key role in reducing species-dependent reactive oxygen species (ROS) damage. Many bioactive plant compounds, including several polyphenols, have recently been tested for vascular disease.

Asthma and chronic obstructive pulmonary disease (COPD) are chronic inflammatory airway diseases characterized by bronchial hyperreactivity and airflow limitation with acute bronchospasm, airway inflammation, chronic mucositis, and airway wall remodeling. Significant evidence suggests that oxidative stress, one of the causes of asthma, acts as a central event in the inflammatory response by activating transcription factors such as nuclear factor- κ B (NF- κ B) and protein-1 (AP-1), mediators of pro-inflammatory gene expression. Thus, bioavailable antioxidants can protect against the direct harmful effects of oxidants and fundamentally alter inflammation in the pathogenesis of various respiratory diseases [62-64].

The lungs have several natural antioxidant mechanisms to counteract the overproduction of oxidants (ROS, reactive nitrogen species, and lipid peroxides), including enzymatic and non-enzymatic antioxidants. These antioxidant defense systems form a tightly regulated network that resists any changes in the redox environment of the intracellular and extracellular spaces. Enzymatic antioxidants include catalase, glutathione peroxidase (GPX), and superoxide dismutase (SOD), while non-enzymatic antioxidants include vitamin C, vitamin E, albumin, uric acid, ceruloplasmin, and glutathione (GSH). Changes in these enzymatic and non-enzymatic antioxidants can alter ROS homeostasis in bronchial cells [65-67].

Deficits in intrinsic antioxidant defense have been reported in asthma. Devereux and colleagues hypothesized that people in Western societies gradually reduce their intake of fruits and vegetables, thereby reducing the antioxidant defenses of the lungs, making them more sensitive to inhaled irritants and allergens. Since many antioxidants are obtained from food, particular attention is being paid to the availability of antioxidants (vitamins A, C and E, polyphenols and carotenoids) and how they can help protect people suffering from dementia, oxidative stress and/or airway inflammation.

Plants have two main mechanisms for detoxifying harmful oxidants. One of them is the direct enzymatic cleavage of oxidative radicals using SOD, catalase, ascorbate peroxidase, peroxidase, glutathione reductase, and monodehydroascorbate reductase. These enzyme systems convert various oxidative radicals into reduced products. The second method is to create antioxidant molecules such as vitamin C and vitamin E. These antioxidant compounds have a hydroxyl group (-OH) in an electron-deficient ring structure that is highly sensitive to ROS [68-70].

The active ingredient in turmeric is curcumin, a polyphenolic plant substance with anti-inflammatory, anti-amyloid, antiseptic, anti-cancer, anti-allergic, and antioxidant properties. In addition to its use in cooking, curcumin has been used as a folk remedy for liver disorders

September 14-15, 2023, Naples, Italy

(especially jaundice), indigestion, urinary tract disorders, blood cleansers, arthritis (rheumatism), insect bites, skin disorders, and atherosclerosis. Curcumin has been shown to be eight times more effective than vitamin E in preventing lipid peroxidation. Curcumin is also believed to play a role in reducing oxidative stress by inhibiting the formation of nitric oxide (NO), scavenging or neutralizing free radicals, especially superoxide anions, and inhibiting free radical-induced oxidative chain reactions [71-73].

α -lipoic acid (LA), an organosulfur compound derived from octanoic acid, is a naturally occurring compound also known as thioacid. LA is readily absorbed from food and rapidly converted to the reduced form of dithiol, dihydrolipoic acid (DHLA). LA and DHLA are powerful antioxidants. Most of the LA in food is processed by lipoamide-containing enzymes and is associated with the amino acid lysine (lipopolysin). Plant sources rich in lipolysin include spinach, broccoli, and tomatoes. LA is a non-vitamin nutrient essential for life. It is not classified as a vitamin because it is produced in the body. It is often involved in the oxidative decarboxylation of keto acids and has been shown to be a growth factor in some organisms. While LA is involved in cellular energy production, its primary role as a dietary supplement may be as a powerful antioxidant. Unlike other antioxidants, LA is soluble in fats and water, easily absorbed and transported through cell membranes. LA directly quenches reactive oxygen species, regenerates/recycles endogenous and exogenous antioxidants such as vitamins C and E and GSH, removes redox metals including Cu(II) and Fe(II), restores oxidized proteins and regulates the activity of transcription factors, those like NF. -kV and LA have the ability to regenerate other antioxidants such as vitamin C, vitamin E and GSH for later use after free radical scavenging [74-77].

An antioxidant is a molecule that prevents the oxidation of other molecules. Oxidation releases free radicals, which scientists believe cause many diseases. When the body receives enough antioxidants, it can fight free radicals on its own. In fact, the antioxidants, minerals, fiber, and other substances found in fruits, vegetables, and grains protect the body from disease, but taking large doses of additional antioxidants does not have much effect. Among the substances that act as antioxidants against harmful free radicals, the most common are vitamin A, vitamin C, vitamin E, selenium, flavonoids, lignan, and lutein. Sources of vitamin E are nuts, cereals, vegetables and vegetable oil. Sources of vitamin C include citrus fruits, tomatoes, green leafy vegetables, and strawberries. Sources of vitamin A include apricots, melons, broccoli, sweet potatoes, carrots, cabbage, and plums. Sources of selenium: nuts, fish, red meat, cereals, eggs, garlic and milk. Sources of flavonoids: soy, red wine, pomegranate, blackberry, currant and tea. Sources of lignans are flaxseed, barley, rye, whole grains, and oats. Sources of lutein: kiwi, spinach, Brussels sprouts, green tea and broccoli.

Antioxidants are substances that protect the human body from harmful particles and especially from free radicals. Free radicals are unstable, highly aggressive and active molecules that damage healthy cells and cause: frequent colds and flu, exacerbation of chronic diseases, premature aging of the body, the risk of atherosclerosis, heart attack, accidents, cerebrovascular diseases, cataracts and cancer. Antioxidants can be called the ecological side of the human body. These are "C", "E", vitamin A, lupine, lycopene, some amino acid complexes, the trace element selenium and some plant extracts. Plant foods are the main source of antioxidants. These are fruits, vegetables, herbs, green tea and much more. These products also contain a large number of vitamins, minerals and other biologically active substances necessary to keep the body in good shape.

It is believed that vitamin A and the retinoic acid produced from it protect the body from surrounding carcinogens. Carotene is formed from vitamin A. American scientists have proven that foods rich in carotene protect against cancer. Colourful fruits and vegetables contain a lot of carotenes. With a sufficient amount of vitamin-A in the body, the skin becomes healthy and smooth, and the vessels remain elastic since this vitamin prevents the formation of loops in the vessels [78-80].

The activated mineral zeolite (clinoptilolite) 500 mg "Geomin Forte" developed and characterized by an antioxidant effect. Unlike traditional antioxidants, it stimulates the body's antioxidant system and is a direct antioxidant. The activated natural mineral zeolite (clinoptilolite) acts directly on the cell membrane as a surfactant, which is an electron donor. Geomin Forte is 200 times more antioxidant than vitamins C and E. Geomin Forte can be used for poisoning (used as the best food absorbent), infections, occupational poisoning, chronic metal poisoning and chronic exposure and also against the functional state of the immune system over time and in any case, with allergic diseases.

One of the most powerful antioxidants is vitamin C (ascorbic acid). Vitamin E, which is assigned the role of a fat solvent, traps free radicals in the membrane, which consists of lipid molecules, and ascorbic acid performs this work in the water space between cells. Vitamin C also works in the circulatory system, protecting hemoglobin from oxidation, providing iron stores in the body, and regulating cholesterol levels. The human body can absorb 2-3 g per day, the excess is excreted by the kidneys. However, taking vitamin C in large quantities is not recommended, practice shows that this will not lead to anything good. High concentrations of vitamin C are found in asparagus, peas, beets, black currants, cabbage, cherries and strawberries.

Selenium provides antioxidant protection and slows down aging. Selenium improves mobility and regulates thyroid function. Selenium-rich beef and pork liver and kidneys, fish and plant products - wheat bran, wheat seeds, legumes, sunflowers, nuts, corn, tomatoes, mushrooms, garlic and whole grain bread. Lycopene is one of the most powerful carotenoids and has been shown to protect against breast, lung, endometrial and prostate cancer. Contains mainly tomatoes and tomato puree (1 tablespoon covers full daily dose).

Taking into account the above properties of the zeolite mineral (clinoptilolite), the activated clinoptilolite 500 mg "Geomin Forte" developed by us is characterized by an antioxidant effect. Unlike traditional antioxidants, it stimulates the body's antioxidant system and is a direct antioxidant. The activated natural mineral zeolite (clinoptilolite) acts directly on the cell membrane as a surfactant, which is an electron donor. Geomin Forte is an antioxidant, 200 times stronger than vitamins C and E. This allows it to be used for poisoning (it is used as the best absorbent for food poisoning, infectious, occupational, chronic metal poisoning and chronic exposure). And also, against the background of the functional state of the immune system for a long time and to help with allergic diseases.

Alpha Lipoic Acid is a general antioxidant that protects against oxidation and helps remove toxins from the body. Alpha lipoic acid may increase physical endurance. Alpha lipoic acid is also found in spinach, rice, and kale, as well as animal products containing animal acids: heart, liver, kidney, milk, eggs, and beef.

Green tea and cranberry extract contain a large number of polyphenols and flavonoids, very powerful natural antioxidants with a wide spectrum of action.

Lutein protects the retina by absorbing harmful UV rays. Lutein may reduce the risk of retinal degeneration, which is a cause of age-related blindness. Several large studies have shown that people who consume a lot of lutein have a lower risk of developing cataracts.

Lutein is found in dark green leafy vegetables such as spinach, kale and broccoli, various fruits and breads. Carrots, zucchini and other vegetables containing orange and yellow pigments, as well as egg yolks, are also sources of lutein. All of these foods are an important part of a healthy diet. However, it is difficult to get enough lutein daily from a regular diet, as most foods are very low in lutein. Therefore, an important source of lutein are specially prepared natural preparations - biologically active food supplements, standardized according to the content of this active food supplement.

Antioxidants are essential for the survival of all organisms. The human body produces its own antioxidants. For example, glutathione is a cellular antioxidant. Plants and animals, like all other life forms, have their own defense mechanisms against free radicals and oxidative damage. Thus, antioxidants are found in all whole foods of plant and animal origin, and an adequate intake of antioxidants is important. In fact, human life depends on the intake of certain antioxidants, namely vitamins C and E.

Oxidation is a natural process. However, it can cause chain reactions that damage human cells. Vitamins, minerals, and enzymes called antioxidants can prevent these reactions. Antioxidants are considered an important part of a healthy diet that supports body systems, including connective tissue, respiratory, digestive, and cardiovascular systems. The best way to avoid deficiency is to get your daily dose of antioxidants from healthy plant foods like fruits and vegetables. However, you may need supplements to compensate for occasional oxidative stress (especially in elite athletes) or nutritional deficiencies.

Simply put, free radicals are highly reactive molecules that have a place for electrons and try to fill it by taking electrons from other molecules. Filling the free space makes it safe, but it has already done its "dirty" work. Having lost an electron, the molecule turns into a free radical and continues to fill the need for the missing electron. Free radical molecules are constantly formed in the human body due to a variety of redox processes that ensure the proper functioning of all organs and systems.

Under natural conditions, the number of free radicals is small and their pathological effect on the cells of the body is suppressed by antioxidants (when eating foods containing these substances). However, in case of metabolic disorders, under the influence of toxins, the protection of antioxidants weakens, the balance of the cell is disturbed, and the number of free radicals increases significantly.

High levels of free radicals are the starting point for many diseases, from the common cough to cancer. Violations appear in the body, inflammatory processes develop, atherosclerosis develops, the digestive system is disturbed, malignant tumors, heart disease, etc. appear. The human immune system plays an important role in the fight against free radicals. The appearance of signs of aging is associated with a decrease in immunity and the action of free radicals: weakness in the muscles and skeleton, loss of skin elasticity, decreased functioning of the senses - hearing and vision, as well as problems and various mental processes.

ABSTRACT

The aim of the research was to study and analyze the features of factors effect on dental hygiene, oral health and dental education of common people. The importance of evidence-based treatment and developed ways to implement data science systematically through funding, education, and fellowships. The translation of new knowledge discovered by big data analytics into evidence-based dental practice has potential to improve public oral health outcomes. Precision public health has been defined as a method to improve the ability to prevent disease, promote health, and reduce health disparities in populations by applying emerging methods and technologies for measuring disease, pathogens, exposures, behaviors, and susceptibility in populations; and developing policies and targeted implementation programs to improve health. Appropriate oral hygiene behavior, including frequent daily tooth brushing, using dental floss, and receiving regular dental checkups, can help prevent dental caries and periodontal disease. Oral hygiene behavior is related to a variety of factors, including oral hygiene knowledge. Furthermore, it has been reported that students who had acquired dental knowledge during the university life improved their oral health status. In health care globally, there has been a focus on person-centered care, which is an individualized, holistic approach to care where the

decision making is shared by the clinician and the client, and at times, includes the client's family or caregiver. Instead of viewing the client as a collection of symptoms, person-centered care fosters communication to take into consideration the client's values and goals. Dental hygienists have an ethical responsibility to provide opportunities for patients to make informed decisions about their treatment. Diagnosis refers to the identification of a disease based on the presentation of signs and symptoms. Health care professionals in all fields use diagnosis as a means to identify and discuss diseases with patients and formulate a plan for treatment.

Keywords: Features, Factors, Effect, Dental Hygiene, Oral Health, Dental Education.

1. INTRODUCTION

Dental hygiene education has been increasing in recent years. Evidence suggests that baccalaureate dental hygiene graduates have greater depth and breadth of knowledge, improved cognitive abilities related to research use and critical thinking, increased confidence to take action in their practice resulting in greater contributions in interprofessional contexts, and more career opportunities outside of private clinical practice. Studies have also demonstrated that baccalaureate dental hygiene graduates are more likely to practice in alternative settings, such as public health authorities and other community agencies, hospitals, educational institutions, professional associations and regulatory bodies, research laboratories, industry, and independent practice [1-3].

Appropriate oral hygiene behavior, including frequent daily tooth brushing, using dental floss, and receiving regular dental checkups, can help prevent dental caries and periodontal disease. Oral hygiene behavior is related to a variety of factors, including oral hygiene knowledge. In Japan, previous studies reported that university students with better oral hygiene knowledge practiced better oral hygiene behavior. In other countries, similar results have been reported. Furthermore, it has been reported that students who had acquired dental knowledge during the university life improved their oral health status [4-5].

Children's quality of life, academic performance, and future achievement can all be negatively affected by poor dental health. The present study aimed to assess the need for dental health services and the factors influencing their utilization using the Andersen health care utilization model among school children. Dental caries is the most critical indicator of oral health, while dental appointments are a marker of dental care. The school setting is thought to be the most efficient approach to reaching out to children's families and communities.

Despite the preventive nature of oral diseases and their significance for general wellbeing, poor oral health is highly prevalent and has unfavorable ramifications for children around the world. Indigenous children in Australia experience disproportionate rates of early childhood caries compared to their non-Indigenous counterparts. Therefore, the paper collates parental experiences and generate an understanding of facilitators for Indigenous childhood oral health. Child-level facilitators include oral hygiene routines and regular water consumption. Family-level facilitators include familial ties, importance of knowledge, and positive oral health beliefs. Community-level facilitators include generational teaching, helpful community resources, and holistic health care. Recommendations from findings include the following: exploration of Indigenous health workers and elder participation in oral health initiatives; inclusion of Indigenous community representatives in mainstream oral health discussions; and incorporation of child-level, family-level, and community-level facilitators to increase support for efficacious oral health programs [6-9].

Compromised nutritional intake due to eating disorder related behaviors, such as binge eating and purging, can lead to multi-system medical complications, including an irreversible impact on oral health. However, dental anxiety, fear or embarrassment may hinder individuals with an eating disorder from seeking assistance for their oral health concerns. As key health professionals in eating disorder treatment, dietitians are well positioned to provide basic dental screening, however, their capacity to perform this role in practice has not been established. The aim of this review was to identify current evidence on the role of dietitians in promoting oral health among individuals with eating disorders [10-12].

Eating disorder related behaviors including binge eating and purging are known to lead to significant medical and dental complications. Barriers including dental anxiety or embarrassment may hinder individuals with an eating disorder from seeking assistance for their oral health concerns. Dietitians form part of the primary care team for eating disorders and therefore are well positioned to provide basic dental screening and education, however, their capacity to perform this role in practice has not been established. A review of the literature was conducted and focused on guidelines for oral health promotion, dietitian knowledge, attitudes and practices towards oral health promotion, and the availability of resources in this area. Recommendations that supported the role of the dietitian in oral health promotion were identified. Additionally, dietitians were found to be aware of the importance of oral health, however were not providing referrals. Overall, there was limited evidence of adequate oral health resources to assist dietitians. Despite the limited evidence, it highlights their capability to provide pre-emptive oral health promotion in other clinical settings. Further research is needed to explore how to support dietitians to promote oral health among populations with an ED [13-15].

Vitamin D is synthesized in the skin after exposure to natural sunlight or absorbed through the dietary and supplemental intake. The vitamin D status depends on several factors such as pigmentation of the skin, amount of sun exposure, the latitude of living, season, vitamin D intake, age, sex, overweight/obesity, malabsorption, and medication such as corticosteroids. Receptors for vitamin D are expressed in many types of tissues and cells, indicating a potential influence on several biological processes, such as modification of the adaptive and innate immune system, with anti-microbial and anti-inflammatory effects, and suppression of autoimmune responses. Inadequate vitamin D levels have been associated with several extra-skeletal, and autoimmune diseases and chronic pain conditions. Vitamin D plays a crucial role in preserving phosphate and calcium homeostasis and enables normal mineralization, growth, and bone remodeling. Long-lasting vitamin D deficiency may lead to rickets, muscle weakness, bone pain, and growth impairment in children. Vitamin D deficiency has also been linked to enamel defects and increased risk of dental caries. The development and mineralization of both the baby's primary teeth during pregnancy and permanent teeth after birth are vulnerable to disturbances in vitamin D and mineral metabolism. This is supported by a recent mother-baby pair study where maternal vitamin D levels (< 50 nmol/L) during the third trimester of pregnancy, were associated with higher caries experience in the primary dentition of children at 6 years of age compared to children of mothers with sufficient third-trimester vitamin D levels. Vitamin D may also influence oral health conditions through its anti-inflammatory and anti-microbial effects. Studies of serum vitamin D status in children and adolescents with Juvenile Idiopathic Arthritis (JIA) are often characterized by small sample sizes and a lack of healthy controls and show inconsistent results regarding serum vitamin D levels, the prevalence

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

of insufficiency and deficiency, and the association between serum vitamin D status and disease activity. However, inadequate vitamin D levels appear to be common among young individuals with JIA. Serum vitamin D levels, JIA activity, and oral health conditions might be affected by ethnicity, lifestyle, dietary habits, socio-economic and environmental factors, and also genetics [16-17].

Objectives

The aim of the research was to study and analyze the features of factors effect on dental hygiene, oral health and dental education of common people.

2. METHODS

The material of the article was the data from scientific publications, which were processed, analyzed, overviewed and reviewed by generalization and systematization. research studies are based on a review/overview assessment of the development of critical visibility and overlook of the modern scientific literature. use the following databases: (for extensive literature searches to identify the manifestation of features of factors effect on dental hygiene, oral health and dental education of common people). PubMed, web of science, clinical key, Tomson Reuters, google scholar, Cochrane library, and Elsevier foundations. national and international policies and guidelines were also reviewed and as well as grey literature.

3. RESULTS and DISCUSSION

Digital dentistry and superior visualization for diagnosis are used in dental practices and are becoming more efficient as a result of technological advances. In dentistry, dental informatics relates to information management, communication, and the deployment of new technologies in clinical practice and research. Management of information in a dental office includes storing and using information generated while working directly with patients, arranging visits, and running dental practices. The dental office uses this system as an information management system. The existence of information systems is a prerequisite for all human creativity today.

The best care for an individual, precision medicine takes various factors into account in addition to disease history, such as an individual's environment, genome, and socioeconomic status. By combining these elements, a profile can be generated for each individual that better predicts their health outcomes and addresses risk factors. Combined information provides an opportunity to tailor treatment to the needs of the individual patient based on their risk factors. To successfully integrate precision medicine into oral healthcare, three major challenges must be addressed: development of up-to-date evidence-based guidelines, integration of large analytical data sets, and translation of new knowledge into routine clinical care delivery. In the fields of dentistry and oral health, implementation of these factors represents a major obstacle to the delivery of precision oral medicine [18-20].

The World Dental Federation's (FDI's) theoretical framework of oral health builds on the World Health Organizations' Commission on Social Determinants of Health report and includes individual, environmental, and social determinants of oral health through a life course. A central part of the FDI's framework, the core elements of oral health, refers to progression, impact, and severity of diseases and conditions as well as the abilities, functions, and capacities related to oral health. In addition, the framework includes these components: overall health and well-being, moderating factors, and driving determinants. Altogether, the framework describes oral

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

health status, the connection to overall health and well-being, and elements that can determine or affect how an individual scores their oral health, as well as factors that can affect it [21-22].

The importance of evidence-based treatment and developed ways to implement data science systematically through funding, education, and fellowships. The translation of new knowledge discovered by big data analytics into evidence-based dental practice has potential to improve public oral health outcomes. Precision public health has been defined as a method to improve the ability to prevent disease, promote health, and reduce health disparities in populations by applying emerging methods and technologies for measuring disease, pathogens, exposures, behaviors, and susceptibility in populations; and developing policies and targeted implementation programs to improve health [23-25].

Previous studies suggest that a family member should be psychologically prepared to respond to health dangers or circumstances. The number of dental clinic visits in a year is used as a standard measure to analyze dental health service (DHS) utilization. Family income, parents' education, employment, health insurance, parental preventative practice, behaviors, and access to dental care are the factors that influence the utilization of DHS. Three factors that affect oral health care visits are dental anxiety, a preference for dental health protection, and a family dental health problem. According to Andersen's model, the child's age, the number of family members, education, the time required to access a dental service, and a positive parental attitude toward a child's oral health influence dental health service utilization. Most of the children needed dental health services, but they were underutilized. The majority of study participants underwent restoration treatment. Most schoolchildren had oral diseases such as dental caries, periodontal disease, and malocclusion. Programs that promote oral health and the availability of public hospitals are necessary to boost the use of dental services, improve parental and children's attitudes toward them, make them more accessible and affordable, and remove any remaining hurdles [26-28].

Over the past 50 years, there has been a marked improvement in clinical measures of oral health, partly due to the wide use of fluoridated toothpaste and a stronger focus on disease prevention in the dental health services of most Western countries. However, many studies have found rather weak associations between clinical and self-reported measures of oral health. Thus, when evaluating the oral health of a population, it is important to use both clinical and self-perceived measures. Dental caries is a costly and very common disease, especially in pregnant women. Reasons such as not paying attention to oral health, poor diet and also lack of adequate education in this regard cause this to happen. Performing well-designed educational interventions using primary health system's forces, can improve oral health of pregnant women and help control this disease [29-31].

Dental caries is the most prevalent global infectious diseases with considerable economic and quality-of-life burdens. There is enough evidence to conclude that poor oral health behaviors and bad dietary habits such as excessive consumption of sweets are important risk factors associated with dental caries. One of the groups most prone to tooth decay are pregnant women. According to reports, tooth decay in these people was up to 2.9 times more than normal people. They were also more likely to develop gingivitis and generally, their oral health was more at risk. Also, periodontitis is a common condition in pregnancy, and these two conditions are related to each other due to various factors. Periodontitis during this period can lead to negative pregnancy outcomes such as preterm birth and low birth weight. Maternal oral health status also can affect developing early childhood caries that may result in so many consequences for

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

child's health in the future. The importance of oral health before, during and after pregnancy has attracted the attention of policymakers, scientific foundations, agencies, and Primary Health Care Providers (PHCPs) who serve pregnant women and young children. It is recommended that pregnant women receive oral health education and self-care behavior education to prevent dental infections during pregnancy period. A recent systematic review of oral health knowledge and awareness in pregnant women concluded that they had poor level of knowledge and awareness [32-33].

Many studies have reported risk factors for tooth loss. Oral health instruction is considered effective at improving oral health behavior and oral health. However, few studies have examined the relationship of dental clinic factors, such as the number of dental hygienists and implementation of oral health instructions, with tooth loss. Here, we conducted a multilevel analysis to clarify the dental clinic risk factors associated with tooth loss. Many studies have reported the risks of tooth loss. Since individual- and tooth-level factors are involved in tooth loss, some studies have conducted multilevel analyses to identify the risk of tooth loss. Tooth loss is associated with the type of dental visit and the risk of tooth loss was lower in those who had regular dental checkups compared with those who received treatment only. The number of people visiting dental clinics for dental checkups is increasing. Therefore, it is important to clarify the dental-clinic factors related to dental visits. For example, oral health instructions improve oral health behavior and oral health. However, few studies have examined the relationships of dental-clinic factors, such as the number of dental hygienists and the provision of oral health instructions, with tooth loss [34-35].

A growing body of evidence suggests that poor oral health of women during pregnancy negatively impacts health outcomes for both the mother and baby. Early childhood caries is a significant issue in Victoria, Australia, with almost half of all six-year-old children having a history of tooth decay. Poor oral health can negatively affect a child's speech, growth, learning, development, self-esteem, social and psychological wellbeing and influence the development of lifetime habits. Fortunately, oral disease is mostly preventable with appropriate oral hygiene knowledge, skills and practices. Pregnancy is an important time for women to care for their oral health because of the increased susceptibility to periodontal (gum) infection and the links between advanced gum disease and premature birth and low birth weight babies. In addition, poor maternal oral health may lead to adverse impacts upon the unborn child's oral health outcomes such as the transfer of maternal cariogenic bacterial flora to the child [36-37].

Prevention and early detection of oral disease in pregnancy can assist in managing a significant bacterial and inflammatory condition during pregnancy (periodontitis) and reduce the risk of infants developing early childhood caries. Educating pregnant women on the importance of dental care and good oral hygiene practices and the safety of receiving dental treatment during pregnancy is essential. Therefore, internationally research and oral health care and maternity care guidelines have begun to recognize the role of antenatal care providers in promoting the oral health of pregnant women [38-39].

Tooth decay is common amongst children, especially in areas of deprivation. From both a societal and health care perspective, tooth decay is a global problem with wide-ranging negative effects on children, their family and society. Tooth decay, however, is preventable, with appropriate oral health behaviors established in the home-setting in early-childhood providing lifelong protective effects. These evidence-based oral health behaviors for young children include twice daily parental supervised toothbrushing with fluoride toothpaste and limiting

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

sugary foods and drinks. The term “optimal oral health habits” will be used throughout this paper to describe these oral health behaviors. Parents and local communities identify their preference for establishing optimal oral health habits from the outset rather than correcting poor habits at a later stage. To facilitate these optimal oral health habits, preventive programs need to be multi-faceted and provide consistent oral health messages across all professionals involved in early-years care. One key opportunity to provide oral health advice and guidance is when parents bring their child to the dentist [40-42].

Behavioral management techniques derived from pediatric dentistry practice (desensitization, positive-negative reinforcement, tell-show-do) have been used to improve the ability of children with ASDs to receive dental treatment and oral healthcare. This approach is the first attempt in a series of approaches to overcome undesirable behaviors during oral examinations and dental procedures. Behavioral management can be effective for some, but not for every patient. Many children with ASDs still require advanced behavioral guidance techniques, such as protective stabilization, oral sedation, and general anesthesia, to provide dental care. Behavioral approaches are the most common treatment approaches for children with ASDs, and interventions often include the use of visual pedagogy. It is defined as the ability to recognize and understand ideas conveyed through visible actions or images, and it can be used to enable and/or increase specific skills of children. The method involves the use of pictures/imagines either printed on paper or administered through digital tools, such as computers, smartphones, and tablets; such feasible interactive aids are becoming more and more utilized with special needs children. Among the different visual tools available, the Picture Exchange Communication System (PECS) is a frequently used augmentative communication system, in which picture cards are used to teach functional communication to non-verbal or limited speech children. Visual pedagogy protocols foresee the use of sketches and/or videos to repetitively teach children how to perform tooth brushing and which steps they will encounter during oral examinations and preventive and/or restorative treatments. The core of visual pedagogy is that children with ASDs become familiar with the storytelling that they will remember when in the dental office. A high number of studies have already been carried out on this approach, proving this to be effective in reducing anxiety and increasing compliance [43-45].

Various sources of oral hygiene knowledge, including television, schools, and dental clinics, have been reported to be associated with oral hygiene behavior. We previously conducted a cross-sectional study to investigate the associations between oral hygiene knowledge, the source of that knowledge, and oral hygiene behavior in a group of new university students. The results suggested that having better oral hygiene knowledge, as well as having dental clinics as the most common source of oral hygiene knowledge, were associated with better oral hygiene behavior. Thus, when university students have oral hygiene knowledge from dental clinics, they may improve oral hygiene behavior [46-47].

Dental treatment during pregnancy has been recommended by systematic reviews and several institutions, with guidelines on oral health care during pregnancy being widely available. Such recommendations are important to assure women’s well-being during their lifetime and to control the changes that occur in their oral health during pregnancy, since this condition can increase the prevalence of oral diseases. It is also relevant to determine the relationship between pregnant women’s oral health and negative outcomes that can occur during and after delivery. Moreover, pregnancy is considered an ideal time to establish educational and preventive

programs, as pregnant women are more receptive to information about themselves and their babies' wellbeing and to adopt better health practices [48-49].

Effective oral hygiene measures carried out on a regular basis are vital to maintain good oral health. One-to-one oral hygiene advice (OHA) within the dental setting is often provided as a means to motivate individuals and to help achieve improved levels of oral health. However, it is unclear if one-to-one OHA in a dental setting is effective in improving oral health and what method(s) might be most effective and efficient [50-51].

The well-being of the oral cavity is an integral part of the general state of health of the individual: unfortunately, the increase in world population, and its general aging, has led to an increase in untreated oral diseases. Periodontal disease and dental caries are the most widely diffused pathology worldwide: it has been recognized that dental hygiene-therapists could play a role in the diagnosis of these two pathologies, and that their role could be implemented, for example, in public health services, as a support for patients during their hospitalization. The little concern that does exist in the literature for the oral health of hospitalized patients is limited to intensive care unit wards; attention must be paid to the risk of periodontal disease in patients admitted to this ward, as well as to patients in need of mechanical ventilation, where different bacterial colonization develops. Oral care can prevent plaque build-up, and, consequently, reduce the risk of hospital infections related to a low priority of oral hygiene and/or fear of feeling pain; it is important to note that oral care does not bring any benefits, and hospital staff are often poorly trained. Some studies, to prevent possible bacterial outbreaks, have found a good efficacy of solutions containing 0.12% chlorhexidine, accompanied by a good brushing of the teeth and washing with iodine solutions; in this sense, the nursing staff plays an important role in the maintenance of oral health, and, for this reason, it is beneficial if staffs are effectively instructed by professionals, such as dental hygienists. Furthermore, taking into account the fact that the accumulation of biofilms promotes the development of gingival inflammation, caries, and periodontal disease, and that these worsen during long periods of hospitalization, motivation and education plans should be developed for hospital staff, patients, and caregivers. The oral cavity is a reservoir for pathogens, and accurate oral hygiene, preceded by the screening and removal of potential bacterial foci, can help in managing infections in hospitalized patients. These are patients who can hardly take care of themselves, and therefore trust others for hygienic care, such as oral hygiene maintenance: dental hygienists could be the missing link to help the medical and nursing staff manage the health of these patients [52-53].

Adolescence is a critical period for health promotion. Evidence has shown that relatively stable patterns of health-related behaviors are established during adolescence and it is difficult to change these behaviors during adulthood. To improve oral health, it is necessary to focus on adolescents, as proper personal oral hygiene and eating habits are developed during this stage of life. Evidence indicates that adolescents with favorable oral health habits have better oral health as an adult than those with poorer oral health habits. Consequently, targeting adolescents when promoting oral health can be beneficial.

For school-aged children, school-based settings are more common and effective at providing preventive care than a community-based approach. School-based oral health education (OHE) has been applied successfully in some developing countries to achieve better oral health behavior and dental hygiene status of adolescents at a low cost [54-55].

Multiple medical treatments, associated with the great variability of commercially available drugs, the continuous evolution of scientific research, the advent of procedures for the treatment of pain, modern drugs for the management of thromboembolic risk, and antibiotic resistance, are elements which it is necessary to respond to with absolute knowledge, training, and basic preparation, to meet the rehabilitation needs in the dental field. For this reason, it is important to provide the clinician, in daily clinical practice, with theoretical and practical support to manage the most common framework of systemic pathology of dental interest, including emergencies, as well as knowledge of prescriptions and the behavior of the most common drugs [56-57].

Poorly controlled diabetes affects periodontal outcomes and periodontitis also adversely affects blood glucose levels and worsens diabetes complications. The biological mechanism that links diabetes and periodontitis involves a complex interaction and that includes aspects of inflammation, immune functioning, neutrophil activity, and cytokine biology. The evidence supports that uncontrolled diabetes causes to elevate levels of several pro-inflammatory mediators and cytokines in saliva and gingival crevicular fluid (GCF), oxidative stress in periodontal tissues and formation of Advanced Glycation Endproducts (AGE). Furthermore, the interaction of AGE– Receptor for Advanced Glycation Endproducts (RAGE) exaggerates inflammatory response (inflammatory dysfunction, cellular stress and other changes to important periodontal cells) and leads to periodontal tissue destruction. Although evidence supports for a negative impact of periodontitis on diabetes control and outcomes, there is lack of mechanistic studies to explain its biological plausibility. However, potential factors include the mediators derived from periodontal disease (Interleukin (IL)-6 tumour necrosis factor (TNF)- α , and C-reactive protein (CRP) as well as oxygen radical) which impair insulin signalling and resistance [58-59].

There is also evidence that treatment of periodontal disease has beneficial effects on glycemic control, with a reduction of glycated hemoglobin (HbA1c), although this evidence is often considered of low quality due to the heterogeneity of the studies and small sample size. Recognizing the bidirectional link between diabetes and periodontal disease, as well as potential benefits of periodontal treatment, current guidelines recommend that patients with diabetes optimize oral hygiene behaviors and seek regular oral health check-ups to prevent periodontal disease and maintain good oral health status. Similarly, research indicates that improving oral health knowledge is essential for improving self-oral care practices [60-61].

The need for correct oral hygiene in pregnant patients is essential during the first trimester to prevent possible oral complications; the use of an electric toothbrush can reduce the Plaque Index and prevent strong gingivitis. Patients must be treated without stress, kept in a sitting position, and allowed to often change their position. In addition, pregnant patients often experience nausea and vomiting, as well as gastroesophageal reflux; therefore, it is good to motivate patients by providing instructions on both food and the use of fluoride toothpastes, to prevent the risk of caries. Subjects with coagulation disorders require medical advice before undergoing dental interventions that could cause bleeding. Hemophilic patients should be given clotting factors before, during, and after a dental extraction, or conservative dentistry that requires local anesthesia (for example, fillings); therefore, correct oral hygiene could help in avoiding dental procedures. Oncological patients should start dental treatments before the beginning of cancer therapy; professional oral hygiene, the extraction of compromised teeth, and restorations of teeth with wide caries are recommended. At bedtime, it is advisable to use

TeMALab

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

an electric toothbrush and floss. In diabetic patients, evaluation of their periodontal state is needed, and it is influenced by high serum levels of HbA1c. In addition, hyperglycemia causes a thickening of the basal membrane of the capillaries, resulting in a worsening of permeability and perfusion to tissues, oxygenation, and elimination of metabolites from periodontal tissues. These patients may also have xerostomia, acetonemic halitosis, or hyperplastic gingivitis. Periodontal disease is more aggressive and faster in cardiopathic subjects; moreover, maintaining a balanced oral microbiome is particularly recommended, as it can reduce the complications of cardiovascular diseases. In fact, in the presence of valvular heart diseases and valvular implants, there is a greater risk of endocarditis from the migration of oral bacteria [62-63].

Oral diseases directly impact the lives of individuals by causing considerable pain and suffering, altering food choices, affecting speech, self-esteem, quality of life, and participation in everyday activities. Measuring the impact of oral diseases has traditionally been based upon the biomedical model that provides only limited insight into the impact of oral disease on people's lives. The emerging patient-centered care model⁴ necessitates a focus on oral health rather than oral disease. Although measures of oral health and oral health-related quality of life have been developed, they have not been shown to be useful in all of the important domains of clinical practice, health services research, epidemiology and advocacy. This is reflected in recent definitions of oral health that now include physical, psychological, emotional and social domains, which are core to overall health and wellbeing. From the patient-centered care perspective, oral healthcare providers should thus consider not only disease processes, but also the environmental, social and personal factors, overall quality of life and participation in all major life areas, including making decisions about and control over their health and the use of health services [64-65].

The WHO Operational Framework for Primary Health Care provides definitions for both primary care and primary healthcare. Primary care being defined as 'a key process in the health system that supports first-contact, accessible, continued, comprehensive and coordinated patient-focused care;' and primary healthcare defined as 'whole-of-society approach to health that aims to maximise the level and distribution of health and well-being through three components: (A) primary care and essential public health functions as the core of integrated health services; (B) multisectoral policy and action; and (C) empowered people and communities.' (WHO and the UNICEF, p. XIII). The conceptual basis for this review is situated in primary healthcare as an approach to improving oral health outcomes and reducing the global burden of oral diseases [66-67].

An integration strategy may refer to any activity or intervention (or combination of activities) whose purpose is to, directly or indirectly, support the inclusion of oral health in primary care. These activities could include (but are not limited to) policies, guidelines, frameworks, funding mechanisms and insurance schemes, interprofessional training and education, interprofessional practice, common performance indicators and establishing local or international networks to support the integration agenda [68-69].

Health care is organized in different ways to address these disparities depending on the political and administrative systems in the region. Workforce skill and mix, provision of public health and primary care services, geographic remoteness and service models for indigenous populations, all have a substantial influence on the effectiveness and efficiency of the

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

indigenous health care systems. For some time, an innovative program to train dental therapists has addressed the need to provide better primary dental care [70-71].

Proper oral health behavior such as tooth brushing, use of dental floss and receiving regular dental checkups prevents periodontal disease. Furthermore, oral health behavior is also associated with various factors including dental knowledge, attitude, lifestyle, stress, education level, socioeconomic status, sense of coherence and self-efficacy. Among these factors, we focused on dental knowledge in a previous study and found that university students with dental knowledge practiced better oral health behavior such as use of dental floss.

Diagnosis refers to the identification of a disease based on the presentation of signs and symptoms. Health care professionals in all fields use diagnosis as a means to identify and discuss diseases with patients and formulate a plan for treatment. Dental hygienists incorporate diagnosis, specifically called dental hygiene diagnosis (DHDx), into clinical practice to assist in the prevention and treatment of oral diseases [72-73].

The demographic transition towards ageing societies and the related health burden have triggered a global focus on ageing and health and a fundamental shift in how we think about ageing, bringing forward the concepts of functional ability and participation in society. In oral health, an epidemiologic transition has further compounded the impact of the demographic transition, with profound implications for the burden of oral conditions on older populations. Oral diseases are one of the most prevalent health conditions globally, and their burden, especially tooth loss, is huge amongst the older population [74-75].

Oral diseases pose a significant public health challenge, especially among children and adolescents. Around 60–90% of school children worldwide suffered from caries and over 531 million children had caries of deciduous teeth. Moreover, most children and adolescents showed gingivitis symptoms. Approximately 2% of youth had aggressive periodontitis, which might lead to premature tooth loss. Oral diseases can negatively affect the quality of life, cause pain, limitation in oral functions, impaired nutrition, emotional stress, low self-esteem, and poor school attendance and performance. They also impose a considerable economic burden as oral health treatments are often expensive. The treatment cost of dental caries alone for children was estimated to surpass the total budget of healthcare for children in low-income countries [76-77].

One of the efforts to improve the oral health of children and adolescents is by implementing school-based oral health promotion programmes, as proposed by the World Health Organisation (WHO). Schools serve as ideal settings for health promotion as they can reach most school-aged children and provide important networks to their families and communities. School-based programs can also help increase children's access to dental services, especially those from disadvantaged socio-economic backgrounds. Moreover, school years cover the life period of childhood and adolescence, during which lifelong sustainable behaviors, beliefs, and attitudes related to health are established.

Several school-based oral health promotion programs have been proposed, such as oral health education (OHE), tooth-brushing activities, the provision of fissure sealant, or other treatments. While the effectiveness of the programs has been investigated, extensive evidence from a global viewpoint is still limited. Moreover, existing systematic reviews only focused on OHE. A study providing a complete picture of the effectiveness of different kinds of oral health programs at

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

various school settings has not yet been available. This information is necessary to help the development of policies and the allocation of resources [78-79].

Despite the overall improvement of oral health shown by the age-standardized prevalence, the increase in the older population raises the number of people living with oral diseases. When evaluating the burden of oral disease in the older population, it is important to recognize the difference between crude prevalence and age-standardized prevalence. In many countries, the risk of tooth loss has decreased over the past decades due to improved socioeconomic conditions, lifestyle, and medical standards.

Oral health is considered a determinant indicator for the community's general health and wellbeing. Many factors can widely affect the oral health status of the population, among them include socioeconomic factors and health behaviors. The latter is mainly focused on preventive interventions and behaviors and is determined by the level of information and literacy of the community, particularly about the causal factors of dental caries and the effective modes of prevention [80-81].

Health information seeking behavior is considered as any action by individuals through which they want to increase their knowledge or information about a health issue in order to improve their health. People's attitudes and knowledge can incrementally affect their health seeking behaviors. According to Andersen's health behavior model, some individuals' health condition and their perceived consequence of the action or inaction can determine the health seeking behaviors.

Many interventions can be applied to improve the oral health seeking behaviors such as: developing the target population's education and awareness particularly on applying preventive strategies, implementing and developing health financing interventions and insurance packages and creating opportunities for increasing the access of the population for appropriate time and place of seeking oral health caries treatments [82-83].

Considering the relevant literature, online health services are among one of the ways to increase access and potentiality of seeking oral health behaviors. In this regard, emphasized that, although oral and dental health care professionals are defined as the main trusted and reliable sources for seeking information, other sources are commonly used by patients such as online health services. The degree of effectiveness and usefulness of such online information seeking is highly dependent on the health and internet literacy of the population in addition to access to information and communication technology (ICT).

Health seeking behaviors intend to improve ones' health, and in the process, that of the community. Developing online health resources, are necessary, in particular for youth and those in the most literate parts of the population such as the students. Although medical students are among those groups with an appropriate health literacy level and acceptable access to internet for information seeking, it is not clear whether they have a high level of health information seeking behavior or not particularly in a developing country [84-85]. To fill the present gaps and determine the status of online health seeking behavior in the area of oral and dental health, the present study is aimed to determine the attitude of Iranian medical students towards online oral health information seeking and the level of knowledge, attitudes and oral health practices in this area. The present results can inform policymakers to apply more appropriate and applicable plans and interventions to improve the oral health seeking behaviors among the community particularly in the developing contexts with the similar setting.

Oral disease is common and affects overall health profoundly. Dental caries is the most prevalent chronic disease among children in the United States despite decades of public and private initiatives. Oral disease is complex with origins that are biological, psychological, and sociological. Experts agree that an improvement in oral health will come about only if it is addressed in an interprofessional collaborative manner that emphasizes medical-dental integration (MDI).

Oral health care disparities reflect unequal opportunities to be healthy, making disadvantaged groups even more disadvantaged with respect to their oral health; correspondingly, reducing oral health care disparities means giving disadvantaged social groups equal opportunities to be healthy. Pursuing equity in oral health care means pursuing the elimination of oral health care disparities, that is, equal access to available care for equal need, equal utilization for equal need, and equal quality of care for all. While the imperative to eliminate disparities in oral health has long been recognized, the vital role of access to quality oral health care for people who are low-income, uninsured, and/or members of racial/ethnic minority, immigrant, or rural populations has heretofore received insufficient attention in the public health literature. Disparities need to be more fully investigated in all aspects of oral health care, including the allocation of resources for oral health care, the actual receipt (utilization) of oral health care services, the quality of oral health care services, the oral health care workforce, and the financing of oral health care, particularly with respect to the burden of payment on individuals and households [86-87].

The Health Resources and Services Administration (HRSA) synthesized recommendations and considered expert and professional opinions expressed during the Integration of Oral Health Care and Primary Care Practice meetings. The following recommendations serve as guiding principles and provide a framework for the design of a competency-based, interprofessional practice model to integrate oral health and primary care: Apply oral health core clinical competencies within primary care practices to increase oral health care access for safety net populations in the United States. Develop infrastructure that is interoperable and accessible across clinical settings and enhances adoption of the oral health core clinical competencies. The defined, essential elements of the oral health core clinical competencies should be used to inform decision making and measure health outcomes. Modify payment policies to efficiently address the costs of implementing oral health competencies and provide incentives to health care systems and practitioners. Execute programs to develop and evaluate implementation strategies of the oral health core clinical competencies into primary care practice.

Oral health conditions during adolescence During puberty (preadolescence), which lasts from two to four years with an onset that varies by gender, race/ethnicity, and overweight/obesity, growth and maturation of the body and maturation of the brain accelerate, with accompanying emotional, cognitive, and behavioral opportunities and challenges. These physiological changes have a major impact on all areas and functions of the body, including the oral ecosystem.

Oral health conditions during adulthood and older age Over the past decade, an increasing number of children, especially disadvantaged children, have been visiting the dentist, and the gap in rates of oral health care between disadvantaged and advantaged children has been narrowing. In contrast, oral health care utilization for adults has declined during this time period, especially among the poor and uninsured, and in many states the gap in rates of oral health care between disadvantaged and advantaged adults has been widening. Compared with children and older adults, adults are much more likely to face financial barriers to all types of health care, and more people regardless of income, age, or source of dental benefits report

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

financial barriers to dental care than to medical care, prescription drugs, eyeglasses, and mental health care. Since Medicare covers only narrowly defined medically necessary dental procedures and many state Medicaid programs do not cover dental services for adults, adults pay an increasing portion of their dental expenditures out of pocket as they age.

In dental hygienist education, for example, it is essential to provide opportunities for the students to reaffirm professional values and beliefs, including what kind of a dental hygienist they want to become, and to clarify their vision for the future in their education's early stage. In clinical education, dental hygienists and other professionals can assume specific roles within the community of practice through collaborative practice. To encourage group-level socialization, opportunities to meet role models who are active in various situations and internships in a community of practice can be used. It is also important to incorporate into the curriculum supportive methods that internalize the values of the dental hygienist during these social experiences. A multifactorial genetic effect in their etiology is more common in periodontal diseases. A further complication of the relationship between genes, environment and disease is that environmental genetic influences are necessary to maintain periodontal health.

The importance of introducing education and support that promotes professional identity formation in dental hygiene education has been internationally recognized. For example, service-learning exercises and curriculum revisions have been implemented to develop students' attitudes and sense of professional responsibility. However, the overall understanding of the process of dental hygienists' professional identity formation over time, beginning with their first year of study, remains unclear. Clarifying the process of dental hygienists' professional identity formation could provide insight into students' actual perceptions of the nature, tasks, and value system of the profession. Analyzing the discrepancy between their perceptions of the profession of dental hygienist and the learning outcomes expected by their teachers would provide a basis for improving and developing new educational strategies and learning support methods in the future. Therefore, in this study, as a preliminary investigation of dental hygienists' professional identity formation, we examined the changes in their perceptions of the dental hygienist profession during the three years of their undergraduate education.

In health care globally, there has been a focus on person-centered care, which is an individualized, holistic approach to care where the decision making is shared by the clinician and the client, and at times, includes the client's family or caregiver. Instead of viewing the client as a collection of symptoms, person-centered care fosters communication to take into consideration the client's values and goals. Dental hygienists have an ethical responsibility to provide opportunities for patients to make informed decisions about their treatment. Communicating the DHDx to the patients is part of that responsibility.

CONCLUSIONS

The importance of introducing education and support that promotes professional identity formation in dental hygiene education has been internationally recognized. For example, service-learning exercises and curriculum revisions have been implemented to develop students' attitudes and sense of professional responsibility. In addition, epigenetic changes in the environment also affect periodontal health. It is clear that many genetic traits (eg, type and quality of bone around the tooth root) and epigenetic changes in the oral cavity are important

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

factors in determining the host's response to potential injury and conferring periodontal predisposition. The importance of personal oral hygiene for supragingival plaque removal is a central paradigm in periodontal management. Periodic patient extractions are important because dental bacterial biofilm is the most important modifiable risk factor for periodontitis. Therefore, there is strong evidence that mechanical removal of dental biofilm (eg, brushing, flossing) can significantly affect periodontal tissue stability. Good oral hygiene requires highly motivated and trained individuals with adequate manual dexterity, effective cleaning equipment, chemotherapy drugs to remove plaque, and proper oral hygiene instructions. In health care globally, there has been a focus on person-centered care, which is an individualized, holistic approach to care where the decision making is shared by the clinician and the client, and at times, includes the client's family or caregiver. Instead of viewing the client as a collection of symptoms, person-centered care fosters communication to take into consideration the client's values and goals. Dental hygienists have an ethical responsibility to provide opportunities for patients to make informed decisions about their treatment.

ABSTRACT

The main goal of the study was to analyze the peculiarities of pharmacist profession, modern professional challenges, pharmaceutical sciences, education, prospects, innovations and society. The study was a quantitative investigation and analysis of features, characterizations, scope and capacities for pharmacist role in pharmacy, in clinic and in health care sector and pharmaceutical educational summons issues in the twenty-first century by using questionnaires. Were conducted a survey study. The in-depth interview method of the respondents was used in the study. The 7 types of approved questionnaires were used (Respondents were randomly selected): Questionnaire for chief pharmacists: 410 chief pharmacists participated in the study. Questionnaire for patients: 1506 patients participated in the study. Questionnaire for the employed pharmacy faculty-student: 222 employed pharmacy faculty students participated in the study. Questionnaire for health-care specialists: 307 public health specialists participated in the study. Questionnaire for pharmacist specialist, 810 pharmacist specialists participated in the study. Were used methods of systematic, sociological (surveying, questioning), comparative, mathematical-statistical, graphical analysis. The data were processed and analyzed with the SPSS program. Were conducted descriptive statistics and regression analyses to detect an association between variables. Statistical analysis was done in SPSS version 11.0. A Chi-square test was applied to estimate the statistical significance and differences. We defined $p < 0.05$ as significant for all analyses. According to the study results, being healthcare occupational means of to be a member of a group, which is centered on one purpose: serving with a patient to obtain better health. Pharmacist plays the centric role on the delivering of communication to patients and society about using of medicines. They effectively cooperate with doctor prescribers to assure a general treatment to patients by the delivery information and advice. The pharmacists are involved in a multidisciplinary treatment to the contribution the rational pharmacotherapy. They sufficiently informing patients and common society about the adverse influences of the drugs. They are monitoring these side effects via partnership together with different health care vocational. Pharmacists provide education on medications, disease states and the lifestyle issues as a part of clinical prevention, as well as educational programs to groups on issues such as drug abuse or others that are an example of population health activities. Pharmacists do counsel on a wide range of health promotion products found in the typical retail pharmacy such as sunscreens, dental hygiene products or vitamin and mineral products.

1. INTRODUCTION

Pharmaceutical care includes the process through which a pharmacist cooperates with a patient and other medical professional in planning, monitoring, controlling and implementing a therapeutic scheme that will generate concrete therapeutic results for to the patients. This set involves three major functions: identifying potential and actual drug associated issues; resolving actual drug associated problems; and preventing drug associated issues [1-3].

Pharmaceutical care is a needful element of health care system and should be integrated with other basic elements. It is provided for the straight benefit of the patient, and therefore the pharmacist is responsible entirely to the patient for the quality of pharmaceutical care [4-7].

The main relationship in pharmaceutical care is a jointly useful interchange in which the patient grants authority to the provider, and the provider gives competence, ability, capacity, power, capability, and commitment (accept responsibility) to the patient. The vital goals, processes, and relationships of pharmaceutical care exist regardless of practice setting [8-10].

Health care costs increase by annually, the volume of medication takes up a significant segment. Effective medication management and Patient care issues become actual. As a result, functioning of clinical pharmacist as a specialist in public health care system is required of human health protection in the private or public insurance companies' active participation will raise the demand for clinical pharmacist as a specialist in the area. Insurance companies work should be focused on the relationship between the clinic and pharmacy institutions with highly qualified specialists [11-13].

Goal: The main aim of the study was to analyze the scientific talks of manifestation of peculiarities of pharmacist profession, modern professional challenges, pharmaceutical sciences, education, prospects, innovations and society.

2. MATERIAL and METHODS

Research objectives are materials of sociological research: the study was quantitative investigation by using survey (Questionnaire). The study was quantitative investigation by using survey (Questionnaire). The in-depth interview method of the respondents was used in the study. The 7 types of approved questionnaires were used (Respondents were randomly selected): Questionnaire for chief pharmacists: 410 chief pharmacists participated in the study. Questionnaire for patients: 1506 patients (customers of drug-stores) participated in the study. Questionnaire for the employed pharmacy faculty-student: 222 employed pharmacy faculty students participated in the study. Questionnaire for health-care specialists: 307 public health specialists participated in the study. Questionnaire for pharmacist specialist, 810 pharmacist specialists participated in the study.; Totally 3888 respondents were interviewed in Georgia. We used methods of systematic, sociological (surveying, questioning), comparative, segmentation, mathematical-statistical, graphical analysis. The data was processed and analyzed with the SPSS program. Results and discussion: The survey was conducted through the questionnaires. 1506 patients were interviewed in Georgia. Questions and answers are given in the tables. On each question are attached diagrams or table. Questionnaire and diagrams are numbered. Study of the data was processed and analyzed with the SPSS program. We conducted descriptive statistics and regression analyses to detect an association between variables. Statistical analysis was done in SPSS version 11.0. A Chi-square test was applied to estimate the statistical significance and differences. We defined $p < 0.05$ as significant for all

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

analyses. The study's ethical items. In order to provide the study's ethical character each participant of it was informed about the study's goal and suggested of willingness of the work to be done. So, the respondents' written or oral compliance was got on that issue. All the studies were carried out by the selected organizations administrations' previous compliance. Were used Informed consent form for each respondent to participate in an anonymous survey. During the whole period of research, the participants incognita was also provided. For the international rules and criteria' conformity this human subject comprising given study was discussed and confirmed on the Bioethics Committee sessions of the YSMU. In order to meet the objectives, set in the research we also used the results obtained through analysis of available official information, studies and opinions about pharmacists, as well as the methods of quantitative studies. We conducted descriptive statistics and regression analyses to detect an association between variables. Statistical analysis was done in SPSS version 11.0. A Chi-square test was applied to estimate the statistical significance and differences. The research implementation required the following sub studies: the scientific talks of manifestation of peculiarities of pharmacist profession, modern professional challenges, pharmaceutical sciences, education, prospects, innovations and society.

3. RESULTS and DISCUSSION

On the basis of performed study results the following have been found:

The health systems of many other countries have developed similar claims of competence for pharmacists. As a critical care pharmacy specialist, it is difficult to describe a typical day, but usually busy with the elements of a pharmacist's support process during the day. It is believed that the clinical pharmacist will be responsible for all aspects of the administration of the drug. Every day, the clinical pharmacist assesses and evaluates new patients and updates the progress of previous patients, identifies drug-related issues and potential problems, develops a problem list and treatment plan for optimal dosage based on the renal and hepatic function, potential drug interactions and serum concentration. The clinical pharmacist joins the multidisciplinary rounds with the intensive care team and applies the treatment plan by teaching the medical residents the correct order of entry or by entering the orders themselves according to a collaborative practice agreement and by them. documenting in an electronic health record. A major contribution to medication management is identifying therapies that are no longer needed, reducing the cost and risk of adverse events, and supporting antimicrobial stewardship programs with infectious disease physicians and pharmacists. The clinical pharmacist also supervises the performance of quality measures such as the appropriate prevention of venous thromboembolism, the appropriate use of drugs to prevent stress gastritis, the addition of aspirin to increase the levels of troponin associated with I coronary ischemia, and discussing the need for central tubing and urinary catheters. The clinical pharmacist educates the team on drug-related topics and related literature through tours and didactic discussions. A clinical pharmacist is always available for emergencies and resuscitation, and to answer questions related to medication [14-16].

The term "pharmaceutical care" was published in 1990. Many of European countries have tried to explain the meaning of this word. Given the fact that European countries are different pharmaceutical activities and policies of the organization, according to their different visions of the issue.

Pharmaceutical care is the responsible provision of pharmacotherapy for the goal of reaching certain effect that enhance a patient's quality of the life. That results are: treatment of a disease;

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

elimination or decrease of the patient's symptomatology; exciting or slowing of a disease process; or preventing a disease or symptomatology [17-18].

Q-1. What are the issues to which for pharmacists are in need of additional- further regular study or training? (You can indicate several answers)

On the question-What are the issues to which for pharmacists are in need of additional- further regular study or training? (You can indicate several answers) Health-care specialists' 60.9% answer New medications, Health-care specialists' 33.6% answer psychology of communication with customers- consumers (patient), health-care specialists' 64.2% answer issues of pharmacotherapy of certain diseases, health-care specialists' 50.2% answer safety and effectiveness of drugs (medications), health-care specialists' 73% answer pharmacology and pharmacotherapy , health-care specialists' 30.6% answer normative legal regulation of pharmaceutical activity ,health-care specialists' 53.4% answer about drugs (medications) toxicity, health-care specialists' 36.5% answer about drugs (medications) dosage, health care specialists' 35.8% answer about routes of drug administration , health care specialists' 19.9% answer about drug forms , health care specialists' 14% answer about drug design, health care specialists' 40.1% answer about rules of drug administration , health care specialists' 18.6% answer about drugs generic, chemical and brand names, health care specialists' 35.2% answer about selection of (Over-the-counter) OTC drugs, health care specialists' 31.3% answer about cost-effectiveness and cost-benefits of drugs.

Community pharmacists' activity is at the forefront of medical care, working at their own pharmacies or in the private ones. Pharmacist's job is all about helping the public, as they participate in the medicines distribution and offering advice to patients and maintaining their health. Pharmacist work is a very demanding occupation in the world. Pharmacists usually are greatly honorable members of the society. Changes in the role of pharmacist and pharmacy community as a medical supplier accelerate along with the fast-moving environment. Today to offer advanced medical services pharmacies deliver educational information at multiple points of contacts and also to raise awareness of the disease are of great importance. These include over the counter (OTC) and the personal care aisle, a pharmacy counter, specialties publications and pickup areas prescription. These innovations are useful not only for customers' pharmacies but also create opportunities for pharmaceutical marketers, measurable return on investment. The educative center of occupational programs and schemes growingly identifies the necessity for the possibility to use the knowledge obtained via simulation laboratories or experiential studying, which needs corresponding faculties and personnel conditions to satisfy these educational necessities. Innovations in faculties and personnel positions with greater consideration to learning, or practice also include accentuation on the research within the framework of PharmD programs. There is a need to encourage the pharmacy's graduates to encounter that, as well as to conducting PharmD degree programs in postgraduate level masters or doctoral scale in philosophy or promoted scientific basement grants for the pharmaceutical, biomedical, clinical, administrative and other fields of researches in the pharmacy direction [19-20]. In the higher pharmaceutical institutions and academy, the health occupations schooling-education programs should contribute career possibilities for pharmacy faculty post-graduates. Pharmacy schoolmaster must make more energetically engaged at the growth for particular training /educational possibilities to arrange and overlook the newest generation for pharmacy faculty or program personnel positions in higher education institutions. In order to engage pharmacy faculty post-graduates to take part in the scientific research. Pharmaceutical

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

faculty program post-graduate professionals should be supported to research the capacity function and role of various pharmaceutical, medical/health care, academic and educational, research and scientific program schemes for to growth consideration in inter-professional scientific groups upon the health professions formation, teaching and education; which is very significant for the high-quality patient care services [21-22].

Clinical pharmacy and career opportunities, although many clinics across the country participate in international clinical trials, which according to international protocol should have a clinical pharmacist participate, although at this stage such a profession and staff clinics turns out to be general practitioners formally fulfill the functions of a clinical pharmacist, which is confirmed in our survey that a pharmacist is needed to expand the role at Georgia. Clinical pharmacy as the field of pharmacy concerned with the science and practice of rational drug use. With this definition, the possibilities for clinical pharmacists are endless. Many career options are available to pharmacists seeking clinical opportunities in their practice. As a clinical pharmacist, you can provide general clinical services. However, there are several highly specialized areas that cover different patient groups [23-24].

Pharmaceutical supply will be an important new concept, representing the growth of the profession beyond clinical pharmacy as commonly practiced and beyond the other activities of pharmacists, including the preparation and dispensing of medicines. In Europe, however, all these professional activities are important and strongly support the need for pharmacists to be involved. In practice, these activities should be integrated and result in the pharmaceutical care of individual pharmacists for individual patients. The philosophy of pharmaceutical care (PA) is the sum of the pharmacist's responsibilities to meet all of the patient's medication-related needs through direct patient care and collaboration with other facets of the healthcare system. Clinical pharmacists have in-depth therapeutic knowledge and scientific skills that enable them to act as experts in drug therapy in healthcare settings.

Research activities to generate new knowledge and practical skills that can further improve health and quality of life. Over the years, the role of pharmacists has evolved to be part of a multidisciplinary healthcare team, participating in patient advisory groups and reviewing the patient profile with the aim of identifying and resolving drug-related problems. Pharmacist interventions such as B. Patient counselling to improve adherence and compliance, have contributed to the steady development of clinical pharmacy services around the world, the lack of specific legislation and recognition by other healthcare providers [25-26].

Possible reasons may include a lack of acceptance of the pharmacist's professional position by other healthcare professionals, poor leadership skills, patient perceptions, and the existence of communication gaps between pharmacists and physicians. These challenges are particularly noticeable in developing countries. Physician expectations and perceptions about the roles and responsibilities of pharmacists are the main factor influencing the advancement of clinical pharmaceutical services in hospitals [27-28].

Recent reforms to hospital implementation guidelines state that pharmacists should be assigned to hospitals for the benefit of patients. Prioritizing national guidelines, the undergraduate pharmacy curriculum shifted toward patient-centered practice by including a mandatory one-year internship program as part of academic training. Hospital clinical pharmacists began to work as an integral part of healthcare teams. Clinical pharmacists sporadically provided various care services to patients.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

This includes managing drug therapy, dose adjustments, interventions to optimize drug therapy, and providing information about drugs to healthcare professionals and patients. Hospital. A better understanding of the perspectives of healthcare professionals regarding clinical pharmaceutical services may provide a better opportunity to identify future challenges and opportunities for clinical pharmacists in the hospital. Therefore, the present qualitative study aimed to examine the challenges and opportunities of clinical pharmaceutical services provided in the hospital from the perspective of healthcare professionals [29-30].

On the basis of the theoretical and logical analysis the structure and composition of the factors have been developed, considering the objective (external), subjective (internal) and universal factors, which influence on the professional formation of the pharmacist. These factors comprised the content of work, position, correspondence of qualification and nature of work to capabilities, aspirations and inclinations of the pharmacist, the existence of perspective for professional promotion. The existence of perspectives for career promotion, the possibility to enhance qualifications, a high degree of responsibility for the work results, regimen, labor salary and the system of benefits scheme for employees, support and assistance of a manager, direct relations with manager and colleagues serve the essential base for the pharmacists' successful work. The unity of criteria for pharmacist professional formation, for the common professional formation (characteristic to all stages) and the specific professional formation (characteristic to the separate stage) had been developed. A pharmacist's involvement in the development and conduct of a clinical research study of an investigational drug is critical to maintaining the highest standards of drug safety and ultimately the quality, efficacy and safety of the study results. The pharmacist has the potential to act as a consultant in protocol development or review, to support protocol implementation in a facility, and to provide ongoing compliance or audit support. Ultimately, the pharmacist's experience and training in the safe and effective use of medicines translates naturally into the clinical research environment, enabling researchers to conduct clinical trials more safely and competently [31-32].

A clinical pharmacist is in no way a competitor of a doctor, on the contrary, he must refer patients who need qualified medical care to a doctor. It is difficult to imagine that a pharmacist does not know the alphabet of medicine and does not have relevant knowledge of the main clinical syndromes. Must have a particularly good knowledge of the nomenclature of medicines (mainly over-the-counter medicines). In essence, a clinical pharmacist must provide a defined pharmaceutical supply and make a decision about the dispensing of the drug [33-34].

It should be noted that in developed countries and in many developing countries pharmaceutical specialty is regulated profession alike the family medicine. In western countries pharmacist as a family doctor need higher pharmaceutical education, diploma and continuous pharmaceutical education, pharmaceutical license and periodic accreditation. Only pharmacists with higher pharmaceutical education have the right to work as pharmacists' position in the pharmacies. On the pharmacists' certification programs should be only involved pharmacists who have graduated pharmaceutical faculties from state recognized and accredited universities. It is necessary to provide a deep cooperation between pharmacists and physicians on the issues of pharmacotherapy and healthcare to ensure the patients' health state effective improvement, and also to provide the best feedback regulation and revision in the healthcare specialists' team work. Pharmacists also should be responsible for registration of the drugs' side effect, as well as be attentive in case of impropriety and professional defects of drugs they provide. To

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

achieve that it is necessary to raise awareness of specialists on the essence of pharmacists' profession and functions among the medical personnel and general public [35-36].

The clinical pharmacist monitors and evaluates the prescribed pharmacy programs in terms of operational, quality and financial efficiency and regularly compares himself with the best local and national practices; The clinical pharmacist proactively identifies practice issues that need to be assessed and promotes clinical research projects, quality improvement initiatives, or the training of healthcare professionals as needed to advance the practice. Clinical pharmacist develops and oversees policies and procedures for drug procurement, drug use, drug distribution and drug control. The clinical pharmacist ensures that the pharmacy is an integral part of the health care delivery system and contributes to the improvement and expansion of pharmacy services/programs; Provides direct patient care and clinical practice, including decentralized and service-oriented programs; The clinical pharmacist is well versed in decentralized pharmacy services and clinical pharmacy programs; Works as an active member of a multidisciplinary team and collaborates with healthcare providers in decentralized patient care areas to provide patient-centered care; Identifies high-risk patients and implements measures to improve quality and safety; Makes appropriate, evidence-based, patient-centered drug recommendations; The clinical pharmacist is involved in the management of emergency medical care; Providing a review of medication intake at discharge, approval and counseling as needed; Provides pharmaceutical services throughout the medical center; Owns hospital IT systems and drug ordering systems; Provides accurate, safe, timely and appropriate drug therapy in accordance with the age and needs of the patient; The clinical pharmacist performs critical patient monitoring and reviews the patient profile / chart to identify, prevent, or mitigate drug-related problems, wrong drug or dose selection, sub-therapeutic dose, overdose, drug adverse reactions, drug interactions, drug missing, no indication to treatment, the use of drugs without indications and treatment failure; The clinical pharmacist communicates effectively and appropriately with healthcare providers and caregivers (doctors, nurses, etc.), and ensures the continuity of pharmaceutical care between shifts and between staff; The clinical pharmacist is actively involved in drug management and restriction programs; Participate in the work of pharmacies and distribution of medicines; Clinical Pharmacist maintains competence and actively participates in operations programs, central pharmacies, subsidiary pharmacies and specialty pharmacy areas, as required by the work assignment; Facilitates the process of purchasing, ordering and dispensing specialized drugs, including but not limited to chemotherapy, parenteral nutrition, controlled substances, etc., as appropriate [37-39].

Standard safety practices for investigational drugs in clinical trial protocols are limited and the vast majority of research pharmacists have safety concerns. Identified drug safety risk areas include protocol complexity, drug ordering, and processes involved in packaging, storage and distribution of investigational medicinal products. Pharmacist involvement creates several mechanisms to improve the safety and quality of clinical research. This is accomplished by participating in the development of the study protocol, reviewing as a member of the advisory committee, developing mechanisms to promote safety, and ensuring compliance with local and national regulations and standards. Ultimately, the pharmaceutical profession has a fundamental responsibility to ensure the safe and effective use of drugs, including investigational drugs, in clinical trials. Through interdisciplinary collaboration, the research study achieves the highest safety standards and maximizes the quality and efficiency of the data obtained during the clinical study [40-41].

September 14-15, 2023, Naples, Italy

Responsible administering of drugs involves that healthcare network mediator capabilities and activities are balanced to assure that patients get the right drug, on the proper time, using properly and patient have profited from them. Delivering the right drugs into patients' demands commitment of all representatives, inclusive Government and a desire on how to consolidate private and public interests and mobilize sources. That is significant for the public to be guaranteed that expenses on pharmaceuticals productions are an equivalent cost of cash. On the viewpoint of the pharmacists' comprehensive academically field and their traditionary function in composing, qualifying, delivering and ensuring drugs. A pharmacist is informing customers, consumers and patients on the drug using; they are greatly positioned to suppose professional liability for the monitoring of pharmacotherapy. They are members of the healthcare team immediately engaged in patients' health care services. Their responsibility is to assistance patients in using their drugs, which is impossible to do alone. Thus, in terms pharmacists' profession have been progressed. New type pharmacists have done the work a in more efficient way. Pharmacists holding the higher, university-level education. They understand the biochemical mechanisms of metabolism, mechanisms actions of drugs, medicines pharmacotherapeutic characteristic, side effects of drugs, potential interactions of drug and the argumentations monitoring. It is conjugated of specialized knowledge of biochemistry, anatomy, therapy, physiology, pathology, pharmacology and other pharmacy subjects. The pharmacists explain this particularized knowing when communicating with physicians, patients and another health care providers [42-43].

Being healthcare occupational means of to be a member of a group, which is centered on one purpose: serving with a patient to obtain better health. Pharmacist plays the centric role on the delivering of communication to patients and society about using of medicines. They effectively cooperate with doctor prescribers to assure a general treatment to patients by the delivery information and advice. The pharmacists are involved in a multidisciplinary treatment to the contribution the rational pharmacotherapy. They sufficiently informing patients and common society about the adverse influences of the drugs. They are monitoring these side effects via partnership together with different health care vocational. Pharmacists provide education on medications, disease states and the lifestyle issues as a part of clinical prevention, as well as educational programs to groups on issues such as drug abuse or others that are an example of population health activities. Pharmacists do counsel on a wide range of health promotion products found in the typical retail pharmacy such as sunscreens, dental hygiene products or vitamin and mineral products. Moreover, pharmacists provide immunization services and participate in screening activities [44-45].

Though the quantity of pharmaceutical productions on the world market is growing, the approach of vital medicines is till now lacking in a lot of parts of the worldwide. Health care expenses rise and the technological, social, political and economic conditions change have made the health care transformation crucial across the worldwide. The renewed treatments are required reforms at the personal and public levels to ensure effectively, quality and safe pharmacotherapy to the patients in more ever complicated surroundings condition [46-47].

The pharmacists hold the great condition to satisfy the necessity for health care vocational to ensure effective and safe using of medicines. To do this, pharmacists should suppose higher liability than they at the present time do for the monitoring of pharmacotherapy for the customers, consumers and patients they are serving. That liability goes completely behind the traditional distributing and dispensing practices that have long been the maintenance of

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

pharmacy activities. Pharmacists' liability should be enlarged conclude controlling of the pharmacotherapeutic progression and thereby improve therapeutic outcomes and patients' life quality, advising with doctor prescribers and consolidating with different health care workers and practitioners on behalf of patients [30]. Pharmacists' involvement into pharmaceuticals may consist in drug storage, drug supply, dispensing, manufacturing, formulation, distribution, marketing, quality warranty, licensing, information management, monitoring, development, education, and research. Drug supply and medicine information management system is the main part of pharmaceutical services and proceeds forming the basement of pharmacy activities. The higher pharmaceutical schooling and education hold an appropriate duty and responsibility to generate post-graduate professionals who are qualified and authorized to provide the pharmaceutical care services. Sufficiency results promote to quality warranty by provided that easily approachable working standards [48-49].

A large majority of respondents' (pharmacists) consider that the Government should make the certification of pharmacists. As revealed, it is very important that the occupation of pharmacist should become regulated health profession. To raise pharmacists' specialists' professionalism, Government should make the certification of higher pharmaceutical education pharmacists. That is very essential for pharmacist's professional perfection, for successful higher pharmaceutical education, for pharmacist self-realization, for pharmacist's career advancement, for to exist pharmaceutical continuous professional education, for pharmacist professional growth, for pharmacist job gratification, for pharmacist career satisfaction, for pharmacists much higher status between health care specialists. Pharmacist certification is essential for pharmacists economic (material) welfare, for allows pharmacists to realize fully the received knowledge from higher education institution in work by the full extent, for to have private pharmaceutical activity, for pharmacists vocational development, for correspondence of pharmacist qualification to work, for further improvement perspective for pharmacists' professional promotion, for possibility to career enhancement strategy, for to realize by the full extent pharmacist professional capabilities, skills and habits, for occupational growth, for pharmacists professional satisfaction, for career enhancement perspective, for satisfaction of income (salary). Therefore, pharmacists' certification should start immediately and pharmacist vocation should become regulated health profession like family doctors.

The majority of the respondents (chief pharmacists) considered that main qualities, capabilities and skills required for pharmacists were ability to make decision fast and love towards their profession.

Less than half part of chief pharmacists considered that main qualities, capabilities and skills required for pharmacists were flexibility while changing the labor functions, ability to build up relations with people and high level of culture.

Therefore, the role of pharmacist is underlined in healthcare system. For the higher quality healthcare and pharmaceutical services education level is of great matter. The study provided showed that the health of patients was directly related to the professional education level of pharmacist. Therefore, pharmacist should have appropriate higher pharmaceutical education, higher professional knowledge in pharmacology, pharmaceutical care, pharmacotherapy, clinical pharmacy and other professional subjects.

For the majority of respondents' patients mostly asked the pharmacists about the rules of drugs intake and prices of drugs. For the less than half part of the respondents mostly asked about the

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

drugs' adverse effects and quality. For about the one third of them mostly asked about help in selection of analogue of drugs, indication/contraindication of drugs, the terms and conditions of their storage (conditions and shelf-life), the drugs dosage, rules of drug administration and selection of OTC drugs.

Therefore, pharmacist should possess deep and steady knowledge in pharmacology, pharmacotherapy, toxicology, pharmaceutical care, clinical pharmacy, pharmacokinetics, pharmacodynamics, basics of medicine and other pre-clinical and clinical subjects. Such knowledge can be obtained only from higher pharmaceutical education institutions. Therefore, pharmacist working on pharmacist position must have exclusively the higher pharmaceutical education.

The respondents' -public health specialists' majority considered that the pharmacists' functions in a pharmacy consisted in realization of drugs and instruments of medical purpose and providing information about drugs to the population. Less than half part of the respondents considered it to be in ultimate care about the patients' health and wellness, the drugs dosage and dispensing. About one third part of the public health specialists considered it to be in creation, development, production and sale of drugs, medical devices, instruments for medical purposes and healthcare products. About one third of the health specialists considered the pharmacists to be experts of drugs; about one third of them – to be inform of customers in cost-effectiveness and cost-benefits of drugs, the rest part of them considered that pharmacists help in selection of analogue of drugs. According to that pharmacist job should become regulated and more authorized in health care system.

The respondents' public health specialists' majority considered that the pharmacists' functions in a pharmacy consisted in realization of drugs and instruments of medical purpose and providing information about drugs to the population. Less than half part of the respondents considered it to be in ultimate care about the patients' health and wellness, the drugs dosage and dispensing. About one third part of the public health specialists considered it to be in creation, development, production and sale of drugs, medical devices, instruments for medical purposes and healthcare products. About one third of the health specialists considered the pharmacists to be experts of drugs; about one third of them – to be inform of customers in cost-effectiveness and cost-benefits of drugs, the rest part of them considered that pharmacists help in selection of analogue of drugs. According to that pharmacist job should become regulated and more authorized in health care system.

The respondents' public health specialists' majority considered that importance in work of pharmacist was in personal realization as a specialist, receiving remuneration and provision of necessities of life. The respondents' minority considered it to be in relief of pain in suffering of people.

Less than half part of the respondents' public health specialists considered that the level of basic training of pharmacists was not corresponding to the contemporary requirements. According to the sociological study results of the public care specialists it is obviously, that all pharmacists should have higher pharmaceutical education from the state recognized and accredited higher education institutions and universities. Pharmacists' specialty should become a regulated health care profession. According to that Government should make certification, licensing and accreditation of pharmacist professionals.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

The respondents' public health specialists' vast majority considered that the issues to for pharmacists were in need of the further regular studies or trainings in the following fields: new medications, issues of pharmacotherapy of certain diseases, pharmacology and pharmacotherapy, drugs toxicity. From the study results it is obvious that in the higher pharmaceutical institutions' pharmaceutical educational programs and curriculum need upgrade, renewal, modernization and adaptation to the new modern medical challenges. Therefore, continuous pharmaceutical educational programs should be created. These programs should be more focused on new medications, pharmacotherapy, drugs toxicity and dosage, routes of drug administration, selection of OTC drugs, cost-effectiveness and cost-benefits of drugs.

Approximately half part of the respondents' public health specialists was not familiar to the concept of pharmaceutical care; while more than a quarter of the public health specialists were well familiar to the concept of pharmaceutical care.

The respondents' public health specialists' large majority considered necessity of provision of cooperation between pharmacists and physicians on the issues of pharmacotherapy. The pharmacist must provide information to doctor about new drugs pharmacotherapy, the generic replacement drugs, the cost-effectiveness and cost-benefits of drugs, drugs' generic, chemical and brand names. In our opinion and vision cooperation between pharmacists and physicians on the issues of pharmacotherapy is positively reflected on patients' health and has great importance for provision higher quality health care service for patients' safety.

More than half part of the respondents' public health specialists considered that pharmacist is not in charge of treatment as a physician, meanwhile about a quarter of the public health specialists considered a pharmacist to be in charge of that. Properly educated pharmacist can minimize and reduce the mistakes made by a doctor in the recipe. That has a great importance and value for provision higher quality health care service for patients' safety.

The respondents' public health specialists' vast majority considered that pharmacist should provide assistance in teaching patients to understand the prescribed drugs intake rules. According to that higher quality pharmaceutical service could be only provided by the pharmacists of higher pharmaceutical education, graduated from the authorized, accredited and licensed by the state higher education institutes and universities.

To provide contribution and assistance in teaching of patients to understand the prescribed drugs intake rules, pharmacists need in deep knowledge in basics of medicine, pharmacology, pharmacotherapy, pharmaceutical chemistry, pharmaceutical care, clinical pharmacy and other pharmaceutical disciplines. Properly educated pharmacists have great importance and value for the provision higher quality health care services, for the provision higher quality pharmaceutical care and very essential for patient's safety.

About half part of the respondents' public health specialists considered that pharmacist is not responsible for registration of adverse effects of the drugs, while less than a third part of them considered pharmacist to be responsible for that. By legislation one of the functions of pharmacist is to register the side effects of drugs, what is very essential for patients' safety. It should increase the awareness of pharmacist as the health professional.

The respondents' public health specialists' vast majority considered that the Government should make the certification of pharmacists. It is very essential and important that higher

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

pharmaceutical educated pharmacists to have pharmacist license issued by the Government. The vast majority of the public health specialists considered that the professional activity of pharmacist is very important for the society.

For the majority of respondents mostly significant factors while choosing a pharmacy were: service culture, wide range of products and reasonable prices. For less than half part of respondents mostly significant factors while choosing a pharmacy were: possibility to receive consultation about medications with a physician/ a pharmacist, convenient location of the pharmacy, high qualification of pharmacist personnel.

During research the factors, influencing on the pharmacy faculty students' professional development were found and evaluated. These factors included interesting and valuable work, the favorable psychological climate within the colleagues' team, possibility of career development, professional training, social importance of profession and independence in the work.

The employed pharmacy faculty students' vast majority considered that the Government should make the certification of pharmacists to raise professional standards licensing and certification of pharmacists. The certification of higher pharmaceutical education pharmacists is very essential for the pharmacist's professional perfection, for pharmacists' career enhancement, for vocational advancement and it is main determine detector factor for pharmacist professionalism level. Pharmacist position should become regulated health profession as the member of other health profession team (but now unfortunately pharmacists are not member of regulated health teams). Pharmacists' periodic licensing, certification and accreditation should increase pharmacists' professionalism level and is guarantee upper quality pharmaceutical care. All above mentioned is indicator factor of the health care system service quality.

First time were complex studied professional peculiarities of the pharmacists per vision by pharmacists specialists, professional peculiarities of the employed pharmacist-student, professional peculiarities of the pharmacists by vision of the chief -pharmacist, peculiarities of professional for pharmacists via per vision of the health-care specialist, pharmacists' professional features as per view of the patients, professional peculiarities of the young pharmacist- specialists, professional peculiarities of the pharmacist-student. To reveals influencing factors for the specificities of the role, achievements, innovations, professional and enhancement prospects of pharmacists in health care sector. In result of the study and evaluation of the pharmacist's professional peculiarities news, objectively reasoned comprehension of the problems in this field has been adopted, which became a base for developing recommendations. In particular, for the first time the following have been studied and established: the peculiarities of professional and career improvement strategy for pharmacists, pharmacist specialist's professional features, specificities of the role, achievements, innovations, professional and enhancement prospects of pharmacists in health care sector globally. First time the process of professional formation of pharmacists in the scope and context of pharmaceutical care, including the stages of professional development was studied and scientifically established. First time the most influence factors for the pharmacist's professional formation were identified. Deepen defined the role of pharmacist and the specific features for the pharmaceutical specialists' formation at various stages were studied and identified. On the bases of comprehensive studied was revealed, that pharmacist specialists in contradistinction to other medical specialists like physicians, dentists etc do not have continuous education,

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

periodic certification and licensing. Pharmacists' profession removed from the regulated and certified health professional members' team.

The results of our study have been shown and substantiated, that the pharmacists, as well as doctors and stomatologists, who are obliged to take part in the mandatory certification by the Government, in order to improve the responsibility on their own professional specialization for motivate and improve their vocational knowledge and skills with the help of continuous education.

It would be promoted, that pharmacist to become more responsible, accountable and liable on for enhance their professional knowledge, skills and competencies. All the above mentioned first time we conducted a comprehensive and deep study of the scientific research for specificities of the role, achievements, innovations, professional and enhancement prospects of pharmacists in health care sector globally.

A little less than a fifth of higher pharmaceutical education pharmacists have realized professional capabilities, skills and habits to the full extent, A little bit less than half of higher pharmaceutical education pharmacists have realized professional capabilities, skills and habits partially, more than 50% of own potential, about a quarter of higher pharmaceutical education pharmacists have realized professional capabilities, skills and habits - partially, less than 50% of own potential . At the same time the vast majority of the pharmacists and health care specialists noted that pharmacists' knowledge in disciplines, such as the pharmacology, pharmacotherapy, pharmaceutical care and clinical pharmacy were a lack of insufficient for the successful work. Health care specialists' vast majority think that pharmacists are in need of additional- further regular study in the above-mentioned directions. Approximately half of the respondents considered that just 50% of their own potential was realized at the work position. Anyway, the overwhelming majority of the young pharmacists would not like to leave their profession. The vast majority of young pharmacist specialists consider that in pharmacology, in pharmacotherapy, in pharmaceutical care, in clinical pharmacy their knowledge is a lack or is not enough for successful work [27-29].

The vast majority of the pharmacists (84.4%) considered that for full pharmaceutical activity it is necessary to provide continuous professional education; therefore, higher pharmaceutical education pharmacists consider that professional education should not be ceased. The vast majority of pharmacy faculty students consider that education should not be ceased. Pharmacy faculty students' more than a third was working by specialty. The huge part of the pharmacists (55.6%) considers the continuous professional education is essential for the career growth and professional development, which enables getting information of new drugs and updated knowledge of some diseases' pharmacotherapy, pharmacology and the pharmaceutical care. At the same time, the minority of respondent pharmacists (8%) had not used knowledge obtained from the professional publications and literature in their practice, while less than half of them (41%) had partially used. Competent pharmacist specialist who is capable of providing qualified pharmaceutical care (assistance) is formed in the professional training process.

A large majority of chief pharmacists (76.6%), vast majority of patients (82.6%), of the vast majority of the employed pharmacy students (95.9%), the large majority of the healthcare specialists (94.8%) and a big majority of pharmacists (71.9%) considered that the Government should imply the pharmacists' certification in the way acting for other medical specialists. That

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

is very essential for pharmacists' professional perfection, for self-realization, for career advancement, for continuous professional education, for professional growth.

The necessity of pharmacists' certification was stated more often by employed students than by pharmacists (Chi-square = 57.3, $p < 0.001$). Statistically significant was association between patients' educational level and their opinion about the necessity of pharmacists' certification ($p < 0.04$): patients with higher education considered certification of pharmacists as mandatory more often than did patients with secondary education. Chi-square test of independence revealed that pharmacists more often than students mentioned mission (the desire to obtain a profession in compliance of own trends, aspirations and inclinations, personal desire, specialty love from childhood) as the main motive of their professional choice (65.5% versus 55.8%). Difference was statistically significant with Chi-square=9.9, $p < 0.002$. The difference between pharmacists and young specialists and young specialists and students wasn't statistically significant. Chi-square test of independent has been performed in order to compare the attitude of different sides to the necessity of pharmacists' certification regulation by Government. Opinion that certification of pharmacists should be mandatory was more common among health care specialists than among chiefs (Chi-square = 45.2, $p < 0.001$) and among pharmacists (Chi-square = 68.9, $p < 0.001$), but the there was no statistically significant difference between chiefs and pharmacists. It was more common also among patients /patients than in pharmacists (Chi-square = 44.2, $p < 0.001$).

Q-2. Are you satisfied with your professional (occupational) choice? Are you satisfied with your profession? On the question-are you satisfied with your professional (occupational) choice? Are you satisfied with your profession? Pharmacist' 57.7% satisfied with professional (occupational) choice, pharmacist' 25.3% partially satisfied with professional (occupational) choice, pharmacists' 4.4% have doubts with professional (occupational) choice, pharmacists' 6% disappointed with professional (occupational) choice, pharmacists' 6.5% not satisfied with professional (occupational) choice. See Illustration 1.

Illustration 1. Satisfaction of professional choice of respondents. (Source – study results).

The purpose of the clinical pharmacy statement is to help pharmacists understand pharmaceutical care aspects deeply. Such understanding must precede efforts to implement pharmaceutical care, which is a top priority in all practices. Many pharmacists have embraced the concept of pharmaceutical supply with enthusiasm, but there has also been significant inconsistency in the way it has been described. Directly in the clinical environment, there are

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

many goals and tasks that clinical pharmacists can fulfill. The clinical pharmacists work in almost of medical institutions, which contributes to the rational use of drugs and saves drugs. The involvement of a clinical pharmacist is important at all stages of creating a treatment algorithm. A clinical pharmacist is required to participate in the development of a drug use policy, collaborate with specialists in the development of methodological recommendations and guides for the treatment of specific diseases, participation in the sale of drugs and the manufacture of drug formulations in processes and delivering high quality pharmaceutical care services. The structure and composition of the factors has been developed, which taking into account the objective (external), subjective (internal) and universal factors, which effects on the professional formation of the pharmacist. Developed the unity of criteria for pharmacist professional formation, criteria for common professional formation (Characteristic for all stages) and criteria for specific professional formation (characterized for separate stage).

Q-3. Estimate the impact factors, which have influence on your work satisfaction under 5-point scale (system) (estimate each factor). Report on the question - Estimate the impact factors, which have influence on your work satisfaction under 5- point scale (system) (estimate each factor) See Illustration 6 and See Table 1.

Illustration 1. Report of impact factors, which have influenced on respondents work satisfaction, estimated under 5- point scale (system) (Source – study results).

Only pharmacists with higher pharmaceutical education have the right to work as pharmacists' position in the pharmacies. On the pharmacists' certification programs should be only involved pharmacists who have graduated pharmaceutical faculties from state recognized and accredited universities. It is necessary to provide a deep cooperation between pharmacists and physicians on the issues of pharmacotherapy and healthcare to ensure the patients' health state effective improvement, and also to provide the best feedback regulation and revision in the healthcare

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

specialists' team work. Pharmacists also should be responsible for registration of the drugs' side effect, as well as be attentive in case of imperfection and professional defects of drugs they provide. To achieve that it is necessary to raise awareness of specialists on the essence of pharmacists' profession and functions among the medical personnel and general public.

Pharmacists have main role in the drug dispensing processing, pharmacists receive extensive training and are considered experts in various aspects of drug therapy. Therefore, pharmacists are the best sources of drug information. This is particularly important in the context of investigational drugs, where traditional information resources may not be available. The pharmacist plays an important role in ensuring that all parties involved in dispensing, administration, and other supporting roles in the investigational process are trained in the administration of the investigational drug. Pharmacists provide this education by publishing local drug information leaflets that describe important aspects of the drug and how to use it correctly. This document contains a lot of information that may be useful in various real-world research environments. Asking the pharmacist to condense the information into a central, concise document saves time and effort when the information is needed. A complete document should begin with the drug name, all synonyms and abbreviations, and basic pharmacological information. This concerns the mechanism of action and pharmacokinetic parameters. This information may be particularly useful in determining whether side effects experienced during the study may be related to the study drug. Additionally, it should include dosage ranges, treatment regimens, contraindications, monitoring parameters, as well as information on preparation and administration. Additional information on toxicity and how to handle drug interactions may also be included.

4. CONCLUSION

Community pharmacists' activity is at the forefront of medical care, working at their own pharmacies or in the private ones. Pharmacist's job is all about helping the public, as they participate in the medicines distribution and offering advice to patients and maintaining their health. Pharmacist work is a very demanding occupation in the world. Pharmacists usually are greatly honorable members of the society.

Changes in the role of pharmacist and pharmacy community as a medical supplier accelerate along with the fast-moving environment. Today to offer advanced medical services pharmacies deliver educational information at multiple points of contacts and also to raise awareness of the disease are of great importance.

These include over the counter (OTC) and the personal care aisle, a pharmacy counter, specialties publications and pickup areas prescription. These innovations are useful not only for customers' pharmacies but also create opportunities for pharmaceutical marketers, measurable return on investment.

The educative center of occupational programs and schemes growingly identifies the necessity for the possibility to use the knowledge obtained via simulation laboratories or experiential studying, which needs corresponding faculties and personnel conditions to satisfy these educational necessities.

ABSTRACT

Due to naturally varying geological conditions and insufficient data, it is difficult to analyse subsurface parameters for ease of excavation in geo-environmental surveys. The surveys mostly rely on traditional sample digging/drilling, which is costly and arduous, provides single point data, and may result in geologic model misinterpretation. Geophysical surveying techniques, like seismic refraction surveys, on the other hand, are non-destructive, rapid, and multidimensional. As a result, the current study attempted to determine seismic velocities (P-waves) using a seismic refraction survey to generate two-dimensional tomographic cross-sections for the purpose of characterizing various subterranean zones and layers of Jawi site in Perai, Malaysia. Correlation with drilled data from boreholes was performed to estimate the ease of excavation as zones of rippable, non-rippable, and boundary (marginal) and to interpret the geologic units based on seismic velocity and N values as soft to hard geologic conditions iapproximately 2.2 km/s and 2-50, respectively. The study consisted of low, moderate, and high material strengths, according to both outcomes. Through 2D seismic models, the findings also show multidimensional subsurface diversity. This will eliminate uncertainties brought on by insufficient borehole tests, provide a substantial amount of earth materials in space, and improve the precision of geological models used in building designs and plans.

Keywords: Seismic Refraction, Traditional Method, Material Strength.

1. INTRODUCTION

Estimating the cost and the method of excavation is critical in rippability assessments. Excavation means the act of removing rock fragments from the parent/ main rock and is traditionally carried out using approaches involving rock units being dug, ripped, or blasted (Mohamad et al., 2019; Sparmanto et al., 2023). Amongst the common methods normally employed for excavation, ripping is simply the breakdown of unconsolidated rock masses to detach disjointed material, and has more merits in terms of cost-effectiveness, minimal earth disturbance and degradation, as compared to blasting, breaking the rocks into different sizes with strong force and great earth shaking. Though ripping is considered safe and friendly but has inherent difficulties for decision-making on ripping a rock and its associated cost.

Geophysical method of seismic refraction measures wave velocities of different rock types as it propagates through the complex earth subsurface. The velocity values are embodied on ripper performance chart suggesting the status of rock, rippable, marginal, or non-rippable (Caterpillar

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Tractor Company, 2001). Seismic method is currently employed in rippability investigations due to its non-invasive nature and low cost, by several scholars such as (Aziman et al., 2019; Akingboye & Bery et al., 2022; Sparmanto et al., 2023). Despite the strength of seismic refraction in providing good information with respect to Caterpillar chart, additional information for instance discontinuity spacing and strength affect the excavation (Mohamad et al., 2011). However, current studies by (Muztaza et al., 2022) indicated the usability of seismic approach to evaluate site excavations prior to site development for a quarry. The study revealed that two-dimensional near surface model and the estimated rippability volume of the site were achieved in a cheap and less time-consuming manner. In the same vein, inhomogeneity in rock layering from uneven composition and spread of rock and mineral masses in different parts in granitic quarry area, have been determined through the seismic velocity models (Kausarian et al., 2014).

In different geologic environments and due to complex nature of the subsurface, seismic method aids in providing subsurface information such as weathering, density, porosity, strength, and overall rock mass characteristics, etc., to engineers, geologists and architects and is appropriate to be implemented at project site prior to the construction works. Comparison of geophysical and traditional methods was made by (Olona et. al, 2010), revealing the strength of geophysics through robust characterisation of non-homogeneous rock units. Hazreek et al., 2013, obtained a 2D model generating various information related to stratigraphy and subsurface geologic units. Presently, seismic refraction has proved to be applicable in a wide range of fields, especially for engineering works.

The present study takes into cognizance the strength of seismic refraction method for 2D subsurface model and overburden thicknesses and depth of geologic materials and integrated with traditional method. Though traditional methods, such as geological mapping and geotechnical techniques, for assessing earth's crust, provide real results for rock mass and associated properties, but non-invasive seismic refraction technique is used in multi-dimensional characterisation of complex geologic materials of rocks and soils. It is therefore crucial, to implement seismic refraction technique integrated with traditional methods, to improve field exploration thereby mitigating its challenges of hidden features and one-dimensional information, and cost.

2. MATERIALS and METHODS

The study area is located at Jawi, Seberang Perai Selatan which consist of marine clay, silt and few thin layers of sand (Ariffin et al., 2019) as depicted in Figure 1(a). The seismic refraction consists of the source, which is a sledgehammer of approximately 7000 g, a receiver in form of geophones, and a seismograph. The Mk-8 seismograph was used in the survey as a recording entity, with 24 detectors connected to it and the source was used for striking of a metallic plate for generating signals (Sparmanto et al., 2023). In the present study as depicted in figure 1(a), a seismic refraction survey profile was carried out, (Line1) with total length of each profile 115 m It was presumed that important seismic velocity disparities among granitic rock and overburden (on top of rock) may perhaps be detected. Figure 1(b) depicts the geological setting of the study area with flat topographic changes.

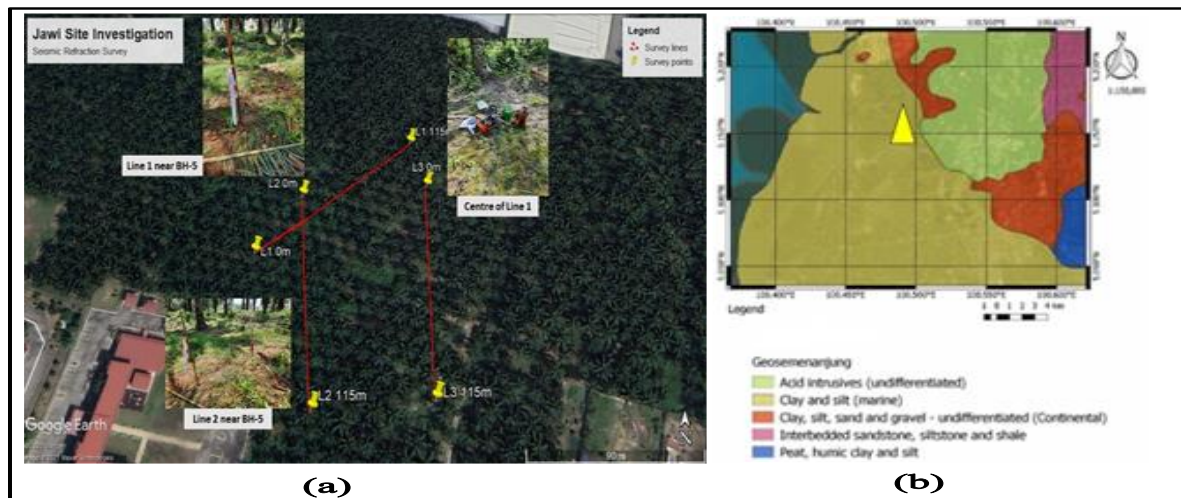

Figure 1(a) A Google map showing the study site and profile layout; (b) Geological map of the study.

3. FINDINGS and DISCUSSION

The 2D seismic refraction and excavability models for the surveyed line were interpreted and correlated with borehole records (Figure 2). The seismic velocity values for the first material range from 0.2 to 1.6 km/s. This material is clay soil with N values ranging from 2 to 7 (from soft to medium stiff condition). The following material has seismic velocity values in the 1.6 – 1.8 km/s range. This area is classified as silty SAND soil with a N value of 8. The third material has seismic refraction values ranging from 1.8 – 2.2 km/s. This material is classified as silty CLAY with an N value range of 11 – 34 respectively. The final material has values ranging from 2.2 – 3.2 km/s. This material is classified as clayey SILT with N values ranging from 38 – 50 (hard condition). Based on their strength properties, the gradual variation and transition in seismic velocity values could be traced back to different subsurface lithological units (Hassan et al., 2021b)

Furthermore, the 2D rippability model obtained and interpreted from the seismic refraction velocities with underground geo-material features, indicating two regions of rippable and moderate rippability (marginal) separated by a border region at velocity of 2.2 km/s where the soil consistency changes from very stiff to hard. The thickness of the rippable layer was estimated to be between 17 and 20 m (from surface).

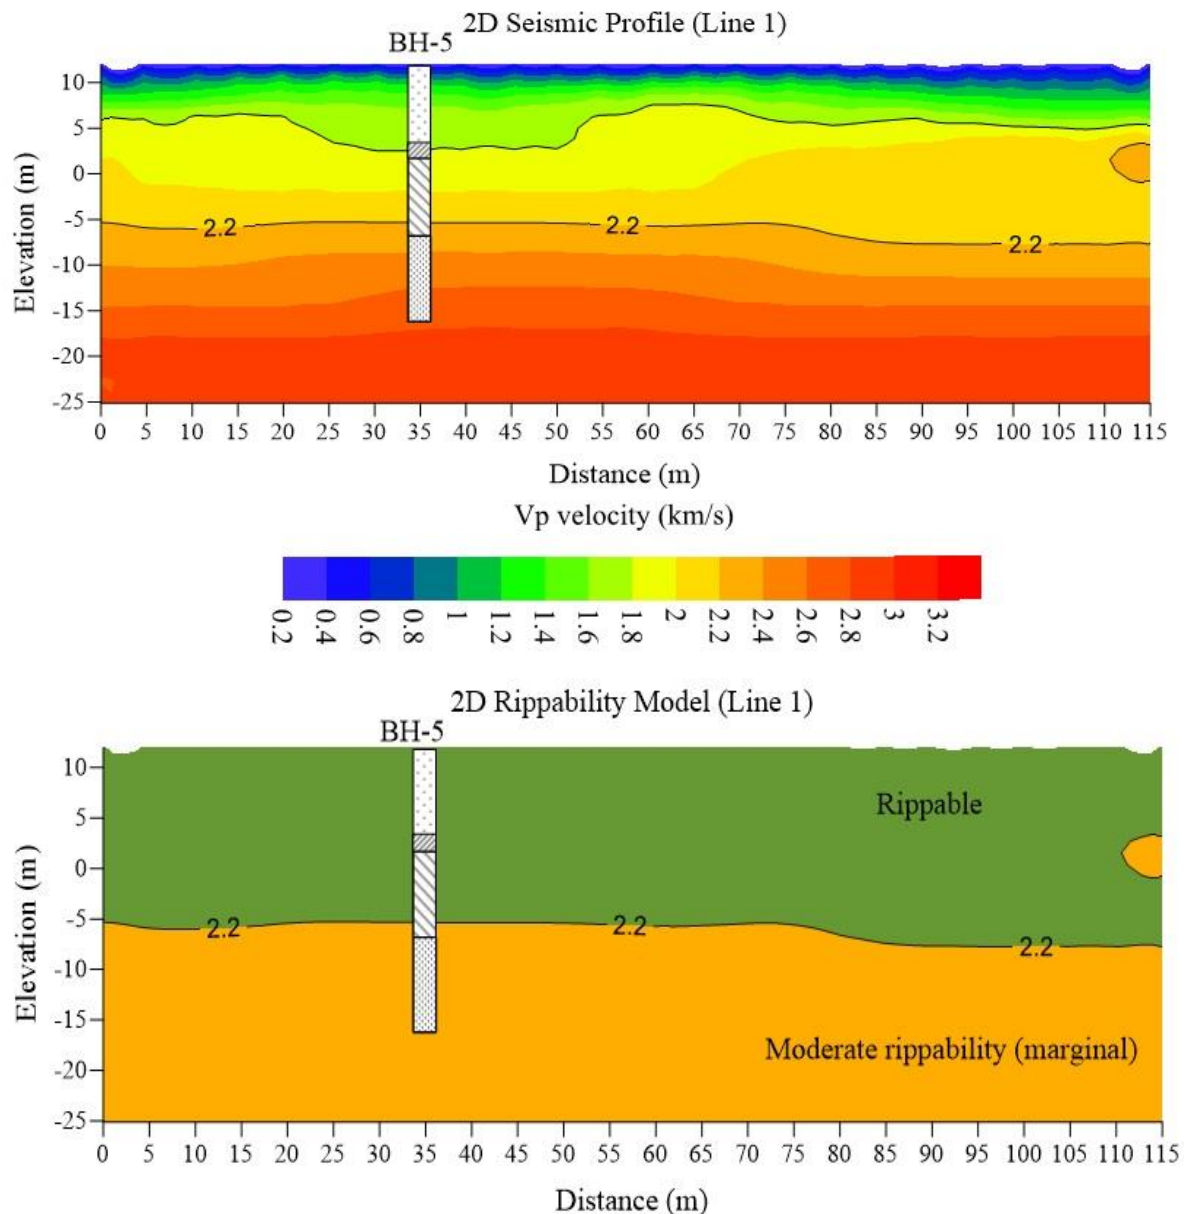

Figure 2: 2D seismic and rippability models for Line 1.

The seismic survey line reveals a vital hidden transition boundary belonging to marginal portion with thickness of about 18 m from the ground surface, which signifies the interface of the rippable and moderate rippability geomaterials, occurring at seismic velocity values of 2.2 km/s. The 2.2 -3.2 km/s moderate rippability region moves downward approaching the bedrock in the study area.

4. CONCLUSION and RECOMMENDATIONS

The methods used in this study have successfully revealed the covered variability of the subsurface as regions of rippable and non-rippable based on the velocity values and borehole data. The seismic results determine the 2D tomographic models, revealing multi-spatial variation of the subsurface. The study examines the natural heterogeneity and strength of the geomaterials from soft to hard rock units of the studied area, based on the seismic velocity

values and rippability models as critical phase for construction designs of infrastructural development.

Thanks and Information Note

We thank the organizers and the reviewers for their great efforts and contributions for the success of the conference.

ABSTRACT

Aim of the research was to study and analyze the key issue aspects related of action and outlook of use monoclonal antibodies in miscellaneous immunotherapeutic directions. Monoclonal antibodies are increasingly becoming a standard part of clinical cancer treatment. Monoclonal antibodies are approved by the Food and Drug Administration for the treatment of cancer in the United States. Oncology nurses are expected to be familiar with these agents, their indications, and their adverse effects, to provide appropriate care and symptom management to patients receiving these agents, and to adequately educate patients and families about these treatments and their specific and overlapping side effects. Most monoclonal antibodies by themselves have little antitumor activity, even after binding to the target antigen. Some notable exceptions include monoclonal antibodies to HER2, EGFR, and CD20, which have remarkable activity against tumors expressing these antigens. However, despite scant antitumor activity of monoclonal antibodies, their specificity for the target antigen makes them useful cancer therapeutic agents. Antitumor activity has been accomplished by conjugating antibodies with different effector molecules that accomplish cell death after antibody binding and

internalization. Such effector molecules include cytotoxic agents, bacterial or plant protein toxins (immunotoxins), and radiopharmaceutical agents. Monoclonal antibodies targeting specific inflammatory cytokines are undoubtedly revolutionary drugs in many fields of medicine and have begun a new chapter in the treatment of severe and complex cases of immunological diseases. This is also the case in severe asthma, where have moved from demanding and aggravating oral steroid therapy to a targeted and personalized immunological approach. In asthma, the use of monoclonal antibodies has given many patients the chance to control their disease and significantly improve their quality of life. However, there is still a need to develop new therapies that will be effective in more complex and unusual cases, or where existing treatment has not been successful.

Keywords: Aspects, Action, Use, Monoclonal Antibodies, Miscellaneous, Immunotherapeutic, Disease.

1. INTRODUCTION

Monoclonal antibodies (mAbs) are an important therapeutic class with complex pharmacology and interdependent pharmacokinetic (PK) and pharmacodynamics (PD) properties. Understanding the PK and PD of mAbs and their biological and mechanistic underpinnings are crucial in enabling their design and selection, designing appropriate efficacy and toxicity studies, translating PK/PD parameters to humans, and optimizing dose and regimen to maximize success in the clinic. Significant progress has been made in this field however many critical questions still remain. This article gives a brief overview of the PK and PD of mAbs, factors that influence them, and areas of ongoing inquiry (Martin-Aguilar et al., 2022; Scheibe et al., 2022; Beadon et al., 2018; Nobile-Orazio et al., 2014).

Monoclonal antibody (mAb) therapeutics are an important and rapidly growing class of therapeutic agents with over 470 molecules in the clinical pipeline and many more in earlier stages of drug development. Selecting the right mAb is a key determinant of its clinical success and depends on early understanding of its PK/PD and successfully translating it to humans. Compared to small molecules, biologics such as mAbs have unique characteristics that make their pharmacokinetics (PK) and pharmacodynamics (PD) quite complex. An integrated understanding of its PK/PD characteristics including exposure at the site of action, target occupancy and expression of functional pharmacological activity are important in improving its clinical success. The utility of translational PK/PD spans different phases of drug development and can contribute to target evaluation, design and selection of candidate molecule with optimal properties, and dose and regimen selection in preclinical and clinical studies. Understanding PK/PD of mAbs and factors that impact them, are essential to achieve these translational goals. This review describes the PK and PD characteristics of mAbs, and translational PK/PD approaches to predict human PK/PD (Sudo, et al., 2016; Vlam et al., 2015; Thomas et al., 2016; Van Hoecke et al., 2019).

Monoclonal antibodies (mAb) are revolutionising the treatment of many different diseases. Given their differing mode of action compared to most conventional chemotherapeutics and small molecule inhibitors, they possess the potential to be independent of common modes of treatment resistance and can typically be combined readily with existing treatments without

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

dose-limiting toxicity. However, treatments with mAb rarely result in cure and so a full understanding of how these reagents work and can be optimised is key for their subsequent improvement. Here we review how an understanding of the biology of the inhibitory Fc receptor, FcγRIIB (CD32B), is leading to the development of improved mAb treatments Shepard et al., 2017; Edwards et al., 2021; Kelley et al., 2022; Li et al., 2013).

Aim of the research was to study and analyze the key issue aspects related of action and outlook of use monoclonal antibodies in miscellaneous immunotherapeutic directions.

2. METHODOLOGY

The material of the article was the revised data from scientific publications, which were processed, analyzed, overviewed and reviewed by generalization and systematization. Research studies are based on a review/overview assessment of the development of critical visibility and overlook of the modern scientific literature. Use the following databases: (for extensive literature searches to identify the key issue aspects related of action and outlook of use monoclonal antibodies in miscellaneous immunotherapeutic directions.) PubMed, Web of Science, Clinical key, Tomson Reuters, Google Scholar, Cochrane Library, and Elsevier Foundations.

3. RESULTS and DISCUSSION

Monoclonal antibodies are essential tools for many molecular immunology investigations. In particular, when used in combination with techniques such as epitope mapping and molecular modelling, monoclonal antibodies enable the antigenic profiling and visualization of macromolecular surfaces. In addition, monoclonal antibodies have become key components in a vast array of clinical laboratory diagnostic tests. Their wide application in detecting and identifying serum analytes, cell markers, and pathogenic agents has largely arisen through the exquisite specificity of these unique reagents. Furthermore, the continuous culture of hybridoma cells that produce these antibodies offers the potential of an unlimited supply of reagent. In essence, when compared with the rather limited supply of polyclonal antibody reagents, the feature of a continuous supply enables the standardization of both the reagent and the assay technique. Clearly, polyclonal and monoclonal antibodies have their advantages and disadvantages in terms of generation, cost, and overall applications. Ultimately, monoclonal antibodies are only produced when necessary because their production is time consuming and frustrating, although greatly rewarding (at least most of the time!). This is especially apparent when a monoclonal antibody can be applied successfully in a routine pathology laboratory or can aid in the clinical diagnosis and treatment of patients Litzow et al., 2013; Stock et al., 2008; Huguet et al., 2009).

Monoclonal antibody-based treatment of cancer has been established as one of the most successful therapeutic strategies for both hematologic malignancies and solid tumors. In addition to targeting cancer antigens antibodies can also modulate immunological pathways that are critical to immune surveillance. Antibody therapy directed against several negative immunologic regulators (checkpoints) is demonstrating significant success in the past few years. Immune checkpoint inhibitors, ipilimumab, pembrolizumab and nivolumab, have shown

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

significant clinical benefit in several malignancies and are already approved for advanced melanoma and squamous NSCLC. Based on their mechanism of action, these agents can exert toxicities that are unlike conventional cytotoxic chemotherapy, whose nature is close to autoimmune diseases - immune related adverse events (irAEs). In this review we focus on the spectrum of irAEs associated with immune checkpoint antibodies, discussing the pharmacological treatment strategy and possible clinical impact (Kantarjian et al., 2012; Dworzak et al., 2008; Thomas et al., 2010).

Monoclonal antibodies (mAbs) are a rapidly growing class of human therapeutics representing Cancer diseases are one of the major groups where monoclonal antibodies are used in clinical practice. There have been twelve antibodies that have received approval from the FDA for the treatment of a variety of solid tumors and hematological malignancies. In addition, there are a large number of additional therapeutic antibodies that are currently being tested in early- and late-stage clinical trials. The most common type of mAbs used to treat cancer are “naked mAbs”. Most naked mAbs attach to antigens on cancer cells, but some work by binding to antigens on other, non-cancerous cells, or even free-floating proteins. We can simplify three major mechanisms of actions of naked mAbs. One principle is boosting a person’s immune response against cancer cells by attaching to them and acting as a marker for the body’s immune system to destroy them. An example is alemtuzumab, which binds to the CD52 antigen on lymphocytes and is used to treat some patients with chronic lymphocytic leukemia (CLL). Another naked mAbs work mainly by attaching to and blocking antigens on cancer cells that help cancer cells grow or spread. For example, trastuzumab is an antibody against the HER2 protein (Hoelzer et al., 2010; Carnahan et al., 2010; Leonard et al., 2003).

Since then, monoclonal antibodies have entered almost every branch of biomedical research. Antibodies are now used as frontline therapeutics in highly divergent indications, ranging from autoimmune disease over allergic asthma to cancer. Wider accessibility and implementation of antibody-based therapeutics is however hindered by manufacturing challenges and high development costs inherent to protein-based drugs. For these reasons, alternative ways are being pursued to produce and deliver antibodies more cost-effectively without hampering safety. Over the past decade, messenger RNA (mRNA) based drugs have emerged as a highly appealing new class of biologics that can be used to encode any protein of interest directly in vivo. Whereas current clinical efforts to use mRNA as a drug are mainly situated at the level of prophylactic and therapeutic vaccination, three recent preclinical studies have addressed the feasibility of using mRNA to encode therapeutic antibodies directly in vivo. The highlight the potential of mRNA-based approaches to solve several of the issues associated with antibodies produced and delivered in protein format. We identify key hurdles that mRNA-based approaches still need to take to fulfill this potential and ultimately replace the current protein antibody format (Raetz et al., 2008; Raetz et al., 2011; Advani et al., 2012).

Autoimmune diseases of the peripheral nervous system have so far been treated mainly with exogenous high-dose intravenous immunoglobulins (IVIg), that act through several mechanisms, including neutralization of pathogenic autoantibodies, modulation of lymphocyte activity, interference with antigen presentation, and interaction with Fc receptors, cytokines, and the complement system. Other therapeutic strategies have recently been developed, in part

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

to address the increasing shortage of IVIg, prime among which is the use of B cell depleting monoclonal antibodies, or small molecule inhibitors targeting the B-cell specific kinases. Rituximab, a chimeric monoclonal antibody against CD20 + B lymphocytes, is currently the most used, especially in anti-MAG antibody neuropathy and autoimmune neuropathies with antibodies to nodal/paranodal antigens that are unresponsive to IVIg. After several reports of its efficacy in chronic inflammatory demyelinating polyradiculoneuropathy (CIDP), rituximab is currently under investigation in three Phase 2 trials in CIDP. In addition, the possible role of complement activation in the pathogenesis of chronic autoimmune neuropathies has brought into consideration drugs that can block the complement cascade, such as eculizumab, a monoclonal antibody already assessed in acute polyradiculoneuropathies, and approved for myasthenia gravis. Preliminary data on eculizumab in multifocal motor neuropathy have been published, but randomized controlled studies are pending. Moreover, the neonatal Fc receptor, that recycles IgGs by preventing their lysosome degradation, is an important and attractive pharmacological target. Antibodies against FcRn, which reduce circulating IgG (both pathogenic and non-pathogenic) have been developed. The FcRn blocker efgartigimod, a humanized IgG1-derived Fc fragment, which competitively inhibits the FcRn, has recently been approved for the treatment of myasthenia gravis and is currently under investigation in CIDP. In addition, the anti-human FcRn monoclonal antibody rozanolixizumab is currently being assessed in phase 2 trials in CIDP. However, none of the abovementioned monoclonal antibodies is currently approved for treatment of any immune-mediated neuropathies. While more specific and individualized therapies are being developed, the possibility of combined treatments targeting different pathogenic mechanisms deserves consideration as well (Advani et al., 2010; Thorson et al., 2000; Advani et al., 2010).

Monoclonal antibodies have recently gained interest in the treatment of immune-mediated neuropathies, particularly when there is evidence of underlying humoral pathogenetic mechanisms.

More data are available for the polyneuropathy with antibodies to myelin-associated glycoprotein (MAG), but increasing evidence is also emerging for other immune-mediated diseases of the peripheral nervous system, including chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) and autoimmune neuropathies with antibodies to nodal and paranodal antigens.

Moreover, a potential pathogenic role of complement in chronic autoimmune neuropathies may open new therapeutic avenues with drugs inhibiting complement activation. Eculizumab, a recombinant humanized monoclonal antibody that binds and sequesters C5a, prevents its enzymatic cleavage by the C5 convertase into C5a and C5b, thus inhibiting C5b-9 membrane attack complex (MAC) formation. Eculizumab has already been approved in myasthenia gravis and is under investigation in acute polyradiculoneuropathies. A further potential therapeutic target in immune-mediated polyneuropathies is the neonatal Fc receptor (FcRn), known to facilitate IgG recycling and protection from degradation, thereby extending the half-life of IgG molecules. High-dose intravenous immunoglobulins (IVIg), currently used in several immune-mediated diseases, act through several mechanisms, including competition with pathogenic autoantibodies for FcRn binding, saturating the receptor and thus increasing IgGs turnover.

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Monoclonal antibodies against FcRn may be effective in reducing serum levels of pathogenic IgG autoantibodies without removing other circulating factors. The FcRn blocker efgartigimod has recently been approved by the U.S. Food and Drug Administration for the treatment of anti-acetylcholine receptor antibody positive myasthenia gravis and is currently under investigation in CIDP (Kantarjian et al., 2012; O'Brien et al., 2012; Nagorsen et al., 2012).

However, even if they hold promise, none of the above-mentioned therapeutic monoclonal antibodies are currently approved for treatment of any of the immune-mediated neuropathies. We reported on the currently used monoclonal antibodies in the treatment of chronic immune-mediated neuropathies, and present preliminary data on new potential therapeutic strategies.

Antibody-drug conjugates are monoclonal antibodies conjugated to cytotoxic agents. They use antibodies that are specific to tumour cell-surface proteins and, thus, have tumour specificity and potency not achievable with traditional drugs. Design of effective antibody-drug conjugates for cancer therapy requires selection of an appropriate target, a monoclonal antibody against the target, potent cytotoxic effector molecules, and conjugation of the monoclonal antibody to cytotoxic agents. Substantial advances in all these aspects in the past decade have resulted in regulatory approval of ado-trastuzumab emtansine and brentuximab vedotin for clinical use. Several promising antibody-drug conjugates are now in late-phase clinical testing. Ongoing efforts are focused on identifying better targets, more effective cytotoxic payloads, and further improvements in antibody-drug linker technology. Improved understanding of the mechanistic basis of antibody-drug conjugate activity will enable design of rational combination therapies with other agents, including immunotherapy (Goebeler et al., 2011; Topp et al., 2012; Topp et al., 2012).

Most monoclonal antibodies by themselves have little antitumour activity, even after binding to the target antigen. Some notable exceptions include monoclonal antibodies to HER2, EGFR, and CD20, which have remarkable activity against tumours expressing these antigens. However, despite scant antitumour activity of monoclonal antibodies, their specificity for the target antigen makes them useful cancer therapeutic agents. Antitumour activity has been accomplished by conjugating antibodies with different effector molecules that accomplish cell death after antibody binding and internalisation. Such effector molecules include cytotoxic agents, bacterial or plant protein toxins (immunotoxins), and radiopharmaceutical agents (Kreitman et al., 2011; Wayne et al., 2010).

New biologic therapies come in several basic forms, either growth factors and cytokines (such as erythropoietin, G-CSF, interferon, enzymes, factors that regulate coagulation) or, more commonly, monoclonal antibodies (mAbs) and related proteins such as 'traps' in which cytokine receptors are made soluble and fused with antibody constant regions. The latter group (mAbs and traps) have dramatically advanced the therapy of chronic inflammatory diseases and cancer. We describes mAbs and relatives in different direction of therapeutics. The tumour necrosis factor (TNF)-blockers for autoimmune/inflammatory diseases are the most broadly deployed (with multiple products) and have engendered a revolution in therapeutic research/development, along with rather remarkable revenues. This therapeutic revolution is based on the synergy of three scientific disciplines: immunology, molecular biology and protein engineering (Wayne et al., 2011; Herrera et al., 2009; Park et al., 2010).

Monoclonal antibody (mAb) therapies for treatment of patients with COVID-19 have been launched at an unprecedented pace by multiple companies, delivering clinically meaningful

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

interventions since. Emergency-use authorization (EUA) has been granted by many countries in record-time allowing hundreds of thousands of patients to benefit. What was once an audacious goal and medical imperative to develop and deliver mAb therapies early in the pandemic has now come to pass (Park et al., 2010; Porter et al., 2011).

This is an amazing achievement for the pharmaceutical industry and regulatory health authorities and speaks to the maturation and broad acceptance of mAbs as therapeutics. Without question, delivering these mAbs in record time was only made possible by the industry convergence on mAb platform processes and each company's existing manufacturing networks. This review will share experiences from our COVID-19 journey at Vir Biotechnology and GlaxoSmithKline to develop sotrovimab and other antiSARS-CoV-2 mAbs and include perspectives from other companies that have been shared publicly in nearly two years since the COVID-19 pandemic began. We consider how will the experiences catalyze changes to the development of future mAb products. Informed by production history and approved of over 100 licensed mAbs. The implications chemistry, manufacturing, and control (CMC) development strategies for COVID-19 mAbs may have for development of future mAb products (Kochenderfer et al., 2012; Haso et al., 2012).

Patients with moderate-to-severe asthma may now be treated using a variety of monoclonal antibodies that target key inflammatory cytokines involved in disease pathogenesis. Existing clinical data on anti-IgE, anti-IL-5 and other immunological pathways indicate these therapies to offer reduced exacerbation rates, improved lung function, greater asthma control and better quality of life. However, as several patients still do not achieve satisfactory clinical response with the antibodies available, many more biologics, aiming different immunological pathways, are under evaluation. This review summarizes recent data on existing and potential monoclonal antibodies in asthma. Recent advances have resulted in the registration of a new antibody targeting (tezepelumab), with others being under development. Some of the researched monoclonal antibodies (e.g. anti-IL-13 tralokinumab and lebrikizumab or anti-IL-17A secukinumab) have shown optimistic results in preliminary research; however, these have been discontinued in asthma clinical research. In addition, as available monoclonal antibody treatments have shown little benefit among patients with T₂-low asthma, research continues in this area, with several antibodies in development. This article summarizes the available pre-clinical and clinical data on new and emerging drugs for treating severe asthma, discusses discontinued treatments and outlines future directions in this area (Han et al., 2013; Dank et al., 2013).

Lebrikizumab is humanized IgG4 monoclonal antibody targeting IL-13 that has been intensively studied in moderate-to-severe asthma. It has been evaluated in several phase II and phase III studies. In phase II studies it has demonstrated reduced exacerbation rates and improved FEV1 in patients with uncontrolled asthma, particularly among those with high periostin concentration or blood eosinophil count.

Brodalumab is a human, IgG2 monoclonal antibody targeting IL-17RA, which is currently registered for the treatment of psoriasis vulgaris, psoriatic arthritis, pustular psoriasis and psoriatic erythroderma. The drug was studied in a randomized, double-blind phase II study with 315 participants in four groups: placebo, brodalumab 140 mg, brodalumab 210 mg and brodalumab 280 mg. No clinically significant differences were observed between the groups in terms of ACQ score, FEV1, morning PEF, SABA use, daily and nighttime symptom scores or symptom-free days. A predefined subgroup analysis found that only the high bronchodilator

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

reversibility subgroup demonstrated clinically significant benefits (Stopforth et al., 2016; Bruhns et al., 2009).

Anakinra is a human IL-1 receptor antagonist produced by recombinant DNA technology in an *E. coli* expression system. As the IL-1-regulated pathway is believed to play a significant role in asthma pathogenesis in both Th2/Th17-high and -low phenotypes, it has become an attractive therapeutic target. However, two recent clinical trials that were designed to assess the effectiveness of anakinra as a rescue treatment for airway inflammation in allergic asthma, either through early- or late-phase administration after allergen challenge (Lim et al., 2011; Budde et al., 2014).

Monoclonal antibodies targeting specific inflammatory cytokines are undoubtedly revolutionary drugs in many fields of medicine and have begun a new chapter in the treatment of severe and complex cases of immunological diseases. This is also the case in severe asthma, where have moved from demanding and aggravating oral steroid therapy to a targeted and personalized immunological approach. In asthma, the use of monoclonal antibodies has given many patients the chance to control their disease and significantly improve their quality of life. However, there is still a need to develop new therapies that will be effective in more complex and unusual cases, or where existing treatment has not been successful (Brooks et al., 2019; Goede et al., 2014).

Monoclonal antibodies (mAbs) have shown impressive therapeutic benefit for a range of diseases including cancer, autoimmune disease and infectious disease. As such, they are the fastest growing sector in the biopharmaceutical market, with over \$100B in sales each year and a projection to double that within the next several years.¹ Today, the market for mAbs is overwhelming high-income countries. The majority of the more than 500 mAbs now in clinical testing⁵ are for oncology and autoimmune indications. However, with the recent clinical success and regulatory approvals of mAbs for Ebola virus disease and COVID-19, neglected infectious diseases are anticipated to represent a significant percentage of the future therapeutic antibody market. Currently, there are over 75 clinical trials of mAbs against ~20 infectious pathogens and mAbs for ~70 pathogens in preclinical development.² These include mAbs against SARS-CoV-2, HIV, influenza, respiratory syncytial virus (RSV), filoviruses, viral enteric pathogens and gram negative bacterial enteric pathogens, including *E.coli*, *Klebsiella*, *Shigella* and *Salmonella* (White et al., 2011; Li et al., 2011; Clynes et al., 2000).

The monoclonal antibody (mAb) against CD20 known as Rituxan is widely used to treat autoimmune diseases and lymphomas. However, further application of Rituxan faces challenges of high production cost, which limits its availability in developing countries. The report a new approach for large production of a recombinant anti-CD20 mAb in the milk of transgenic cattle (at a yield of up to ~6.8 mg/mL), with recovery rate and purity. Crystallography study showed that our recombinant mAb is structurally nearly identical to Rituxan with only minor differences in N-linked glycosylation pattern. Functional study showed that, while our mAb shared similar target-cell binding capacities and complement-dependent cytotoxicity with Rituxan, our product exhibited a higher binding affinity for FcγRIIIα and a greater antibody-dependent cellular cytotoxicity. Accordingly, our recombinant mAb demonstrated a superior efficacy over Rituxan against B-cell lymphomas in severe combined immunodeficiency mice. Taken together, our data supports transgenic cattle as a novel model for cost-competitive, large-scale production of therapeutic antibodies (Nimmerjahn et al., 2005; DiLillo et al., 2015).

Monoclonal antibodies (mAbs) comprise an essential type of biologic therapeutics and are used to treat diseases because of their anti-cancer and anti-inflammatory properties, and their ability to protect against respiratory infections. Its production involves post-translational glycosylation, a biosynthetic process that conjugates glycans to proteins, which plays crucial roles in mAb bioactivities including effector functions and pharmacokinetics. These glycans are heterogeneous and have diverse chemical structures whose composition is sensitive to manufacturing conditions, rendering the understanding of how specific glycan structures affect mAb bioactivity challenging. There is a need to delineate the effects of specific glycans on mAb bioactivity to determine whether changes in certain glycosylation profiles (that can occur during manufacturing) will significantly affect product quality. Using enzymatic transglycosylation with chemically-defined N-glycans, we show that galactosylation at a specific location of N-glycans in an afucosylated anti-viral mAb is responsible for FcγRIIIA binding and antibody-dependent cell-mediated cytotoxicity (ADCC) activity. We reported a facile method to obtain purified asymmetric mono-galactosylated biantennary complex N-glycans, and their influence on bioactivity upon incorporation into an afucosylated mAb. Using ELISA, surface plasmon resonance and flow cytometry, we show that galactosylation of the $\alpha 6$ antenna, but not the $\alpha 3$ antenna, consistently increases FcγRIIIA binding affinity. To confirm its relevance in an anti-viral model of respiratory syncytial virus (RSV) using an adapted ADCC reporter assay. Further correlate the structure-function relationship to the interaction of the galactose residue of the $\alpha 6$ antenna with the protein backbone using 2D- ^1H - ^{15}N -NMR, which showed that galactosylation at this location exhibited chemical shift perturbations compared to glycoforms lacking this galactose residue. Our results highlight the importance of identifying and quantifying specific glycan isomers to ensure adequate quality control in batch-to-batch and biosimilar comparisons (Schwab et al., 2015; Hargreaves et al., 2015).

The targeting of a single pro-inflammatory cytokine, TNF, to treat a complex disease in rheumatoid arthritis (RA) where multiple pro-inflammatory cytokines were upregulated was based on work using human disease tissue. They analyzed cytokine production from joints and cytokine regulation in cultures of rheumatoid synovium in which the majority of the cells survived, producing the mediators generated *in vivo*. In these cultures, blocking TNF- α reduced the production of many other inflammatory cytokines (IL-1, IL-6, GM-CSF, IL-8 etc), thus defining a 'TNF-dependent cytokine cascade'. The dramatic clinical success of TNF blockade, demonstrated first in late-stage RA then in earlier stage disease, also validated this concept. Noteworthy was the fact that tissue (bone and cartilage) damage was controlled. But also striking was the heterogeneity of the clinical response, with some individuals close to a cure and others virtually unimproved. The reasons for this are not yet clear, despite much work to try to elucidate the reasons. Genetic differences were an obvious possibility although never established, and recent clinical data demonstrating that non-responders may respond subsequently to anti-TNF has excluded it. Although anti-TNF in humans is relatively safe, more infections in patients occur, eg with intracellular organisms, especially tuberculosis. Many large patient registers have documented the long-term benefits of anti-TNF therapy, reduced some complications and maintained a favourable benefit/risk ratio (Nelson et al., 2000; Burioni et al., 2013; Levene et al., 2005).

Currently, anti-TNF is used in RA, Crohn's disease, ulcerative colitis, psoriasis, psoriatic arthritis, ankylosing spondylitis and juvenile RA; its use is now being explored in other indications. Anti-TNF antibodies are the most successful and widely used antibody-based

September 14-15, 2023, Naples, Italy

therapeutic. It is noteworthy that if used together with methotrexate early in the course of RA, over 50% of patients can be taken off infliximab and remain virtually disease-free, even with reduced dosage of methotrexate, and some patients can be taken off all medication.

At present, therapeutic monoclonal antibodies are being used in haematological and solid malignancies including non-Hodgkin's lymphoma, breast cancer and colorectal cancer. The mechanism of their antitumour effect is not precisely known but is thought to include complement-dependent cytotoxicity, antibody-dependent cellular cytotoxicity and blocking or steric hindrance of the function of the target antigen. This review focuses on current use in oncology but lists some of the antibodies in clinical development (Byrd et al., 2001; Brien et al., 2001).

Rituximab, a chimeric mAb to CD20, (an antigen in most B-cells although not plasma cells), was first to treat B-cell-driven cancers such as non-Hodgkin lymphoma. It was pioneered by Jo Edwards for RA and subsequently approved, but was not successful in systemic lupus erythematosus (SLE) trials. Anti-CD52 (alemtuzumab) is a first-generation humanised antibody, now used in multiple sclerosis. There are other antibodies approved, eg belimumab (also known as Benlysta) is an anti-BLys mAb approved for SLE, ustekinumab (also known as Stelara) is an antibody to the shared p40 subunit of IL-12 and IL-23 approved for psoriasis and psoriatic arthritis and potentially for Crohn's disease, and secukinumab (Cosentyx) is an anti-IL17A mAb approved for severe psoriasis and ankylosing spondylitis (Hainsworth et al., 2003; Kamath et al., 2016).

Modern mAb therapy of solid tumours was initiated by the humanised human epidermal growth factor receptor 2 (HER2) mAb trastuzumab. The science that laid the foundation for this breakthrough mAb also initiated personalised/biomarker driven drug discovery and treatment in oncology (Epenetos et al., 2009; Hiatt et al., 2014).

Trastuzumab, the first successful monoclonal anti-cancer antibody to be successful against solid tumours, is well tolerated in patients. The pathway leading to TNF-resistance of most tumour cell lines was unraveled by collaboration between the Shepard (Genentech) and Schreiber laboratories (Chicago), which revealed that macrophages kill tumor cells largely by secreting TNF. They hypothesised that if tumour resistance to macrophages could be reversed, the tumors would become sensitive to killing by host defense. Macrophage (or TNF)-resistant tumour cells implanted into syngeneic mice formed aggressive tumors, while their TNF-sensitive parental cells regressed (Demlova et al., 2016; Drewe et al., 2002).

Biologic therapies targeting B-cells are emerging as an effective strategy to treat a variety of immune-mediated diseases. One of the most studied B-cell-targeted therapies is rituximab, an anti-CD20 monoclonal antibody that exemplifies B-cell depletion therapy and has served as the prototype for other anti-CD20 monoclonal antibodies and the development of biosimilars. While there are multiple studies on the use of rituximab in dermatology, a comprehensive review of rituximab therapy in autoimmune skin conditions is lacking. In this literature review, we summarize indications, treatment efficacy, and safety of rituximab among common autoimmune diseases of the skin: pemphigus vulgaris, cutaneous lupus erythematosus, dermatomyositis, systemic sclerosis, thyroid dermopathy, autoimmune pemphigoid diseases, and cutaneous vasculitis diseases. Existing data on rituximab support the approach of rituximab, biosimilars, and newer B-cell-targeting therapies in immune-mediated cutaneous diseases. Overall, rituximab, which targets CD20, provides an effective alternative or concomitant option

to traditional immunosuppressants in the management of various autoimmune diseases of the skin. Further studies are necessary to expand the understanding and possible utility of B-cell-targeted therapies among autoimmune skin diseases (Smith et al., 2023; Lycke et al., 2022).

Biologic therapies targeting B-cells are emerging as an effective strategy to treat a variety of immune-mediated diseases. Overall, rituximab, which targets CD20, provides an effective alternative or concomitant option to traditional immunosuppressants in the management of various autoimmune diseases of the skin. Further studies are necessary to expand the understanding and possible utility of B-cell-targeted therapies among autoimmune skin diseases (Benavente et al., 2009; Ahmad et al., 2019).

Monoclonal antibodies have become the main type of antibody drug because of their high specificity and strong affinity to antigen. However, with the intensive study of the natural monoclonal antibody, many defects have faced, such as the limit times of binding to antigen, the unanticipated antibody clearance and antigen accumulation. Therefore, studies are no longer limited to the natural antibody screening, but rather to improve the efficiency of antibody drugs by engineering. In recent years, the bottlenecks in the development of conventional antibody have been solved effectively since the discovery of a novel recycling antibody. Recycling antibody binds to an antigen in plasma and dissociates from the antigen in endosome, thus maximizing the use of antibody and reducing antigen-mediated antibody clearance and antibody-mediated antigen accumulation. In addition, recycling antibodies can enhance the affinity with Fc receptors through further Fc modification (Mishima et al., 2011; Sickmier et al., 2016).

The mechanism of TNF-resistance of tumours needed to be widespread since most tumour cell lines were resistant. Sporn and Todaro's autocrine growth factor hypothesis of malignant transformation involving autocrine stimulation by transforming growth factors seemed plausible. Various growth factors were combined with TNF on TNF-sensitive tumour cell lines and growth factors that activated receptor tyrosine kinases converted TNF-sensitive tumour cells to TNF-resistant cells. Host defence was completely subverted and the growth inhibitor (TNF) even became a growth factor (Patel et al., 2007 Czuczman et al., 2008).

Much progress has been made during the last few decades in the treatment of malignancies. Many types of cancer cells comprising the tumor mass carry molecular markers that are not expressed or are expressed at much lower levels in normal cells. These findings provide new leads to drug design and development of therapeutic strategies involving monoclonal antibodies (mAbs) or related antibody drugs to treat malignancies. This article reviews recent advances in this targeting approach with a focus on the evolution and current use of prospective antibody drugs as effective ways to treat cancer (Nijhof et al., 2016; Seo et al., 2014).

Monoclonal antibody-based therapies bring the promise of increased response rates without excessive toxicity. The addition of rituximab to combination chemotherapy has shown encouraging results. Newer monoclonal antibody-based therapies linked to cytotoxic agents show promise. These include inotuzumab ozogamicin, an anti-CD22 antibody linked to calicheamicin that has produced significant single-agent responses in relapsed and refractory. Other monoclonal antibodies linked to plant or bacterial toxins are in earlier stages of development. Blinatumomab is a novel bispecific T-cell engaging antibody that combines single chain antibodies to CD19 and CD3 and brings a T cell in close proximity to a leukemic lymphoblast with resulting redirected lysis. This agent has demonstrated encouraging results in both the minimal residual disease setting and the relapsed/refractory setting. Autologous chimeric antigen receptor cells have shown promising responses in indolent B-cell lymphoid malignancies and are being tested in ALL. Many of these agents have the potential to increase response rates in older adults. Trials of many of these monoclonal antibody-based therapies are in various stages of development in the treatment of newly diagnosed (Lee et al., 2009; Braig et al., 2017).

The term monoclonal antibody refers to a single specificity antibody derived from a single B cell clone and initially these were created by fusing B cells (from immunised mice) with lymphoma cells. In clinical practice, however, the administration of murine antibodies induces human antimouse antibodies that may lead to allergic reactions and reduced efficacy. These difficulties have been partially overcome by recombinant technology to develop less immunogenic monoclonal antibodies. Chimaeric antibodies contain only a murine variable fragment whereas humanised antibodies only have a murine complementarity determining region (Nakadate et al., 2014; Valabrega et al., 2007).

Immunotoxins are recombinant proteins consisting of an antibody or antibody fragment targeting the tumour antigen, linked to protein toxins such as diphtheria toxin or pseudomonas exotoxin A.1 Up to now, the only immunotoxin approved by the US Food and Drug Administration (FDA) is denileukin difitox for treatment of CD25-positive cutaneous. Another immunotoxin, moxetumomab pasudotox, targeting CD22 has shown substantial activity in patients with hairy cell leukaemia and is now being assessed in a multicentre trial in patients with relapsed or refractory hairy cell leukaemia. In the case of solid tumours, immunotoxins have been less effective mainly because they induce an immune response restricting their activity. However, major tumour regressions were reported with an anti-mesothelin immunotoxin, in patients with treatmentrefractory mesothelioma when it was given in combination with pentostatin and cyclophosphamide (Gennari et al, 2004; Kasper et al., 2017).

Antibody–drug conjugates make use of antibodies that are specific to tumour cell-surface proteins⁶ and have tumor specificity and potency not achievable with traditional drugs. Although the idea of linking drugs to tumor-targeted antibodies was clear, development of therapeutic antibody–drug conjugates needed several technological advancements. Early antibody–drug conjugates were mouse monoclonal antibodies covalently linked to anticancer drugs such as doxorubicin, vinblastine, and methotrexate. These conjugates had little success in clinical trials because of immunogenicity, scant potency, suboptimum target selection, and insufficient selectivity for tumour versus normal tissue. The lessons from these early efforts led to improvements in technology and renewed interest in antibody–drug conjugates. Replacing murine antibodies with humanised or fully human antibodies prevented immunogenicity. Potency was improved by using drugs that were 100–1000 times more potent. Careful target

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

and antibody selection improved selectivity and efficiency of internalization (Cuyàs et al., 2017; Ozawa et al., 2017).

Ado-trastuzumab emtansine is an antibody–drug conjugate composed of trastuzumab and DM1, a maytansine derivative that is conjugated covalently to the antibody via a stable thioether linker. On binding to HER2, ado-trastuzumab emtansine undergoes receptor-mediated internalisation and subsequent proteolytic digestion, releasing the cytotoxic antimicrotubule agent within the target cells. Furthermore, it blocks HER2-mediated signal transduction, facilitates antibody-dependent cell-mediated cytotoxicity, and inhibits shedding of the HER2 extracellular domain.⁴³ Ado-trastuzumab emtansine was approved as a single agent for the treatment of patients with HER2-positive metastatic breast cancer who had previously received trastuzumab and a taxane, separately or in combination. The recommended dose of ado-trastuzumab emtansine is 3.6 mg/kg, administered as an intravenous infusion every 3 weeks (Xue et al., 2016; Kong et al., 2019).

Infliximab may be maintained during and eight weeks after repeated doses. These clinical improvements were accompanied by considerable healing of endoscopic lesions, although healing with stricture formation remains a concern. Histological disease activity was also dramatically reduced, with a decrease in inflammatory cell infiltrate and downregulation of activation markers and adhesion molecules occurring after treatment.

Etanercept is another anti-TNF agent licensed and effective for the treatment of refractory RA. Etanercept is a recombinant IgG1 Fc fragment fused to two p75 TNF receptors, as opposed to a monoclonal antibody. Etanercept has also been used as monotherapy in early RA, where it has comparable efficacy to methotrexate alone.¹⁵ It is given as a twice weekly subcutaneous injection.

Both Etanercept and Infliximab appear to reduce radiographical joint disease progression. The role of these biological agents in the treatment hierarchy still needs to be established, and currently they are likely to be used only for patients who have active disease despite previous use of at least two conventional disease modifying drugs. Etanercept has also been studied in psoriatic arthritis, where improvements in both joint pain and swelling and skin lesions have been demonstrated (Chandarlapaty et al., 2012; Jazirehi et al., 2007; Schmitz et al., 2015).

2007 Most patients with low grade or follicular lymphoma relapse with current treatments. Rituximab is a mouse human chimaeric IgG1 antibody that recognises the transmembrane phosphoprotein CD20 expressed by B cells and their related lymphomas. An infusion of Rituximab dramatically reduces circulating B cell numbers, through antibody dependent cellular cytotoxicity or apoptosis. Normal CD20 positive B cells are regenerated from early pre-B or stem cells (CD20 negative) in contradistinction to tumour cells, which have no equivalent counterpart.

The clinical benefits of monoclonal antibodies have been demonstrated, in particular, in patients with more severe disease, and often as an adjunct to standard treatments. In many instances, the regimens for these licensed monoclonal antibodies still need to be refined. The costs of monoclonal antibody treatment remain high but must be weighed against the potential gains in reducing disability, hospitalisation, and mortality.

While mAb has success as a monotherapy in some patients, treatment paradigms are trending towards employing them as combinations with chemotherapy, radiation, molecularly targeted

University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

drugs such as tyrosine kinase inhibitors, other antibodies against the same target, immune checkpoint inhibitors, vaccines, and/or cellular therapies. These many combination strategies are currently undergoing both preclinical investigation and clinical trials and this vast field is more exhaustively covered elsewhere. The cover combination therapies involving multiple monoclonal antibodies. It is now widely recognized that the mechanism of action of monoclonal antibodies includes an immune effector cell component. In particular, cetuximab efficacy has been partly attributed to ADCC, which can link innate and adaptive anti-tumor immune responses. Destruction of tumor cells via NK cell-mediated ADCC releases tumor cell specific proteins that when presented by antigen presenting cells to cytotoxic T cells leads to a more effective anti-tumor response. Head and neck squamous cell carcinoma (HNSCC) patients with durable responses to cetuximab have sustained anti-tumor specific immune responses. With the rise of immune checkpoint inhibitors that can further potentiate such immune responses, it is hypothesized that ICB may act in a synergistic manner with cetuximab. There is growing support combining anti-PD-1/PD-L1 mAbs with cetuximab in HNSCC patients. Additionally, combinations of either pembrolizumab or avelumab with cetuximab are currently in clinical trials. Likewise, the use of ICB in breast cancer in order to enhance anti-HER2 mAb therapies is a promising strategy. In fact, preclinical evidence suggests that resistance to trastuzumab monotherapy can be overcome by combination with ICB. Based on those results several clinical trials were formed to investigate the relationship between ICB and HER2-targeted mAbs. Preliminary results from the phase I/II PANACEA trial, which tested pembrolizumab combined with trastuzumab in treating breast cancer patients who overexpressed HER2, indicated synergy in the PD-L1+ patient subset.

Although there are many immune checkpoints of T-cell activation, each checkpoint has distinct mechanisms. Consequently, ICB combinations that target multiple checkpoints will enhance T cell responses in a synergistic manner. The combination of mAbs targeting CTLA-4 and PD-1 performed significantly better in preclinical mouse models than either antibody alone. Similarly, in metastatic melanoma patients combined therapy of ipilimumab and nivolumab was found to be more effective than either treatment used as a monotherapy. The FDA has since approved the combination of ipilimumab and nivolumab for melanoma. As the first ICB combination with FDA approval, ongoing clinical trials continue to evaluate ipilimumab plus nivolumab in other cancer types.

Anti-PD-1 mAbs are most often used in combinatorial strategies due to their more favorable toxicity profile in contrast to anti-CTLA-4 monoclonal antibodies. The immune checkpoints LAG3 and TIM3 are commonly found co-expressed with PD-1 on exhausted T cells. ICB of LAG3 combined with anti-PD-1 is undergoing clinical trial in glioblastoma and other cancers. There are similar clinical trials for the combination of anti-TIM3 and anti-PD-1 antibodies in liver cancer and several other solid tumors. Another promising combination strategy involves uniting ICB with agonistic antibodies that activate stimulatory receptors. 4-1BB is a costimulatory receptor found on T cells and NK cells and clinical trials that evaluate 4-1BB agonist antibodies in combination with anti-PD-1 mAb therapy are underway. An agonist antibody to the glucocorticoid-induced tumor necrosis factor receptor-related protein (GITR), which promotes T cell activation, also proved to be successful when combined with nivolumab.

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Additional mAb combinations that include agonist antibodies to OX40, which only becomes expressed on activated T cells, are the subject of multiple clinical trials.

Antibody therapy is effective for treating infectious diseases. Due to the coronavirus disease 2019 (COVID-19) pandemic and the rise of drug-resistant bacteria, rapid development of neutralizing monoclonal antibodies (mAbs) to treat infectious diseases is urgently needed. Using a therapeutic human mAb with the lowest immunogenicity is recommended, because chimera and humanized mAbs are occasionally immunogenic. In order to directly obtain naïve human mAbs, there are three methods: phage display, B cell receptor (BCR) cDNA sequencing of a single cell, and antibody-encoding gene and amino acid sequencing of immortalized cells using memory B cells, which are isolated from human peripheral blood mononuclear cells of healthy, vaccinated, infected, or recovered individuals. After screening against the antigen and performing neutralization assays, a human neutralizing mAb is constructed from the antibody-encoding DNA sequences of these memory B cells. This review describes examples of obtaining human neutralizing mAbs against various infectious diseases using these methods. However, a few of these mAbs have been approved for therapy. Therefore, antigen characterization and evaluation of neutralization activity *in vitro* and *in vivo* are indispensable for the development of therapeutic mAbs. These results will accelerate the development of antibody drug as therapeutic agents.

Two points in the strategy to develop therapeutic human neutralizing mAbs need to be considered. One is to thoroughly characterize the antigen. It is necessary to clarify which domain yields the mAb with the highest neutralization activity because mAbs acquired via highly antigenic antigens do not always have high neutralization activity. Moreover, obtaining mAbs against various epitopes is also important to enhance neutralization activity. In some cases, neutralization activity can be dramatically improved by making a cocktail containing multiple mAbs with different targets. When developing a cross-reactive neutralizing mAb, it is suitable to use an antigen containing a sequence that is conserved across different species not only in the primary structure but also in the tertiary structure. Another point is to evaluate the neutralization activity *in vitro* and *in vivo*. AED must always be considered when developing human mAb therapeutic agents.

Monoclonal antibodies have become a mainstay in the treatment of patients with relapsing multiple sclerosis (RMS) and provide some benefit to patients with primary progressive MS. They are highly precise by specifically targeting molecules displayed on cells involved in distinct immune mechanisms of MS pathophysiology. They not only differ in the target antigen they recognize but also by the mode of action that generates their therapeutic effect. Natalizumab, an integrin antagonist, works via binding to cell surface receptors, blocking the interaction with their ligands and, in that way, preventing the migration of leukocytes across the blood-brain barrier. On the other hand, the anti-CD52 monoclonal antibody alemtuzumab and the anti-CD20 monoclonal antibodies rituximab, ocrelizumab, ofatumumab, and ublituximab work via eliminating selected pathogenic cell populations. However, potential adverse effects may be serious and can necessitate treatment discontinuation. Most importantly, those are the risk for (opportunistic) infections, but also secondary autoimmune diseases or malignancies. Monoclonal antibodies also carry the risk of infusion/injection-related reactions,

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

primarily in early phases of treatment. By careful patient selection and monitoring during therapy, the occurrence of these potentially serious adverse effects can be minimized. Monoclonal antibodies are characterized by a relatively long pharmacologic half-life and pharmacodynamic effects, which provides advantages such as permitting infrequent dosing, but also creates disadvantages regarding vaccination and family planning. This review presents an overview of currently available monoclonal antibodies for the treatment of RMS, including their mechanism of action, efficacy and safety profile. Furthermore, there are practical recommendations for risk management, vaccination, and family planning.

Antibody-based proteins have become an important class of biologic therapeutics, due in large part to the stability, specificity, and adaptability of the antibody framework. Indeed, antibodies not only have the inherent ability to bind both antigens and endogenous immune receptors but also have proven extremely amenable to protein engineering. Thus, several derivatives of the monoclonal antibody format, including bispecific antibodies, antibody-drug conjugates, and antibody fragments, have demonstrated efficacy for treating human disease, particularly in the fields of immunology and oncology. The considerations for the design of antibody-based therapeutics, including immunological context, therapeutic mechanisms, and engineering strategies. First, characteristics of antibodies are introduced, with emphasis on structural domains, functionally important receptors, isotypic and allotypic differences, and modifications such as glycosylation. Then, aspects of therapeutic antibody design are discussed, including identification of antigen-specific variable regions, choice of expression system, use of multispecific formats, and design of antibody derivatives based on fragmentation, oligomerization, or conjugation to other functional moieties. Finally, strategies to enhance antibody function through protein engineering are reviewed while highlighting the impact of fundamental biophysical properties on protein developability.

Ofatumumab is a fully human anti-CD20 monoclonal antibody that can be self-administered by patients and is approved in several countries worldwide for the treatment of relapsing forms of multiple sclerosis (MS). In two identical phase III trials in adults with relapsing forms of MS, subcutaneous ofatumumab was more effective than oral teriflunomide in reducing the annualized relapse rate, as well as reducing MRI-detected lesion activity and limiting worsening of disability. Ofatumumab had a generally manageable tolerability profile; the most common adverse events (AEs) included nasopharyngitis, headache, upper respiratory tract infections and urinary tract infections. AEs of special interest (AESIs) included infections and injection-related reactions, which were generally manageable. There was no apparent association between changes in immunoglobulin G or M levels and the risk of serious infections after 3.5 years of ofatumumab treatment. Thus, ofatumumab is a convenient treatment option that is effective and has a generally manageable tolerability profile in adults with relapsing forms of MS.

The development of effective monoclonal antibodies for the treatment of myeloma has been a long journey of clinical and drug development. Identification of the right target antigen was a critical part of the process. CD38 as a target has been considered for some time, but clinically, daratumumab, a CD38 monoclonal antibody, was the first to be tested, and it has delivered the best clinical responses as a single agent to date. Its proven safety and efficacy in combination

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

with other antimyeloma agents have led to several US Food and Drug Administration approvals for treating myeloma. Furthermore, the results of early trials in the induction therapy setting have demonstrated a beneficial role when it is added to the existing induction regimens. This review summarizes the importance of CD38 as a target and examines the clinical development of the CD38 monoclonal antibody daratumumab and its clinical significance in combination regimens in both patients with relapsed/refractory myeloma and patients with newly diagnosed myeloma.

Anetumab ravtansine is an antibody–drug conjugate that targets the tumour differentiation antigen mesothelin. Mesothelin is highly expressed in several malignant diseases, including epitheloid mesotheliomas, pancreatic cancer, biliary adenocarcinomas, gastric and ovarian cancers, and non-small-cell lung cancer.⁵⁹ Because expression of mesothelin in healthy human tissue is restricted to mesothelial cells lining the pleura, peritoneum, and pericardium, this target is attractive for antibody–drug conjugate therapy. Anetumab ravtansine is composed of the human anti-mesothelin monoclonal antibody BAY 86–1903 conjugated to the tubulin inhibitor DM4 by a disulphide linker. It binds to human mesothelin with high affinity and selectivity, thereby inducing efficient antigen internalisation. Findings of preclinical studies of anetumab ravtansine showed potent and selective killing of mesothelin-expressing tumours, with a correlation noted between the amount of mesothelin expression and antitumour activity. Moreover, anetumab ravtansine induced a bystander effect on neighbouring mesothelin-negative tumour cells. In the phase 1 clinical trial,⁶⁰ which included tumour types with known high expression of mesothelin, the maximum tolerated dose was defined as 6.5 mg/kg, administered intravenously every 3 weeks. Dose-limiting toxic effects were keratitis and neuropathy. Preliminary results suggest clinical activity, with partial responses reported in seven (18%) of 38 patients treated at the maximum tolerated dose.⁶⁰ Phase 2 investigations are ongoing in mesothelin-expressing cancers (eg, NCT02610140). Inotuzumab ozogamicin is composed of an anti-CD22 monoclonal antibody attached covalently to calicheamicin, a cytotoxic antibiotic.^{61,62} CD22 is a B-cell lineage-restricted type I transmembrane protein and a member of the SIGLEC (sialic acid-binding immuno globulin-like lectins) family of cell-surface receptors. CD22 interacts with diverse sialic acid-bearing molecules present on various cell types—eg, B cells and T cells, neutrophils, and monocytes—to regulate signal transduction of surface immunoglobulin receptors on B cells, B-cell migration, and maintenance of peripheral B-cell tolerance. CD22 is expressed in most B-lymphoid malignant diseases, including non-Hodgkin lymphoma, chronic lymphocytic leukaemia, and acute lymphocytic leukaemia. Inotuzumab ozogamicin has subnanomolar binding affinity and is internalised rapidly to deliver the calicheamicin payload intracellularly.

Monoclonal antibodies have become a part of daily preparation technologies in many laboratories. Attempts have been made to apply monoclonal antibodies to open a new train of thought for clinical treatments of autoimmune diseases, inflammatory diseases, cancer, and other immune-associated diseases. This paper is a prospective review to anticipate that monoclonal antibody application in the treatment of myocarditis, an inflammatory disease of the heart, could be a novel approach in the future. In order to better understand the current state of the art in monoclonal antibody techniques and advance applications in myocarditis. The developed a systematic elaboration of monoclonal antibodies, pathogenesis of myocarditis, and application of monoclonal antibodies in myocarditis. This paper presents review of the literature of some therapeutic aspects of monoclonal antibodies in myocarditis and dilated

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

cardiomyopathy to demonstrate the advance of monoclonal antibody application in myocarditis and a strong anticipation that monoclonal antibody application may supply an effective therapeutic approach to relieve the severity of myocarditis in the future. Under conventional therapy, myocarditis is typically associated with congestive heart failure as a progressive outcome, indicating the need for alternative therapeutic strategies to improve long-term results. Reviewing some therapeutic aspects of monoclonal antibodies in myocarditis, were recently found that monoclonal antibodies with high purity and strong specificity can accurately act on target and achieve definite progress in the treatment of viral myocarditis in rat model and may meet the need above. However, several issues remain. The technology on how to make a higher homologous and weak immunogenic humanized or human source antibody and the treatment mechanism of monoclonal antibodies may provide solutions for these open issues. The further stimulate progress in the area of clinical decision support, must continue to develop and refine our understanding and use of monoclonal antibodies in myocarditis.

Monoclonal antibodies (mAb) are revolutionising the treatment of many different diseases. Given their differing mode of action compared to most conventional chemotherapeutics and small molecule inhibitors, they possess the potential to be independent of common modes of treatment resistance and can typically be combined readily with existing treatments without dose-limiting toxicity. However, treatments with mAb rarely result in cure and so a full understanding of how these reagents work and can be optimised is key for their subsequent improvement. Were review how an understanding of the biology of the inhibitory Fc receptor, Fc γ RIIB (CD32B), is leading to the development of improved mAb treatments. Based on pharmacokinetic parameters of monoclonal antibodies, there is a rationale for fixed dosing of these drugs in oncology. Therefore, the fixed dosing is justified and can improve efficiency of the compounding. A new trend has been taking place in the daily oncology practice in the past twenty years are progressively moving toward individualized and personalized treatments. The treatment of breast cancer is one of the best examples to underline the outstanding effectiveness of the individualized approach. The modern molecular pathology features are capable of predicting the biological behavior of the tumors which gives a new basis for our therapeutic choices, both for neoadjuvant and adjuvant settings, as well as for metastatic disease. Were review the currently used monoclonal antibodies in the treatment of breast cancer and provide an overview of the new research and future directions in this field.

4. CONCLUSION

Monoclonal antibody-based immunotherapy is now considered to be a main component of cancer therapy, alongside surgery, radiation, and chemotherapy. Monoclonal antibodies possess a diverse set of clinically relevant mechanisms of action. In addition, antibodies can directly target tumor cells while simultaneously promoting the induction of long-lasting anti-tumor immune responses. The multifaceted properties of antibodies as a therapeutic platform have led to the development of new cancer treatment strategies that will have major impacts on cancer care. This review focuses on the known mechanisms of action, current clinical applications for the treatment of cancer, and mechanisms of resistance of monoclonal antibody therapy. The further discuss how monoclonal antibody-based strategies have moved towards enhancing anti-tumor immune responses by targeting immune cells instead of tumor antigens as well as some of the current combination therapies.

ABSTRACT

The concept of recycling has been around for decades, but its importance has become more apparent in recent years as we face environmental challenges such as climate change and resource depletion. Recycling is the process of reusing and reusing materials that helps reduce waste and conserve natural resources. Recycling has become an important component of product design and DIY as it helps support sustainability and reduce our impact on the environment. One of the benefits of recycling in design is the use of recycled materials. By using recycled materials in product design, companies can reduce their environmental footprint and conserve natural resources. Today, priority is given to recycled products not only in product design but also in facade design and even in art. However, recycling in design in general also has its challenges. One of the main challenges is finding reliable sources of recycled materials. Companies struggle to find consistent sources of recycled materials. While governments can offer incentives and support to companies that use recycled materials in their products, individuals can make a conscious effort to purchase recycled products and incorporate recycling into their projects. As a result, recycling plays a crucial role in promoting sustainability in design. Individuals and companies can reduce waste, conserve natural resources and encourage creativity and ingenuity by using recycled materials and incorporating recycling into their projects. With education and awareness, we can all play a role in promoting recycling and creating a more sustainable future.

Keywords: Waste Material, Recycling, Design, Product Design, Facade Design.

1. INTRODUCTION

It is the case that short-lived items turn into waste objects when the use time is over, that is, when the item becomes old and the state of usefulness disappears. The shortening of the use time of the goods has become more pronounced with the introduction of mass production completely depending on industrial developments. Mass production has developed in the age of industrialization, and accordingly, a disposable consumption style has emerged in post-industrial societies. Thus, it is seen that the so-called 'waste object' has come to the agenda with modern life (Yılmaz, 2015, 186).

The concept of waste refers to "all kinds of substances and materials that are not used, are not intended to be used, do not have any value and are thrown out". Wastes are generally classified as solid wastes, liquid and gas wastes, packaging wastes, and "substances that do not contain enough liquid to be fluent, should be disposed of in a way that does not harm human and environmental health, and do not work" are defined as solid waste. According to the sources, there are many recovery and disposal methods for solid wastes classified in four groups: domestic solid wastes, industrial qualified solid wastes, medical solid wastes, special solid wastes. These can be sorted as reuse, recycling, recovery, incineration, composting, storage (Tandoğan, 2018, s.190).

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Reuse is the reuse of waste in the same way "without undergoing any treatment other than cleaning". Recycling "is the introduction of waste into the production process as a second raw material after it has been subjected to physical and/or chemical processes". Recycling, on the other hand, is the process of using more than one by "converting the components in it to other products or energy by physical, chemical or biochemical methods by taking advantage of the properties of waste, including the concepts of reuse and recycling" (Tandoğan, 2018, s.190).

2. MATERIALS and METHODS

In this section, the study method, the model, universe and sample of the research, data collection techniques and data analysis are included.

In this research, while theoretical information about the subject is reached through literature research, limitations related to the subject have been introduced with the data collection tool developed specifically for the subject.

3. FINDINGS and DISCUSSION

As the world continues to face environmental challenges, it has become increasingly important to focus on ways to reduce waste and promote sustainability. Recycling is one of the most effective ways to achieve these goals and has the potential to radically change the way we think about product design and Do-It-Yourself.

It is possible to reuse building materials that have reusable qualities in various areas. The reuse of waste building materials is the recovery method with the highest resource and environmental protection due to the fact that it does not require any energy consumption. Structural wastes that are not suitable for reuse are also subjected to a number of recycling processes and are returned to sectoral applications. The structures built using these materials have a positive impact on the country's economy and sustainability (Çuçen & Altuncı, 2022, 193).

Recycling is the process of converting waste materials into new products. By recycling, we can reduce the amount of waste sent to landfills and incinerators, protect natural resources and reduce greenhouse gas emissions. When it comes to product design, there are a number of important benefits of recycling:

1. Reducing waste: By using recycled materials in product design and do-it-yourself projects, we can reduce the amount of waste that goes to landfills and incinerators. This helps to protect natural resources and reduce the environmental impact of our actions.

According to the information obtained from the research, policy makers are carrying out activities to increase the participation of the public in recycling activities, to inform and convince the public. The basic assumption that drives these activities is the fact that recycling will benefit the environment. However, it is not possible for administrations to maximize the benefits of recycling without realizing its potential negative consequences. For this reason, it is very important to go to waste reduction in recycling information studies and to explain the possibilities of reuse to individuals (Tufaner, 2019, 34).

2. Protecting natural resources: Recycling helps protect natural resources such as timber, minerals and water. By using recycled materials, we can reduce the need to extract these resources from the earth, which help protect natural habitats and ecosystems.

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

Waste has been expressed as the difference between the amount of resources owned and the amount needed Decently. Waste arises from the use of more resources than necessary or the inefficient use of resources. In everyday life, most individuals knowingly or unknowingly waste resources and damage natural resources. Therefore, the reduction of feelings related to wasteful consumption comes across as a process that precedes recycling activities (Tufaner, 2019, 34).

3. Reducing greenhouse gas emissions: Recycling also helps to reduce greenhouse gas emissions. When materials are recycled, it requires less energy than producing new materials from scratch. This means burning fewer fossil fuels, which helps reduce the amount of carbon dioxide and other greenhouse gases released into the atmosphere.

4. Promoting sustainability: By incorporating recycling into product design and Do-It-Yourself projects, we can promote sustainability and raise awareness of the importance of reducing waste and protecting natural resources. This can inspire others to take action and make sustainable choices in their own lives.

Jul can contribute to waste management through information and awareness-raising activities in order to contribute to the country's economy in an effort to leave a sustainable clean environment and a clean world to future generations, especially with recycling that will suppress the feeling of extravagance. Especially in order to suppress the feeling of extravagance, it can contribute to waste management through information and awareness (Tufaner, 2019, 34).

Figure 1. Güell Park, Barselona-Spain, 1926 (Küplemez & Güngör, 2023, 48).

Gaudí used ceramic materials to be close to people and nature and achieved an artistic appearance with thousands of broken ceramic pieces. At the same time, the bench is both waterproof and health-friendly because it is covered with mosaic. One of the reasons Gaudí prefers ceramic material is that ceramic material is economical. Gaudí obtained the ceramics he used by using the waste parts of faulty products produced in factories. Color plays an important role in Gaudí's designs. Ceramic material offers convenience in providing a variety of colors and is also preferred due to its durability (Figure 2) (Küplemez & Güngör, 2023, 48).

Figure 2. Chybik+Kristof Architects & Urban Design, Brno, CZ, 2015-2016 (www.chybik-kristof.com, 2023)

The new furniture showroom is located on the outskirts of a public housing estate in Brno. The existing building was not suitable for the proposed function from a formal point of view. There are two sides to the concept; the first involves working with the interior and focusing on the presentation of a wide range of products that the company produces or distributes. The spacious interior is divided into sections by a system of spaces defined by suspended curtains. The second side of the concept solves the design of personnel facilities, consisting of offices, warehouses and technical and sanitary facilities. The new outdoor shell consists of the structure of the chairs produced by the company (<https://www.chybik-kristof.com/projects/gallery-of-furniture>, Erişim tarihi:17.07.2023).

Figure 3. Endless Chair, Dirk Van Der Kooij, 2011 (dirkvanderkooij.com, 2023)

In 2011, the Endless chair was realized as Dirk van der Kooij's challenging graduation project. In a world first, he had reconfigured a pneumatic robotic arm to remove furniture from recycled plastic. The first series consisted of lightly colored plastic threads, shakily formed to form 3-D tapestries. A misaligned motor was creating a fistulous pattern, but it was also responsible for an unexpectedly veiled use of the technique (<https://dirkvanderkooij.com/endsless-chair>, (Access Date: 13.07.2023).

One way to incorporate recycling into product design is to use recycled materials in the manufacturing process. This could include using recycled plastic, paper and metal to create new products. Many companies are already doing this, and it has become an important trend in the manufacturing industry.

Figure 4. Sculptural Design, Charlotte Kidger (www.charlottekidger.com, 2023)

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Kidger is a London-based producer who researches how industrial waste materials can be reprocessed and transformed into sculptural and functional objects. Their furniture and home accessories are made of polyurethane foam powder, which is a waste material of creating industrial-scale 3D models on CNC machines, and hand-painted resin, which is cold poured into molds. "Designers are starting to see waste as a new form of raw material due to the extraordinary volumes of various waste streams that surround us," he says. Companies with materials that have no residual or residual value will have to install systems to ensure that these materials enter new production cycles."

Charlotte Kidger is a London-based UK Maker (b. 1992). Kidger graduated from Leeds College of Art BA (2014) and Central Saint Martins MA (2018) and has a background in Molding, Casting and Sculpture, based on industrial by-products. Her practice is led by a hands-on approach to exploring how these undervalued resources can be reused to reconnect people with our material world. Often marrying unconventional sources and processes, he aims to reframe material values through carefully crafted works and installations. Ongoing research on material extraction, by-products and craft processes means that new ideas and concepts are constantly evolving. Charlotte hopes to bring alternative perspectives to new audiences through sensory experiences and storytelling (<https://www.charlottekidger.com/bio>, Access Date: 20.07.2023).

4. CONCLUSION and RECOMMENDATIONS

Finally, we can summarize the key points we have mentioned and re-state the importance of recycling in product design. You can also offer some final thoughts or advice for readers who want to incorporate recycling into their own projects.

As a result, recycling is an important part of promoting sustainability and reducing waste. When it comes to product design, recycling has the potential to radically change the way we think about creating and consuming goods. By including recycling in our projects, we can help protect natural resources, reduce greenhouse gas emissions and promote a more sustainable future for everyone.

ABSTRACT

Museums are structures where objects of artistic, cultural and historical value are exhibited. Carrying traces from the past to the present, museums fulfil various functions such as conservation, research and communication as well as their basic functions of collection and accumulation. Museology is a discipline that deals with many processes from the protection of collections to their exhibition. Today, the understanding of museology has become a contemporary approach that evolves according to the needs of the age and the changing needs of society, as well as the traditional role of museums. Museums are divided into different types according to the artefacts they exhibit. Toy museums are one of the types of museums that exhibit the history, diversity and cultural importance of toys. These types of museums provide both an entertaining experience for visitors who want to revive memories of the past of toys and provide an instructive environment by sharing the historical and cultural values of toys. In this study, it is aimed to reveal the spatial organisation, diversity and exhibition space design of toy museums that emphasise the universal language of toys and their impact on people's imagination. On-site identification, photography and observation studies were carried out in Samsun Canik Toy Museum, which was determined as the study area. It has been observed that especially colour and lighting designs are at the forefront in the exhibition units and spaces of Samsun Canik Toy Museum. However, it has been suggested that service and/or other additional units should be included in the design in this direction.

Keywords: Toy Museum, Exhibition Space, Interior Design, Samsun.

1. INTRODUCTION

The word museum, whose etymology dates back to antiquity, derives from the Greek word "Mouseion", which means the place of reflection of the muses of science and art in the Hellenistic period. Then, in the Late Renaissance, it was called the Latin equivalent museum, which means the place where collections are kept, and today it has taken its place as a Museum (Madran, 2022). According to the Turkish Language Association (2023), museums are defined as places where works of art and science are kept and exhibited. According to the definition in the Internal Regulation on Museums of the Ministry of Culture and Tourism of the Republic of Türkiye (1990), museums are institutions that identify, examine, preserve and exhibit historical artefacts, and on the other hand, raise public awareness and raise the cultural level of society through various educational programmes. When we look at the definition of museums in the international literature, according to the International Council of Museums (2022), they are

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

non-profit, community-serving structures that collect, research and exhibit tangible and intangible heritage values.

Museums have various functions including conservation, research, exhibition and communication. The conservation function focuses on the care of artefacts and collection building, extending the exhibition period of artefacts and ensuring their safety against any damage that may occur, while the research function includes research on artefacts. The display function is related to the arrangement of artefacts in a way that is suitable for visitors, while the communication function focuses on attracting the attention of visitors, discovering their needs and meeting their intellectual needs (Hooper-Greenhill, 1999; Erbay, 2017). The traditional understanding of museology supports the basic functions of museums and today, the understanding of museology is constantly developing and transforming in accordance with the changing needs and expectations of society. According to this understanding, visitor orientation, visitor participation, various educational services, social responsibility and sustainability, cultural inclusiveness, digitalisation and multidisciplinary approaches are at the forefront (Okan, 2015; Karadeniz et al., 2015; Onur, 2014).

Museums, which are classified according to the artefacts they exhibit, can be classified as art museums, history museums, ethnography museums, science and technology museums, archaeology museums and specialisation museums (United Nations Educational, Scientific and Cultural Organization, 1998). In this study, toy museums, which are in the category of speciality museums focusing on a specific subject or theme, are discussed. In toy museums, where different toys that attract the attention of visitors of all ages are exhibited, space diversity, organisation style and exhibition area designs were examined within the scope of the study.

1.1. Toy Museums

Various toys and play materials are exhibited in toy museums, which serve as a bridge between the past and the future. Its main purpose is to protect, research and transfer the game and toy culture to future generations (Ersoy İnci, 2013). Although the visitor audience is mainly made up of children, these museums today also attract the attention of many adults. These museums, which appeal to all ages, also enable the development of intergenerational communication (Karadeniz & Artar, 2018). The toys exhibited in the museum give visitors information about the play culture of the period. In other words, these museums offer visitors the opportunity to discover the development and change of toys in the historical process (Erbay, 2017). Toys, which are a tangible means of entertainment, reflect the historical, cultural, economic and social life of the period in which they were made (Niemann & Onur, 2019). It especially contributes to children's social, mental, emotional and physical development skills. In toy museums, visitors also see the traces of the change in the culture of play through toys. In these museums, toys are categorised in various ways, especially the period in which they were produced or the material from which they were produced. In some toy museums, toys are categorised as traditional, antique, fabricated and digital toys, while in others, toys can be exhibited in material-oriented categories such as wood, cloth, metal and porcelain (Erbay, 2017; Akoğlan Kozak & Güncan, 2021).

1.1.1. Toy Museums From Around the World

The number of toy museums is rapidly increasing in the metropolises of developed countries in the world. Toy museums that research and exhibit games, toys and children's culture in many countries from the United States of America to Japan, especially in European countries such as

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

England, Germany and France, are in an active functioning (Karadeniz & Atar, 2017; Mankırcı, 2018; Genç, 2019; Akoğlan Kozak & Güncan, 2021). In this section, some toy museums around the world are included.

England, Pollok's Toy Museum: Founded in 1856 by Benjamin Pollock, the Pollock Toy Museum is the first toy museum in the world (Mankırcı, 2018). Located in a historic building in London, the museum has a rich collection of toy theatres. The collections in the museum were created with various purchases, donations from friends, family and the public. In the museum, which has six exhibition rooms; toys from various parts of the world such as dolls and doll houses, tin and cardboard toys, teddy bears are exhibited. At the entrance of the museum, there is an information desk, a box office and a sales section where certain toy replicas are sold (Mankırcı, 2018; Köse, 2020) (Figure 1).

Figure 1. Pollok's Toy Museum (URL, 1)

Germany, Nürnberg Toy Museum: Nürnberg Toy Museum, one of the first and largest toy museums in Germany, was opened to visitors in 1971 (Daşçı, 2014). The museum exhibits toys of cultural and historical significance from Germany and other countries. The museum collection consists mainly of toy kitchens, wooden and tin toys, toy animals and trains from the 18th and 19th centuries (Çıldır, 2014). Located in a historical building, the entrance section of the museum houses a box office, information desk and sales units. In addition to the exhibition, there is a playground, café and event areas (Genç, 2019) (Figure 2).

Figure 2. Nürnberg Toy Museum (URL, 2; URL, 3)

France, Poissy Toy Museum: Poissy Toy Museum was founded in 1972 in Poissy, France. Located in a historical building, the museum has a collection of various toys from the 17th and 20th centuries. In this collection, there is a wide variety from craft toys such as rattles, cars,

TeMALab

Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

animals, dolls to industrial toys (Mankırcı, 2018). The educational activities and contents of the museum are organised in the categories of storytelling, handicrafts and creativity workshops (Köse, 2020) (Figure 3).

Figure 3. Poissy Toy Museum (URL, 4)

Japan, Japan Toy Museum: The Japan Toy Museum is located in a rural area about 10 kilometres north of Himeji, Japan. Founded in 1974, the museum's collection consists of various toys collected from 160 countries, especially Japanese folk toys (Mankırcı, 2018). The museum has 6 traditional interiors with special play corners. In addition to permanent exhibitions, special and seasonal exhibitions are organised in the museum (Genç, 2019) (Figure 4).

Figure 4. Japonya Toy Museum (URL, 5)

United States of America, The Great American Dollhouse Toy Museum: This museum in America was established in 2006. The toys exhibited in the museum are exhibited both physically and in terms of the story they tell. The toys exhibited in a chronological order also shed light on the history of the United States of America. Located in a historic building, the museum consists of three main exhibition halls (Genç, 2019) (Figure 5).

Figure 5. The Great American Dollhouse Toy Museum (URL, 6)

1.1.2. Toy Museums From Türkiye

With the diversification of museum types in Türkiye, toy museums have also started to exist. The first example of toy museums in Türkiye is accepted as Ankara University Faculty of Educational Sciences Toy Museum (Karadeniz & Atar, 2017; Akođlan Kozak & Güncan, 2021). Istanbul Toy Museum, İzmir Ümran Baradan Play and Toy Museum, Antalya Toy Museum, Gaziantep Play and Toy Museum were the other museums opened to visitors in time. Anatolian Toy Museum in Antalya and Canik Toy Museum in Samsun are the museums opened to visitors in recent years (Köse, 2020). In this section, some toy museums in Türkiye are included.

Türkiye, Ankara University Faculty of Educational Sciences Toy Museum: Türkiye's first toy museum is Ankara University Faculty of Educational Sciences Toy Museum, which was opened in 1990. In the museum, which also serves as a research and education centre, nearly three thousand toys are divided into five main groups: traditional, fabricated, foreign, antique and new (Köse, 2020). There are many toys made of various materials such as wood, tin, paper and plastic in the museum. Temporary exhibitions and meetings are organised and the museum also hosts various activities such as doll making workshops and origami workshops (Erbay, 2017; Genç, 2019; Akođlan Kozak & Güncan, 2021). Located on the campus of Ankara University, the museum has administration, library and activity workshop in addition to exhibition spaces (Dıvrak, 2017) (Figure 6).

Figure 6. Ankara University Faculty of Educational Sciences Toy Museum (URL, 7)

TeMALab
Department of Civil, Building and Environmental Engineering
University of Naples "Federico II"

III. International Architectural Sciences and Applications Symposium
September 14-15, 2023, Naples, Italy

Türkiye, Istanbul Toy Museum: Istanbul Toy Museum was founded in 2005 by poet-writer Sunay Akin. It is recognised as Türkiye's second toy Museum (Ellibeş, 2016). In the museum, where various toys from the 1700s to the present day are exhibited, the artefacts were purchased from antique dealers in more than 40 countries. The museum, which houses more than 4000 toys, is located in a five-storey historical building. The toys in the museum are grouped and exhibited according to their themes (Mankırcı, 2018). In addition to the exhibition function, various workshops for children, theatre and documentary screenings are held. The exhibition spaces in the museum are supported by a café, workshop and garden (Figure 7).

Figure 7. Istanbul Toy Museums (Genç, 2019)

Türkiye, İzmir Ümran Baradan Play and Toy Museum: The foundations of Ümran Baradan Play and Toy Museum were laid by ceramic artist Ümran Baradan in Izmir in 2004 (Dıvrak, 2017). In 2010, under the conceptual consultancy of Sunay Akin, the existing collection was enriched and taken over by Konak Municipality. The museum exhibits approximately 1000 pieces of artefacts including rag dolls, plush toys, antique toys, metal toys, toy transport vehicles, space vehicles and interactive toys (Mankırcı, 2018; Akoğlan Kozak & Güncan, 2021). Various educational, activity and interactive applications are organised in the museum. One part of the two-storey museum building is organised as an event hall (Figure 8).

Figure 8. İzmir Ümran Baradan Play and Toy Museum (Genç, 2019)

Türkiye, Antalya Toy Museum: Antalya Toy Museum was opened by Antalya Metropolitan Municipality in Kaleiçi in 2011. More than 3000 toys from the 1860s to the present day are exhibited in the museum (Erbay, 2017). The collection also includes toys produced by domestic and foreign toy manufacturers (Akoğlan Kozak & Güncan, 2021). The museum, whose programme is enriched with workshop activities and seminars, has 11 exhibition halls. Antalya

Toy Museum is built on an area of approximately 700 square metres and consists of two buildings connected by an inner courtyard and an independent two-storey workshop building (Dıvrak, 2017) (Figure 9).

Figure 9. Antalya Toy Museum (URL, 8)

Türkiye, Gaziantep Play and Toy Museum: Gaziantep Play and Toy Museum was opened to visitors in 2013 by Gaziantep Metropolitan Municipality. The collection of the museum consists of approximately 3000 toys brought from different countries such as the United States of America, Germany and Japan from the period 1700-1990 (Köse, 2020). In the museum; special exhibition sections have been created with collection titles such as cinema room, kitchen room, social life room, golden room, wooden room, plush toys room and cave. The museum, where various workshop activities are also held, is located in a historical Gaziantep house built in the 1700s. This three-storey house with a courtyard was adapted to the museum function with its two-storey cave and the management and activity workshop added to the courtyard (Genç, 2019) (Figure 10).

Figure 10. Gaziantep Play and Toy Museum (URL, 9)

2. MATERIALS and METHODS

In this study, which aims to reveal the space organisation, space diversity and exhibition space design of toy museums, a comprehensive literature review on museums, museum types and toy museums was carried out in the first stage. Then, in the second stage, the study area was determined. In this direction, Samsun Canik Play Museum, one of the largest toy museums in Türkiye (URL, 10), was selected as the study area (Figure 11).

Figure 11. Study area

The museum is located in Canik district, one of the central districts of Samsun province. In the Canik Toy Museum, whose concept consultant is Sunay Akın, the founder of Istanbul Toy Museum, nearly a thousand toys in various categories including traditional, fabricated, antique domestic and foreign toys produced between 1800 and 1980 are exhibited (URL, 10). The museum is open to visitors between 10.00 and 16.00 every day except Sundays and Mondays and the entrance is free of charge. In the third stage of the study, architectural drawings of the building were obtained from the archive of the district municipality, and then a field study was carried out by on-site observation and photography. In the light of the data obtained from the field study, the Hillier access graph was drawn and analyses were carried out for the design of the exhibition spaces.

3. FINDINGS and DISCUSSION

The museum building consists of a rectangular ground floor and a basement. On the ground floor of the building, there are information desk, exhibition halls, cafeteria, sales section, toy workshop, wet areas and system room. On the ground floor, there is a storage room, staff resting area and theatre hall. Consisting of 16 spaces, it was observed that the entrance space, which provides distribution in the access graph of the museum consisting of 16 spaces, is the space with the maximum point value. However, the exhibition halls are designed in a way to allow the circulation of the visitor and the exhibition spaces are in the nature of transition spaces. The workshop, sales and cafeteria spaces in the museum appear as terminal spaces that do not allow passage through. On the other hand, it has been observed that the system room and the theatre hall form a loop by establishing a relationship with the outdoor space. The relationship of these spaces with the exterior space provides convenience both for the evacuation of the theatre hall,

III. International Architectural Sciences and Applications Symposium September 14-15, 2023, Naples, Italy

which is crowded from time to time, and for access to the system room for intervention in case of any system malfunction (Figure 12).

Figure 12. Canik Toy Museum entrance and basement floor plans (top), access graphic (bottom)

The types and sizes of the exhibited artefacts differed, as well as the way they were exhibited. In addition to toys, two-dimensional paintings reflecting the play culture of the period in which they were made are among the exhibited artefacts (Figure 13).

Although the exhibition space in the museum has an open plan type, the walls help to direct the visitors' visit experiences and create an exploratory atmosphere. On the other hand, part of the space consists of small rooms depending on the concept of the exhibited toys. Although there is no visitor entrance to these areas, the rooms where the artefacts are exhibited are open to the visitors' experience through transparent surfaces. Natural lighting is not utilised in the illumination of the exhibition space and the whole space is illuminated only by artificial lighting elements. There are LED recessed spotlights in the space, which have an important place in both providing the visual comfort conditions of the visitors and spreading the light homogeneously throughout the space. While these form the general illumination of the space, on the other hand, it was tried to increase the attractiveness of the space with different light coloured projector illuminations, especially blue and red colours (Figure 14). A gloomy atmosphere has been created by preferring dark colours on the surfaces. On the other hand, it is aimed for visitors to experience the fairy-tale atmosphere of the world of games and toys with the use of light in different colour tones on dark surfaces.

Figure 14. Exhibition spaces in the museum

In the exhibition area, artefacts are exhibited in three types: niches on the wall surface, showcase type exhibition elements and toy rooms. The niches formed on the wall surface are covered with glass surfaces in order to protect from changes in the humidity and temperature level of the space, taking into account the security requirement. In these areas, mainly small-sized single toys were exhibited and illuminated with regional lighting elements. On the other hand, there are glazed wall-type showcases in the exhibition halls that allow the toys to be seen from a single axis. In these sections, mainly thematic toys or limited edition collection toys produced by a country between certain periods are exhibited. These showcases are illuminated with lighting placed on the ceiling of the showcase (Figure 15).

Glazed showcases played an effective role in protecting the toys from physical contact. In the toy rooms, mainly handmade model toys, puppets and various children's play books are exhibited and general and regional lighting is used in these rooms.

4. CONCLUSION and RECOMMENDATIONS

In this study, the spatial organisation and the design of exhibition spaces in toy museums aiming to preserve the culture of games and toys and to transfer them to future generations were analysed. Considering the spatial relations of the museum, it can be said that the main space that provides distribution to the museum is the entrance space and thus all the spaces of the museum are controlled. It can be argued that the fact that the exhibition halls are located at a separate point from other service spaces and that they are independent within themselves is aimed to remove these spaces from the effects of the external environment in experiencing these spaces. The fact that other spaces such as workshops, cafeterias, sales units and theatres are independent from the exhibition areas allows the museum to be experienced separately with all its elements. It can be said that the fact that only artificial lighting is preferred in the space leads to disadvantageous situations in terms of economy and energy consumption. It is thought that the inclusion of natural lighting in the exhibition area in a controlled manner will facilitate the visual comfort of the visitors and their perception of the space and the toys exhibited. On the other hand, the preference of dark colours in the space weakens the perception of the space by the visitors. It is clear that surface colours make the space appear more depressive and gloomy than it actually looks. Especially on the floor and wall surfaces, it is thought that the use of lighter colours will both make the exhibited toys more prominent and create a more pleasant space atmosphere. However, it can also be argued that the use of this colour creates a fairy-tale environment with artificial lighting. In addition to the general lighting of the space, it is thought that the reconstruction of the location and colours of different coloured light sources preferred in the space will positively affect the atmosphere of the space. The preference for different forms of display in the exhibition area has allowed for diversity in the organisation and organisation of the toys. Glare and reflections were observed in the exhibition areas with glass surfaces. This situation can be solved by reducing the light intensity in these areas so as not to prevent the correct perception of the artefact. On the other hand, it can be reduced by using different types of glass such as matt glass or anti-reflective glass. When the relevant literature is reviewed, it is thought that this study contributes to the awareness of the building since there is no study on Canik Toy Museum in the literature. However, it is an indicator of the increase in the importance given to museums and museology in Türkiye and the increase in the number and types of museums.
